->10.11.201.0/24 (->x.x.x.x/mask)	The IP address and subnet mask of the destination
pref	Preferred next hop along this route
gwy	Gateway: The address of the gateway this route will use
dev	Outgoing interface index: This number is associated with the interface for this route. If VDOMs are enabled, the VDOM is also included here. If an interface alias is set for this interface, it is also displayed here.

Searching the routing table

You can apply a filter to search the routing table and display only certain routes. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed. An implicit AND condition is applied to all of the search parameters you specify.

For example, if the FortiGate is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select **Connected** from the **Type** list, type 172.16.14.0/24 in the **Network** field, and then select **Apply Filter** to display the associated routing table entry or entries. Any entry that contains the word "Connected" in its **Type** field and the specified value in the **Gateway** field will be displayed.

In this example, you will apply a filter to search for an entry for static route to 10.10.10.10/24.

To search the routing table routing table - GUI:

1. Go to **Monitor > Routing Monitor**.
2. From the **Type** list, select the type of route to display. In this example, select **Static**.
3. If you want to display routes to a specific network, type the IP address and netmask of the network in the **Networks** field. In our example, enter 10.10.10.10/24.
4. If you want to display routes to a specific gateway, type the IP address of the gateway in the **Gateway** field.
5. Select **Apply Filter**.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

To search the routing table - CLI:

```
FGT # get router info routing-table details 10.10.10.10
Routing entry for 10.10.10.10/24
  Known via "static", distance 10, metric 0, best
```

If there are multiple routes that match your filter, they will all be listed and the best match will be at the top of the list and indicated by the word "best".

Building the routing table

In factory default configuration, the routing table on the FortiGate contains a single static default route. You can add routing information to the routing table by defining additional static routes.

It's possible that the routing table is faced with several different routes to the same destination - the IP addresses of the next-hop router specified in those routes or the FortiGate interfaces associated with those routes may vary. In this situation, the best route is selected from the table.

The FortiGate selects the best route for a packet by evaluating the information in the routing table. The best route to a destination is typically associated with the shortest distance between the FortiGate and the closest

gateway, also known as a next-hop router. In some cases, the next best route may be selected if the best route is unavailable.

The FortiGate installs the best available routes in the forwarding table, which is a subset of the routing table. Packets are forwarded according to the information in the forwarding table.

Static routing security

Securing the information on your company network is a top priority for network administrators. Security is also required as the routing protocols used are internationally known standards that typically provide little or no inherent security by themselves.

The two reasons for securing your network are the sensitive and proprietary information on your network and also your external bandwidth. Hackers can steal not only your information, but they can also steal your bandwidth. Routing is a good low-level way to secure your network, even before UTM features are applied.

Routing provides security to your network in a number of ways including obscuring internal network addresses with NAT and blackhole routing, using RPF to validate traffic sources, and maintaining an access control list (ACL) to limit access to the network.

Network Address Translation

Network address translation (NAT) is a method of changing the address from which traffic appears to originate. This practice is used to hide the IP address on a company's internal networks and helps prevent malicious attacks that use those specific addresses.

This is accomplished by the router connected to that local network changing all the IP addresses to its externally connected IP address before sending the traffic out to the other networks, such as the Internet. Incoming traffic uses the established sessions to determine which traffic goes to which internal IP address. This also has the benefit of requiring only the router to be very secure against external attacks, instead of the entire internal network, as would be the case without NAT. Securing the network is much cheaper and easier to maintain.

Configuring NAT on a FortiGate includes the following steps:

1. Configure your internal network. For example, use the `10.11.101.0` subnet.
2. Connect your internal subnet to an interface on the FortiGate. For example, use `port1`.
3. Connect your external connection (for example, an ISP gateway of `172.20.120.2`) to another interface on the FortiGate (for example, `port2`).

Configure security policies to allow traffic between `port1` and `port2` on the FortiGate, ensuring that the NAT feature is enabled.

The above steps show that traffic from your internal network will originate on the `10.11.101.0` subnet and pass on to the `172.20.120.0` network. The FortiGate moves the traffic to the proper subnet. In doing that, the traffic appears to originate from the FortiGate interface on that subnet and it doesn't appear to originate from where it actually came from.

NAT "hides" the internal network from the external network. This provides security through obscurity. If a hacker tries to directly access your network, they will find the FortiGate, but they won't know about your internal network. The hacker would have to get past the security-hardened FortiGate to gain access to your internal network. NAT won't prevent hacking attempts that piggy back on valid connections between the internal network and the outside world. However, other UTM security measures can deal with these attempts.

Another security aspect of NAT is that many programs and services have problems with NAT. Consider if someone on the Internet tries to initiate a chat with someone on the internal network. The outsider can access

only the external interface on the FortiGate, unless the security policy allows the traffic through to the internal network. If allowed in, the correct internal user would respond to the chat. However, if it's not allowed, the request to chat will be refused or it will time out. This is accomplished in the security policy by allowing or denying different protocols.

Access control list

An access control list (ACL) is a table of addresses that have permission to send and receive data over a router's interface or interfaces. The router maintains an ACL, and when traffic comes in on a particular interface it's buffered, while the router checks the ACL to see if that traffic is allowed over that port. If it's allowed on that incoming interface, the next step is to check the ACL for the destination interface. If the traffic also passes that check, the buffered traffic is delivered to its destination. If either of those steps fail the ACL check, the traffic is dropped and an error message may be sent to the sender. The ACL ensures that traffic follows expected paths and any unexpected traffic isn't delivered. This stops many network attacks. However, to be effective, the ACL must be kept up to date. When employees or computers are removed from the internal network, their IP addresses must also be removed from the ACL. For more information about the ACL, see the router chapter of the [FortiOS CLI Reference](#).

Blackhole routes

A blackhole route is a route that drops all traffic sent to it. It is very much like `/dev/null` in Linux programming.

Blackhole routes are used to dispose of packets instead of responding to suspicious inquiries. This provides added security since the originator won't discover any information from the target network.

Blackhole routes can also limit traffic on a subnet. If some subnet addresses aren't in use, traffic to those addresses, which may be valid or malicious, can be directed to a blackhole for added security and to reduce traffic on the subnet.

The loopback interface, which is a virtual interface that doesn't forward traffic, was added to allow easier configuration of blackhole routing. Similar to a regular interface, the loopback interface has fewer parameters to configure and all traffic sent to it stops there. Since it can't have hardware connection or link status problems, it's always available, making it useful for other dynamic routing roles. Once configured, you can use a loopback interface in security policies, routing, and other places that refer to interfaces. You configure this feature only from the CLI. For more information, see the system chapter of the [FortiOS CLI Reference](#).

Configuring IPv6 blackhole routes

You can configure IPv6 blackhole routes. In the FortiGate GUI, select **Network > Static Routes** and select **Create New**. In the **Interface** field, choose **Blackhole**.

Blackhole static routing

System administrators use blackhole routing to divert unwanted traffic, such as packets from a Denial of Service (DoS) attack or communications from an illegal source. The traffic is routed to a dead interface, or a host designed to collect information for investigation. This mitigates the impact of the attack on the network.

To enable blackhole routing - CLI:

```
config router {static|static6}
  edit <sequence number>
    set blackhole enable
  next
end
```

Blackhole route priority

You can add a priority to a blackhole route to change its position relative to kernel routes in the routing table.

To add a blackhole route with a priority - CLI:

```
config router static
  edit <sequence number>
    set blackhole enable
    set priority 200
  next
end
```

Static routes and VRFs

You can configure static route support for multiple virtual routing and forwarding (VRFs) on a FortiGate.

To add VRFs for blackhole routes - CLI:

```
config router static
  edit <sequence-number>
    set vrf <VRF-ID>
  end
```

where `vrf` is a value of 0 to 31

Reverse path lookup

Whenever a packet arrives at one of the interfaces on the FortiGate, the FortiGate determines whether the packet was received on a legitimate interface by doing a reverse lookup using the source IP address in the packet header. This is also called anti-spoofing. If the FortiGate can't communicate with the computer at the source IP address through the interface on which the packet was received, the FortiGate drops the packet as it's likely a hacking attempt.

If the destination address can be matched to a local address, and the local configuration permits delivery, the FortiGate delivers the packet to the local network. If the packet is destined for another network, the Fortigate forwards the packet to a next-hop router according to a policy route and the information stored in the FortiGate forwarding table.

Multipath routing and determining the best route

Multipath routing occurs when more than one entry to the same destination is present in the routing table. When multipath routing happens, the FortiGate may have several possible destinations for an incoming packet, forcing the FortiGate to decide which next-hop is the best one.

It should be noted that some IP addresses will be rejected by routing protocols. These are called Martian addresses. They are typically IP addresses that are invalid and not routable because they have been assigned an address by a misconfigured system, or are spoofed addresses.

Two methods to manually resolve multiple routes to the same destination are to lower the administrative distance of one route or to set the priority of both routes. For the FortiGate to select a primary (preferred) route, manually lower the administrative distance associated with one of the possible routes. Setting the priority on the routes is a FortiGate feature and may not be supported by routers that aren't Fortinet products.

Administrative distance is based on the expected reliability of a given route. It's determined through a combination of the number of hops from the source and the protocol used. A hop is when traffic moves from one router to the next. More hops from the source means more possible points of failure. The administrative distance can be in the range of 1 to 255, with lower numbers being preferred. A distance of 255 is seen as infinite and won't be installed in the routing table.

Here's an example to illustrate how administration distance works. If there are two possible routes traffic can take between two destinations, with administration distances of 5 (always up) and 31 (sometimes not available), the traffic will use the route with an administrative distance of 5. If for some reason the preferred route (admin distance of 5) isn't available, the other route will be used as a backup.

Different routing protocols have different default administrative distances. These different administrative distances are based on a number of factors of each protocol such as reliability, speed, and so on. You can configure the default administrative distances for any of these routing protocols.

Default administrative distances for routing protocols and connections

Routing protocol	Default administrative distance
Direct physical connection	1
Static	10
EBGP	20
OSPF	110
IS-IS	115
RIP	120
IBGP	200

Another method to determine the best route is to manually change the priority of both routes in question. If the next-hop administrative distances of two routes on the FortiGate are equal, it may not be clear which route the packet will take. Manually configuring the priority for each of those routes will make it clear which next-hop will be used in the case of a tie. The priority for a route can be set in the CLI, or when editing a specific static route, as

described in the next section. Lower priority routes are preferred. Priority is a Fortinet value that may or may not be present in other brands of routers.

All entries in the routing table are associated with an administrative distance. If the routing table contains several entries that point to the same destination (the entries may have different gateways or interface associations), the FortiGate compares the administrative distances of those entries first, selects the entries having the lowest distances, and installs them as routes in the FortiGate forwarding table. As a result, the FortiGate forwarding table contains only those routes that have the lowest distances to every possible destination. While only static routing uses administrative distance as its routing metric, other routing protocols, such as RIP, can use metrics that are similar to administrative distance.

Route priority

After a FortiGate selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can configure the priority field through the CLI or the GUI. Priority values can range from 0 to 4 294 967 295. The route with the lowest value in the priority field is considered the best route. It's also the primary route.

To change the priority of a route - GUI:

1. Go to **Network > Static Routes**.
2. Select the route entry, and select **Edit**.
3. Select **Advanced Options**.
4. Enter the **Priority** value.
5. Select **OK**.

To change the priority of a route - CLI:

The following command changes the priority to 5 for a route to the address 10.10.10.1 on the port1 interface.

```
config router static
  edit 1
    set device port1
    set gateway 10.10.10.10
    set dst 10.10.10.1
    set priority 5
  next
end
```

If there are other routes set to priority 10, the route set to priority 5 will be preferred. If there are routes set to priorities less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal-cost multi-path (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, different sessions will resolve this problem by using different routes to the same address.

Use of firewall addresses for static route destinations

To help prevent false positive when scanning for duplicate static routes, the `dst_addr` field is also checked.

Removing RPF checks from the state evaluation process

You can remove RPF (reverse path forwarding) state checks without needing to enable asymmetric routing. You can disable state checks for traffic received on specific interfaces.

Disabling state checks makes a FortiGate less secure and should only be done with caution.

To remove RPF checks from the state evaluation process - CLI:

```
config system interface
  edit <interface_name>
    set src-check disable
  next
end
```

Troubleshooting static routing

When there are problems with your network that you think are related to static routing, there are a few basic tools available to locate the problem. These tools include ping, traceroute, and examining routing table contents.

Ping

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there's no packet loss detected, your basic network connectivity is okay.

If there's some packet loss detected, you should investigate:

- Possible ECMP, split horizon, network loops
- Cabling to ensure no loose connections

If there's total packet loss, you should investigate:

- Hardware: Ensure cabling is correct, and all equipment between the two locations is accounted for
- Addresses and routes: Ensure all IP addresses and routing information along the route is configured as expected
- Firewalls: Ensure all firewalls are set to allow PING to pass through

To ping from a Windows PC:

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter `cmd` and select **OK**.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate with four packets.

To ping from an Apple computer:

1. Open the Terminal.
2. Enter `ping 10.11.101.100`.
3. If the ping fails, it will stop after a set number of attempts. If it succeeds, it will continue to ping repeatedly. Press `Control+C` to end the attempt and see gathered data.

To ping from a Linux PC:

1. Go to a command line prompt.
2. Enter `"/bin/etc/ping 10.11.101.101"`.

Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, you can use traceroute to locate exactly where the problem is.

To use traceroute on a Windows PC:

1. Go to a DOS prompt. Typically you go to **Start > Run**, enter `cmd` and select **OK**.
2. Enter `"tracert fortinet.com"` to trace the route from the PC to the Fortinet website.

To use traceroute from an Apple computer:

1. Open the Terminal.
2. Enter `traceroute fortinet.com`.
3. The terminal will list the number of steps made. Upon reaching the destination, it will list three asterisks per line. Press `Control+C` to end the attempt.

To use traceroute on a Linux PC:

1. Go to a command line prompt.
2. Enter `"/bin/etc/traceroute fortinet.com"`.
The Linux traceroute output is very similar to the MS Windows traceroute output.

Examine routing table contents

The first place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route isn't used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. Note that if a FortiGate is in transparent mode, you won't be able to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the GUI, use the Routing Monitor. Go to **Monitor > Routing Monitor**. In the CLI, use the `get router info routing-table all` command.

Static routing tips

When your network goes beyond basic static routing, here are some tips to help you plan and manage your static routing.

Always configure a default route

The first thing you configure on a router on your network should be the default route. And where possible, the default routes should point to either one or very few gateways. This makes it easier to locate and correct problems in the network. By comparison, if one router uses a second router as its gateway which uses a fourth for its gateway and so on, one failure in that chain will appear as an outage for all the devices downstream. By using one or very few addresses as gateways, if there's an outage on the network, it will either be very localized or network-wide. Either outage is easy to troubleshoot.

Have an updated network plan

A network plan lists different subnets, user groups, and different servers. Essentially, it puts all your resources on the network and shows how the parts of your network are connected. Keeping your plan updated will also help you troubleshoot problems more quickly when they arise.

A network plan helps your static routing by eliminating potential bottlenecks and helping troubleshoot any routing problems that come up. Also, you can use it to plan for the future and act on any changes to your needs or resources more quickly.

Plan for expansion

No network remains the same size. At some time, all networks grow. If you take future growth into account, there will be less disruption to your existing network when that growth happens. For example, allocating a block of addresses for servers can easily prevent having to re-assign IP addresses to multiple servers due to a new server.

With static routing, if you group parts of your network properly you can easily use network masks to address each part of your network separately. This will reduce the amount of administration required both to maintain the routing and to troubleshoot any problems.

Configure as much security as possible

Securing your network through static routing methods is a good low level method to defend both your important information and your network bandwidth.

- Implement NAT to obscure your IP address is an excellent first step
- Implement blackhole routing to hide which IP addresses are in use or not on your local network
- Configure and use access control list (ACL) to help ensure you know only valid users are using the network

All three features limit access to the people who should be using your network and obscure your network information from the outside world and potential hackers.

Policy routing

Policy routing allows you to redirect traffic away from a static route. This can be useful if you want to route certain types of network traffic differently. You can use incoming traffic's protocol, source address or interface, destination address, or port number to determine where to send the traffic. For example, generally network traffic

will go to the router of a subnet, but you might want to direct SMTP or POP3 traffic directly to the mail server on that subnet.

If you configure the FortiGate with routing policies and a packet arrives at the FortiGate, the FortiGate starts at the top of the Policy Route list and attempts to match the packet with a policy. If a match is found and the policy contains enough information to route the packet (a minimum of the IP address of the next-hop router and the FortiGate interface for forwarding packets to it), the FortiGate routes the packet using the information in the policy. If no policy route matches the packet, the FortiGate routes the packet using the routing table.

Most policy settings are optional, and a matching policy alone might not provide enough information for forwarding the packet. In fact, the FortiGate almost always requires a matching route in the routing table in order to use a policy route. The FortiGate refers to the routing table in an attempt to match the information in the packet header with a route in the routing table.

Policy route options define which attributes of an incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the FortiGate routes the packet through the specified interface to the specified gateway.

To view policy routes go to **Network > Policy Routes**.

Field	Description
Create New	Add a policy route. See "Adding a policy route" on page 2079 .
Edit	Edit the selected policy route.
Delete	Delete the selected policy route.
Move To	Move the selected policy route. Enter the new position and select OK . For more information, see "Moving a policy route" on page 2082 .
#	The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.
Incoming	The interfaces on which packets subjected to route policies are received.
Outgoing	The interfaces through which policy routed packets are routed.
Source	The IP source addresses and network masks that cause policy routing to occur.
Destination	The IP destination addresses and network masks that cause policy routing to occur.

Adding a policy route

To add a policy route, go to **Network > Policy Routes** and select **Create New**.

Field	Description
Protocol	<p>Select from existing or specify the protocol number to match. The Internet Protocol Number is found in the IP packet header. RFC 5237 describes protocol numbers and you can find a list of the assigned protocol numbers here. The range is from 0 to 255. A value of 0 disables the feature.</p> <p>Commonly used Protocol settings include 6 for TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions.</p>
Incoming Interface	Select the name of the interface through which incoming packets subjected to the policy are received.
Source Address / Mask	To perform policy routing based on IP source address, type the source address and network mask to match. A value of 0.0.0.0/0.0.0.0 disables the feature.
Destination Address / Mask	To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of 0.0.0.0/0.0.0.0 disables the feature.
Destination Ports	<p>To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature.</p> <p>The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.</p>
Type of Service	Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see "Type of service" on page 2081 .
Outgoing Interface	Select the name of the interface through which packets affected by the policy will be routed.
Gateway Address	Type the IP address of the next-hop router that the FortiGate can access through the specified interface.

Example policy route

Configure the following policy route to send all FTP traffic received at `port1` out the `port10` interface and to a next hop router at IP address `172.20.120.23`. To route FTP traffic, set protocol to 6 (for TCP) and set both of the destination ports to 21 (the FTP port).

Field	Value
Protocol	6

Field	Value
Incoming interface	port1
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0
Destination Ports	From 21 to 21
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)
Outgoing interface	port10
Gateway Address	172.20.120.23

Enabling or disabling individual policy routes

You can enable or disable individual policy routes.

To configure IPv4 policy routes - CLI:

```
config router policy
  edit <sequence number>
    set status {enable | disable}
  next
end
```

To configure IPv6 policy routes - CLI:

```
config router policy6
  edit <sequence number>
    set status {enable | disable}
  next
end
```

Type of service

Type of service (TOS) is an 8-bit field in the IP header that allows you to determine how the IP datagram should be delivered, with qualities, such as delay, priority, reliability, and minimum cost.

Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority TOS is 0, the highest is 7 - when bits 3, 4, and 5 are all set to 1. The router tries to match the TOS of the datagram to the TOS on one of the possible routes to the destination. If there's no match, the datagram is sent over a zero TOS route.

Using increased quality may increase the cost of delivery because better performance may consume limited network resources. For more information, see [RFC 791](#) and [RFC 1349](#).

The role of each bit in the IP header TOS 8-bit field

Bit	Quality	Description
bits 0, 1, 2	Precedence	Some networks treat high precedence traffic as more important traffic. Precedence should only be used within a network, and can be used differently in each network. Typically, you don't care about these bits.
bit 3	Delay	When set to 1, this bit indicates low delay is a priority. This is useful for such services as VoIP where delays degrade the quality of the sound.
bit 4	Throughput	When set to 1, this bit indicates high throughput is a priority. This is useful for services that require lots of bandwidth, such as video conferencing.
bit 5	Reliability	When set to 1, this bit indicates high reliability is a priority. This is useful when a service must always be available, such as with DNS servers.
bit 6	Cost	When set to 1, this bit indicates low cost is a priority. Generally there is a higher delivery cost associated with enabling bits 3, 4, or 5, and bit 6 indicates to use the lowest cost route.
bit 7	Reserved for future use	Not used at this time.

For example, if you want to assign low delay and high reliability for a VoIP application, where delays are unacceptable, you would use a bit pattern of xxx1x1xx where 'x' indicates that bit can be any value. Since all bits aren't set, this is a good use for the bit mask. If the mask is set to 0x14, it will match any TOS packets that are set to low delay and high reliability.

Moving a policy route

A routing policy is added to the bottom of the routing table when it's created. If you prefer to use one policy over another, you may want to move it to a different location in the routing policy table.

The option to use one of two routes happens when both routes are a match, for example 172.20.0.0/255.255.0.0 and 172.20.120.0/255.255.255.0. If both of these routes are in the policy table, both can match a route to 172.20.120.112 but you would consider the second one a better match. In this case, the best match route should be positioned before the other route in the policy table.

To change the position of a policy route in the table, go to **Network > Policy Routes** and select **Move To** for the policy route you want to move.

Field	Description
Before/After	Select Before to place the selected policy route before the indicated route. Select After to place it following the indicated route.
Policy route ID	Enter the policy route ID of the route in the policy route table to move the selected route before or after.

Use of firewall addresses for policy route destinations

When you configure a policy route, you can use firewall addresses and address groups. The only exception for the address types that can be used is the URL type of address object.

Static routing in transparent mode

FortiOS operating modes allow you to change the configuration of a FortiGate, depending on its role in your network. A FortiGate can operate in two different modes: transparent operation mode or NAT operation mode. In transparent mode, a FortiGate acts as a bridge where all physical interfaces act like one interface. A FortiGate broadcasts traffic that arrives through any interface out through all interfaces.

In transparent mode, you install a FortiGate between your internal network and your router. The FortiGate doesn't make any changes to IP addresses and applies only security scanning to traffic. When you add a FortiGate to a network in transparent mode, you don't have to make any network changes except configuring the FortiGate with a management IP address. You usually use transparent mode when you want to increase your network protection but it's impractical to change your network configuration.

When you configure routing in transparent mode on a FortiGate, all interfaces must be connected to the same subnet. This means all traffic comes from and leaves on the same subnet. This is important because it limits the static routing options to only gateways that are attached to this subnet. For example, if you have only one router that connects your network to the Internet, all static routing on the FortiGate uses this gateway. For this reason, static routing on a FortiGate in transparent mode may be a bit different, but it's not as complex as routing in NAT mode.

To view the routing table in transparent mode, go to **Network > Static Routes**. When you view entries for static routes in transparent mode, you'll see the following settings:

Field	Description
Destination	When Subnet is selected, shows the IP address and netmask of the destination of the traffic being routed. 0.0.0.0 is the default route and matches all traffic destinations.
Gateway	Specifies the IP address of the next hop for traffic. This is usually the IP address of a router on the edge of your network.
Priority	<p>The FortiGate uses the priority if there's more than one match for a route. This allows you to use multiple routes, but configure preferred routes.</p> <p>Routes with a larger value have a lower priority. If the preferred route isn't available, another route is used instead. If there is more than one match for a route, and the routes have the same priority, the FortiGate uses Equal Cost Multiple Path (ECMP) to share traffic between the routes.</p> <p>The possible values are 0 to 4294967295. This setting only applies to static routes. The priority for routes that are dynamically learned from routing protocols is 0.</p>

For more information about configuring a FortiGate in transparent mode, see the [FortiOS Transparent Mode Handbook](#).

Source prefixes for static routes in transparent mode

If a FortiGate has more than one management IP address and default route, packets can't differentiate between them and may reach the wrong management IP address. To avoid this, you can configure a source prefix that allows the FortiGate to differentiate between multiple default routes. This is necessary only for static routes in transparent mode.

To configure source prefixes - CLI:

```
config router static
  edit <sequence-number>
    set gateway <IP-address>
    set src <source-prefix>
  next
  edit <sequence-number>
    set gateway <IP-address>
    set src <source-prefix>
  next
end
```

This command is only available in transparent mode.

Static routing example

This is an example of a typical small network configuration that uses only static routing.

This network is in a dental office that includes a number of dentists, assistants, and office staff. The size of the office isn't expected to grow significantly in the near future, and the network usage is very stable (there are no new applications being added to the network).

The users on the network are:

- Administrative staff: Access to local patient records to perform online billing
- Dentists: Access and update local patient records to research online from desk
- Assistants: Access and update local patient records in exam rooms

The distinction here is mainly that only the administrative staff and dental office need access to the Internet. All other traffic is local and doesn't need to leave the local network. Routing is only required for the outbound traffic and the computers that have valid outbound traffic.

Configuring routing only on computers that need it acts as an additional layer of security by helping prevent malicious traffic from leaving the network.

Network layout and assumptions

The computers on the network are administrative staff computers, dental office computers, and dental exam room computers. While there are other devices on the local network, such as printers, they don't need Internet access or any routing.

The networked office equipment includes one PC for administrative staff, 3 PCs for dentists, and 5 PCs in the exam rooms. There's also a network printer and a router on the network.

Assumptions about these computers and network include:

- The FortiGate is a model with interfaces labeled port1 and port2.
- The FortiGate has been installed and is configured in NAT/Route mode.
- VDOMs aren't enabled.
- The computers on the network are running MS Windows software.
- Any hubs required in the network aren't shown in the network diagram.
- The network administrator has access to the ISP IP addresses and is the super_admin administrator on the FortiGate.

Static routing example device names, IP addresses, and level of access

Device name	IP address	Need external access?
Router	192.168.10.1	Yes
Admin	192.168.10.11	Yes
Dentist1-3	192.168.10.21-23	Yes
Exam1-5	192.168.10.31-35	No
Printer	192.168.10.41	No

General configuration steps

The steps to configuring routing on this network are:

1. [Get your ISP information such as DNS, gateway, etc.](#)
2. [Configure the FortiGate](#)
3. [Configure the PCs for the administrator and dentists](#)
4. [Testing network configuration](#)

Get your ISP information such as DNS, gateway, etc.

Your local network connects to the Internet through your Internet Service Provider (ISP). They have IP addresses that you need to configure your network and routing.

The addresses that you need for routing are your assigned IP address, DNS servers, and the gateway.

Configure the FortiGate

The FortiGate has two interfaces in use: one connected to the internal network and one connected to the external network. Port1 is the internal interface and port2 is the external interface.

To configure the FortiGate:

1. [Configure the internal interface \(port1\)](#)
2. [Configure the external interface \(port2\)](#)
3. [Configure networking information](#)

4. [Configure basic security policies](#)
5. [Configure static routing](#)

Configure the internal interface (port1)

To configure the internal interface (port1) - GUI:

1. Go to **Network > Interfaces**. Highlight **port1** and select **Edit**.
2. Enter the following information:

Addressing Mode	Manual
IP/Netmask	172.100.1.1/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port1) - CLI:

```
config system interface
  edit port1
    set IP 192.168.10.1 255.255.255.0
    set allowaccess https ping telnet
    set description "internal network"
  next
end
```

Configure the external interface (port2)

The external interface connects to your ISP network. You need to know the IP addresses in their network that you should connect to. In this example, the address that the ISP gave you is 172.100.20.20, which will connect to the gateway at 172.100.20.5 on their network, and their DNS servers are 172.11.22.33 and 172.11.22.34.

To configure the internal interface (port2) - GUI:

1. Go to **Network > Interfaces**. Highlight **port2** and select **Edit**.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.20.20/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port2) - CLI:

```
configure system interface
  edit port2
    set IP 172.100.20.20 255.255.255.0
    set allowaccess https ping telnet
```

```
        set description "internal network"
    next
end
```

Configure networking information

Networking information includes the gateway and DNS servers. A FortiGate requires a connection to the Internet for antivirus and other periodic updates.

To configure networking information - GUI:

1. Go to **Network > DNS**.
2. Enter the primary and secondary DNS addresses.
3. Select **Apply**.

To configure networking information - CLI:

```
config system global
    set dns_1 172.11.22.33
    set dns_2 172.11.22.34
end
```

Configure basic security policies

For traffic to flow between the internal and external ports in both directions, as a minimum, two security policies are required. More can be used to further limit or direct traffic, as needed, but won't be included here.

Before configuring the security policies, a firewall address group is configured for the PCs that are allowed Internet access. This prevents a PC without Internet privileges from accessing the Internet.

The security policy assumptions are:

- For added security, only the basic networking services are listed as allowed. Others can easily be added as users require them.
- In this example, to keep things simple, both incoming and outgoing security policies are the same. In a real network there are applications that are allowed out but not in, and vice versa.
- Endpoint control has been enabled to ensure that all computers on the local network are running FortiClient and those installs are up to date. This feature ensures added security on your local network without the need for the network administrator to continually bother users to update their software. The FortiGate can store an up to date copy of the FortiClient software and offer a URL to it for users to install it if they need to.

To configure security policies - GUI:

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create a new Firewall Address entry for each of:

PC Name	IP Address	Interface
Admin	192.168.10.11	port1
Dentist1	192.168.10.21	port1

Dentist2	192.168.10.22	port1
Dentist3	192.168.10.23	port1

3. Go to **Policy & Objects > Objects > Addresses**.
4. Select the dropdown arrow next to **Create New** and select **Address Group**.
5. Name the group Internet_PCs.
6. Add Admin, Dentist1, Dentist2, and Dentist3 as members of the group.
7. Select **OK**.
8. Go to **Policy & Objects > Policy > IPv4**.
9. Select **Create New**.
10. Enter the following: DH - port2(external) -> port1(internal)

Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	Internet_PCs
Schedule	always
Service	Multiple. Select DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.
Action	ACCEPT
Log Allowed Traffic	Enabled

11. Select **OK**.
12. Select **Create New**.
13. Enter the following:

Incoming Interface	port1
Source Address	Internet_PCs
Outgoing Interface	port2
Destination Address	all
Schedule	always

Service	Multiple. Select DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.
Action	ACCEPT
Log Allowed Traffic	Enabled

14. Select **OK**.

To configure security policies - CLI:

```
config firewall address
  edit "Admin"
    set associated-interface "port1"
    set subnet 192.168.10.11 255.255.255.255
  next
  edit "Dentist1"
    set associated-interface "port1"
    set subnet 192.168.10.21 255.255.255.255
  next
  edit "Dentist2"
    set associated-interface "port1"
    set subnet 192.168.10.22 255.255.255.255
  next
  edit "Dentist3"
    set associated-interface "port1"
    set subnet 192.168.10.23 255.255.255.255
  end
config firewall addrgrp
  edit Internet_PCs
    set member Admin Dentist1 Dentist2 Dentist3
  end
config firewall policy
  edit 1
    set srcintf port1
    set dstintf port2
    set srcaddr Internet_PCs
    set dstaddr all
    set action accept
    set schedule always
    set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
    set logtraffic enable
    set label "Section2"
    set endpoint-restrict-check no-av db-outdated
  next
  edit 2
    set srcintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr Internet_PCs
    set action accept
    set schedule always
    set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3" "SMTP" "SSH"
    set logtraffic enable
```

```

        set label "Section2"
        set endpoint-restrict-check no-av db-outdated
    next
end

```

Adding FortiClient enforcement to interfaces

You can enforce the use of FortiClient on individual interfaces.

In the FortiGate GUI, select **Network > Interfaces** and choose an interface. Under the **Admission Control** heading, you can enable the **Allow FortiClient Connections** setting. Once you enable this setting, two more options become visible: **Discover Clients (Broadcast)** and **FortiClient Enforcement**. When you enable FortiClient enforcement, you enforce that in order for incoming traffic to pass through that interface, it must be initiated by a device running FortiClient.

Once you enforce the use of FortiClient on the interface, you should also configure FortiClient profiles for the incoming connections. You can also set up any exemptions that are needed. Just below the **FortiClient Enforcement** option are fields for **Exempt Sources** and **Exempt Destinations/Services**. These can be selected from address or services objects already configured on the FortiGate.

In the CLI, use the following commands:

```

config system interface
    edit port1
        set listen-forticlient-connection [enable|disable]
        set endpoint-compliance [enable|disable]
    next
end

```

Configure static routing

With the rest of the FortiGate configured, static routing is the last step before moving on to the rest of the local network. All traffic on the local network will be routed according to this static routing entry.

To configure Fortinet static routing - GUI:

1. Go to **Network > Static Routes**.
2. Select the top route on the page and then select **Edit**.
3. Enter the following information:

Destination IP/Mask	172.100.20.5
Gateway	172.100.20.5
Interface	port2
Administrative Distance	10

4. Select **OK**.

To configure Fortinet unit static routing - CLI:

```

configure routing static
    edit 1

```

```
set gateway 172.100.20.5
set distance 10
set device port2
set dst 0.0.0.0
next
end
```

Configure the PCs for the administrator and dentists

After the router is configured, we need to configure the computers that require Internet access. These computers need routing to be configured on them. As the other computers don't require routing, they aren't included here.

The procedure to configure these computers is the same. Repeat the following procedure for the corresponding PCs.

The Windows CLI procedure doesn't configure the DNS entries. It just adds the static routes.

To configure routing and DNS on PCs for administrator and dentists - Windows GUI:

1. On the PC, select **Start > Control Panel > Network Connections**.
2. Right click on the network connection to your local network that has a status of Connected, and select **Properties**.
3. Under the **General** tab, from the list select **TCP/IP**, and **Properties**.
4. Under **Gateway**, enter the FortiGate unit address (192.168.10.1).
5. Enter the primary and secondary DNS server addresses from your ISP (172.11.22.33 and 172.11.22.34).
6. Select **OK**.

To configure routing on PCs for administrator and dentists - Windows CLI:

1. On the PC, select **Start > Run**, enter "cmd", and select **OK**.
2. At the command prompt, type:

```
route ADD 0.0.0.0 MASK 0.0.0.0 172.100.20.5 METRIC 10
route ADD 192.168.10.0 MASK 255.255.255.0 192.168.10.1 METRIC 5
```
3. Confirm these routes have been added. Type:

```
route PRINT
```

If you don't see the two routes you added, try adding them again, while paying attention to avoid spelling mistakes.
4. Test that you can communicate with other computers on the local network, and with the Internet. If there are no other computers on the local network, connect to the FortiGate.

Configure other PCs on the local network

The PCs on the local network without Internet access (for example, the exam room PCs) can be configured now.

As this step doesn't require any routing, details haven't been included.

Testing network configuration

There are three tests that you can run on the network to ensure proper connectivity:

- Test that PCs on the local network can communicate
- Test that Internet_PCs on the local network can access the Internet
- Test that non-Internet_PCs can't access the Internet

Test that PCs on the local network can communicate

1. Select any two PCs on the local network, such as Exam4 and Dentist3.
2. On the Exam4 PC, at the command prompt, enter `ping 192.168.10.23`.

The output from this command should appear similar to the following:

```
Pinging 192.168.10.23 with 32 bytes of data:
```

```
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

3. At the command prompt, enter `exit` to close the window.
4. On the Dentist3 PC, at the command prompt, enter `ping 192.168.10.34`.

The output from this command should appear similar to the following:

```
Pinging 192.168.10.34 with 32 bytes of data:
```

```
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

5. At the command prompt, enter `exit` to close the window.
6. Repeat these steps for all PCs on the local network.

If the output doesn't appear similar to above, there's a problem with the network configuration between these two PCs.

To test that Internet_PCs on the local network can access the Internet

The easiest way to access the Internet is with an Internet browser. However, if that doesn't work, it's best to do a traceroute to see at what point the problem is. This can help determine if it's a networking problem, such as cabling, or if it's an access problem, such as this PC not having Internet access.

1. Select any PC on the local network that's supposed to have Internet access, such as Admin.
2. On the Admin PC, open an Internet browser and attempt to access a website on the Internet, such as <http://www.fortinet.com>.

If this is successful, this PC has Internet access.

3. If step2 wasn't successful, at the command prompt on the PC, enter `tracert 22.11.22.33`.

The output from this command should appear similar to:

```
Pinging 22.11.22.33 with 32 bytes of data:
```

```
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

Dynamic routing

Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. Instead of having to manually enter static routes in the routing table, dynamic routing automatically receives routing updates and dynamically decides which routes are best to go into the routing table. It's this intelligent and hands-off approach that makes dynamic routing so useful.

Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors. For more information about these administrative distances, see ["Advanced static routing" on page 2062](#).

Overview

Comparing static and dynamic routing

A common term used to describe dynamic routing is convergence. Convergence is the ability to work around network problems and outages, for the routing to come together despite obstacles. For example, if the main router between two endpoints goes down, convergence is the ability to find a way around that failed router and reach the destination. Static routing has zero convergence beyond trying the next route in its limited local routing table. If a network administrator doesn't fix a routing problem manually, it may never be fixed and may result in a downed network. Dynamic routing solves this problem by involving routers along the route in the decision-making process about the optimal route, and using the routing tables of these routers to find potential routes around the outage. In general, dynamic routing has better scalability, robustness, and convergence. However, the cost of these added benefits includes more complexity and some overhead. For example, the routing protocol uses some bandwidth for its own administration.

Comparing static and dynamic routing

Feature	Static routing	Dynamic routing
Hardware support	Supported by all routing hardware	May require special, more expensive routers
Router memory required	Minimal	Can require considerable memory for larger tables
Complexity	Simple	Complex
Overhead	None	Varying amounts of bandwidth used for routing protocol updates
Scalability	Limited to small networks	Very scalable, better for larger networks
Robustness	None: if a route fails, it has to be fixed manually	Robust: traffic routed around failures automatically

Feature	Static routing	Dynamic routing
Convergence	None	Varies from good to excellent

Dynamic routing protocols

A dynamic routing protocol is an agreed-on method of routing that the sender, receiver, and all routers along the path (route), support. Typically, the routing protocol involves a process running on all computers and routers along that route to enable each router to handle routes in the same way as the others. The routing protocol determines how the routing tables are populated along that route, how the data is formatted for transmission, and what information about a route is included with that route. For example, RIP and BGP use distance vector algorithms and OSPF uses a shortest path first algorithm. Each routing protocol has different strengths and weaknesses. One protocol may have fast convergence, while another may be very reliable, and a third may be very popular for certain businesses like Internet Service Providers (ISPs).

Dynamic routing protocols are different from each other in a number of ways, such as:

- [Classful versus classless routing protocols](#)
- [Interior versus exterior routing protocols](#)
- [Distance vector versus link-state protocols](#)

Classful versus classless routing protocols

Classful and classless routing refers to how the routing protocol handles the IP addresses. In classful addresses, there's the specific address and the host address of the server that address is connected to. Classless addresses use a combination of IP address and netmask.

Classless Inter-Domain Routing (CIDR) was introduced in 1993 (originally with [RFC 1519](#) and most recently with [RFC 4632](#)) to keep routing tables from getting too large. With classful routing, each IP address requires its own entry in the routing table. With classless routing, a series of addresses can be combined into one entry, potentially saving vast amounts of space in routing tables.

Current routing protocols that support classless routing, out of necessity, include RIPv2, BGP, IS-IS, and OSPF. Older protocols, such as RIPv1, do not support CIDR addresses.

Interior versus exterior routing protocols

The names interior and exterior are very descriptive. Interior routing protocols are designed for use within a contained network of limited size, whereas exterior routing protocols are designed to link multiple networks together. They can be used in combination in order to simplify network administration. For example, a network can be built with only border routers of a network running the exterior routing protocol, while all the routers on the network run the interior protocol. This prevents them from connecting outside the network without passing through the border. Exterior routers in such a configuration must have both exterior and interior protocols to communicate with the interior routers and outside the network.

Nearly all routing protocols are interior routing protocols. Only BGP is commonly used as an exterior routing protocol.

You may see interior gateway protocol (IGP) used to refer to interior routing protocols and exterior gateway protocol (EGP) used to refer to exterior routing protocols.

Distance vector versus link-state protocols

Every routing protocol determines the best route between two addresses using a different method. However, there are two main algorithms for determining the best route: distance vector and link-state.

Distance vector protocols

In distance vector protocols, routers are told about remote networks through neighboring routers. The distance part refers to the number of hops to the destination and, in more advanced routing protocols, these hops can be weighted by factors such as available bandwidth and delay. The vector part determines which router is the next step along the path for this route. This information is passed along from neighboring routers with routing update packets that keep the routing tables up to date. Using this method, an outage along a route is reported back along to the start of that route, ideally before the outage is encountered.

On distance vector protocols, [RFC 1058](#), which defines RIP v1, states the following:

Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.

There are four main weaknesses inherent in the distance vector method. Firstly, the routing information isn't discovered by the router itself, but is instead reported information that must be relied on to be accurate and up-to-date. The second weakness is that it can take a while for the information to make its way to all the routers who need the information; in other words, it can have slow convergence. The third weakness is the amount of overhead involved in passing these updates all the time. The number of updates between routers in a larger network can significantly reduce the available bandwidth. The fourth weakness is that distance vector protocols can end up with routing-loops. Routing loops are when packets are routed forever around a network, and often occur with slow convergence. The bandwidth required by these infinite loops will slow your network to a halt. There are methods of preventing these loops, however, so this weakness isn't as serious as it may first appear.

Link-state protocols

Link-state protocols are also known as shortest path first protocols. Where distance vector uses information passed along that may or may not be current and accurate, in link-state protocols each router passes along information only about the networks and devices that are directly connected to it. This results in a more accurate picture of the network topology around your router, allowing it to make better routing decisions. This information is passed between routers using link-state advertisements (LSAs). To reduce the overhead, LSAs are only sent out when information changes, compared to distance vector sending updates at regular intervals even if no information has changed. The more accurate network picture in link-state protocols greatly speed up convergence and avoid problems such as routing-loops.

Minimum configuration for dynamic routing

Dynamic routing protocols don't pay attention to routing updates from other sources, unless you specifically configure them to do so using CLI redistribute commands within each routing protocol.

The minimum configuration for any dynamic routing to function is to have dynamic routing configured on one interface on a FortiGate, and one other router configured as well. Some protocols require larger networks to function as designed.

Minimum configuration based on dynamic protocol

	BGP	RIP	OSPF / IS-IS
Interface	Yes	Yes	Yes
Network	Yes	Yes	Yes
AS	Local and neighbor	No	Yes
Neighbors	At least one	At least one	At least one
Version	No	Yes	No
Router ID	No	No	Yes

Comparison of dynamic routing protocols

Each dynamic routing protocol was designed to meet a specific routing need. Each protocol does some things well and other things not so well. For this reason, choosing the right dynamic routing protocol for your situation isn't an easy task.

Features of dynamic routing protocols

Each protocol is better suited for some situations over others.

Choosing the best dynamic routing protocol depends on the size of your network, speed of convergence required, the level of network maintenance resources available, what protocols the networks you connect to are using, and so on. For more information about these dynamic routing protocols, see ["RIP" on page 2110](#), ["BGP" on page 2187](#), ["OSPF" on page 2146](#), and ["IS-IS" on page 2224](#).

Comparing RIP, BGP, and OSPF dynamic routing protocols

Protocol	RIP	BGP	OSPF / IS-IS
Routing algorithm	Distance vector, basic	Distance vector, advanced	Link-state
Common uses	Small, non-complex networks	Network backbone, ties multinational offices together	Common in large, complex enterprise networks

Protocol	RIP	BGP	OSPF / IS-IS
Strengths	Fast and simple to implement	Graceful restart	Fast convergence
	Near universal support	BFD support	Robust
	Good when no redundant paths	Only needed on border routers	Little management overhead
		Summarize routes	No hop count limitation
			Scalable
Weakness	Frequent updates can flood network	Required full mesh in large networks can cause floods	Complex
	Slow convergence	Route flap	No support for unequal cost multipath routing
	Maximum 15 hops may limit network configuration	Load-balance multi-homed networks	Route summary can require network changes
		Not available on low-end routers	
Authentication	Optional authentication using text string or MD5 password. (RIP v1 has no authentication)		
IPv6 support	Only in RIPng	Only in BGP4+	Only in OSPF6 / Integrated IS-IS

Routing protocols

- Routing Information Protocol (RIP) uses classful routing, as well as incorporating various methods to stop incorrect route information from propagating, such as the poisoned horizon method. However, on larger networks its frequent updates can flood the network and its slow convergence can be a problem.
- Border Gateway Protocol (BGP) has been the core Internet backbone routing protocol since the mid-1990s, and is the most used interior gateway protocol (IGP). However, some configurations require full mesh connections which flood the network, and there can be route flap and load balancing issues for multihomed networks.
- Open Shortest Path First (OSPF) is commonly used in large enterprise networks. It is the protocol of choice, mainly due to its fast convergence. However, it can be complicated to setup properly.
- Intermediate System to Intermediate System (IS-IS) protocol allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) that's not intended to be used between Autonomous Systems (ASes). IS-IS is a link state protocol well-suited to smaller networks that's in widespread use and has near universal support on routing hardware.
- Multicast addressing is used to broadcast from one source to many destinations efficiently. Protocol Independent Multicast (PIM) is the protocol commonly used in enterprises, multimedia content delivery, and stock exchanges.

Routing algorithm

Each protocol uses a slightly different algorithm for choosing the best route between two addresses on the network. The algorithm is the intelligent part of a dynamic protocol because the algorithm is responsible for deciding which route is best and should be added to the local routing table. RIP and BGP use distance vector algorithms, where OSPF and IS-IS use link-state or a shortest path first algorithm.

Vector algorithms are essentially based on the number of hops between the originator and the destination in a route, possibly weighting hops based on how reliable, fast, and error-free they are.

The link-state algorithm used by OSPF and IS-IS is called the Dijkstra algorithm. Link-state treats each interface as a link and records information about the state of the interface. The Dijkstra algorithm creates trees to find the shortest paths to the routes it needs based on the total cost of the parts of the routes in the tree.

For more information about the routing algorithm used, see ["Distance vector versus link-state protocols" on page 2095](#).

Authentication

If an attacker gains access to your network, they can masquerade as a router on your network to either gain information about your network or disrupt network traffic. If you have a high quality firewall configured, it will help your network security and stop many of these types of threats. However, the main method for protecting your routing information is to use authentication in your routing protocol. Using authentication on a FortiGate and other routers, prevents access by attackers because all routers must authenticate with passwords, such as MD5 hash passwords, to ensure they are legitimate routers.

When you configure authentication on your network, ensure that you configure it the same way on all devices on the network. Failure to do so will create errors and outages as those forgotten devices fail to connect to the rest of the network.

For example, to configure an MD5 key of 123 on an OSPF interface called `ospf_test`, enter the following CLI commands:

```
config router ospf
  config ospf-interface
    edit ospf_test
      set authentication md5
      set md5-key 123
    next
  end
```

Convergence

Convergence is the ability of a networking protocol to re-route around network outages. Static routing can't do this. Dynamic routing protocols can all converge, but take various amounts of time to do this. Slow convergence can cause problems, such as network loops, which degrade network performance.

You may also hear robustness and redundancy used to describe networking protocols. In many ways, they're the same thing as convergence. Robustness is the ability to keep working even though there are problems, including configuration problems as well as network outages. Redundancy involves having duplicate parts that can continue to function in the event of some malfunction, error, or outage. It's relatively easy to configure dynamic routing protocols to have backup routers and configurations that will continue to function no matter what the network problem is, short of a total network failure.

IPv6 support

IPv4 addressing is in common use everywhere around the world. IPv6 has much larger addresses and it's used by many large companies and government departments. IPv6 isn't as common as IPv4 yet, but more companies are adopting it.

If your network uses IPv6, your dynamic routing protocol must support it. None of the dynamic routing protocols supported IPv6 originally, but they all have additions, expansions, or new versions that now support IPv6. For more information, see ["RIP" on page 2110](#), ["BGP" on page 2187](#), ["OSPF" on page 2146](#), and ["IS-IS" on page 2224](#).

When to adopt dynamic routing

Static routing is more than enough to meet your networking needs when you have a small network. However, as your network grows, the question you need to answer is at what point do you adopt dynamic routing in your networking plan and start using it in your network? The main factors in this decision are typically budget, current network size and topology, expected network growth, and available resources for ongoing maintenance.

Budget

When making any business decision, you must always consider your budget. Static routing doesn't involve special hardware, fancy software, or expensive training courses.

Dynamic routing can include all of these extra expenses. Any new hardware, such as routers and switches, need to support the routing protocols that you choose. Network management software and routing protocol drivers may also be necessary to help configure and maintain your more complex network. If the network administrators are not well versed in dynamic routing, you must budget either a training course or some hands-on learning time so they can administer the new network with confidence. Together, these factors can impact your budget.

Additionally, people will always account for network starting costs in the budgets but usually leave out the ongoing cost of network maintenance. Any budget must provide for the hours that will be spent on updating the network routing equipment and fixing any problems. Without that money in the budget, you may end up back at static routing before you know it.

Current network size and topology

As stated earlier, static routing works well on small networks. As those networks get larger, routing takes longer, routing tables get very large, and general performance isn't what it could be.

Topology is a concern as well. If all your computers are in one building, it is much easier to stay with static routing longer. However, connecting a number of locations will be easier with the move to dynamic routing.

If you have a network of 20 computers, you can still likely use static routing. If those computers are in two or three locations, static routing will still be a good choice for connecting them. Also, if you just connect to your ISP and don't worry about any special routing to do that, you're likely safe with just static routing.

If you have a network of 100 computers in one location, you can use static routing but it will be slower, more complex, and there won't be much room for expansion. If those 100 computers are spread across three or more locations, dynamic routing is the way to go.

If you have 1000 computers, you definitely need to use dynamic routing no matter how many locations you have.

Hopefully this section has given you an idea of what results you'll likely experience from different sized networks using different routing protocols. Your choice of which dynamic routing protocol to use is partly determined by the network size and topology.

Expected network growth

You may not be sure if your current network is ready for dynamic routing. However, if you're expecting rapid growth in the near future, it's a good idea to start planning for that growth now so you're ready for the coming expansion.

Static routing is very labor intensive. Each network device's routing table needs to be configured and maintained manually. If there's a large number of new computers being added to the network, they each need to have the static routing table configured and maintained. If devices are being moved around the network frequently, they must also be updated each time.

Instead, consider putting dynamic routing in place before the new computers are installed on the network. The installation issues can be worked out with a smaller and less complex network, and when the new computers or routers are added to the network there will be nowhere near the level of manual configuration required. Depending on the level of growth, the labor savings can be significant. For example, in an emergency you can drop a new router into a network or AS, wait for it to receive the routing updates from its neighbors, and then remove one of the neighbors. While the routes will not be the most effective possible, this method is much less work than static routing in the same situation, with less chance of mistakes.

Also, as your network grows and you add more routers, the new routers can help share the load in most dynamic routing configurations. For example, if you have 4 OSPF routers and 20,000 external routes, those few routers will be overwhelmed. But a network with 15 OSPF routers will be better able to handle that number of routes. However, be aware that adding more routers to your network will increase the amount of updates sent between the routers, which will use up a greater part of your bandwidth and use more bandwidth overall.

Available resources for ongoing maintenance

As explained in the budget section, there must be resources dedicated to ongoing network maintenance, upgrades, and troubleshooting. These resources include administrator hours to configure and maintain the network, training for the administrator (if needed), extra hardware and software as needed, and possible extra staff to help the administrator in emergencies. Without these resources, you'll quickly find the network reverting to static routing out of necessity. This is because:

- Routing software updates require time
- Routing hardware updates require time
- Office reorganizations or significant personnel movement require time from a networking point of view
- Networking problems that occur, such as failed hardware, require time to locate and fix the problem

If resources to accomplish these tasks are not budgeted, the tasks will either not happen at the required level to continue operation or not happen at all. This will result in both the network administration staff and the network users being very frustrated.

A lack of a maintenance budget will also result in an increasingly heavy reliance on static routing as the network administrators are forced to use quick fixes for problems that come up. This invariably involves going to static routing, and dropping the more complex and time-consuming dynamic routing.

Choosing a routing protocol

One of the hardest decisions in routing can be choosing which routing protocol to use on your network. It can be easy to decide when static routing won't meet your needs, but how can you tell which dynamic routing protocol is best for your network and situation?

Here's a brief look at the routing protocols, including their strongest and weakest points. The steps to choosing your routing protocol are:

1. [Answer questions about your network](#)
2. [Evaluate your chosen protocol](#)
3. [Implement your dynamic routing protocol](#)

Answer questions about your network

Before you can decide what is best for your situation, you need to examine the details of your situation, such as what your budget, equipment, and users are.

The following questions will help you form a clear idea of your routing needs:

How many computers or devices are on your network?

The number of computers or devices that you have on your network, and whether the devices are all in one location or distributed, matters. All routing protocols can be run on networks of any size, but it can be inefficient to run some routing protocols on very small networks. Also, routers and network hardware that support dynamic routing can be more expensive than more generic routers for static routing.

What applications typically run over the network?

Finding out what applications your users are running will help you determine their needs and the needs of the network regarding bandwidth, quality of service, and other such issues.

What level of service do the users expect from the network?

Different users have different expectations of the network. It's not critical for someone surfing the Internet to have 100% uptime, but it's required for a stock exchange network or a hospital.

Is there network expansion in your near future?

You may have a small network now, but if it will be growing quickly, you should plan for the expected size so you don't have to change technologies again down the road.

What routing protocols do your networks connect to?

This is most often how routing protocol decisions are made. You need to be able to communicate easily with your service provider and neighbors, so often people simply use what everyone else is using.

Is security a major concern?

Some routing protocols have levels of authentication and other security features built in, and others do not. If security is important to you, be aware of this.

What is your budget?

You need to know what both your initial and maintenance budget is. More robust and feature-laden routing protocols generally mean more resources are required to keep them working well. Also, more secure configurations require still more resources. This includes both set up costs and ongoing maintenance costs. If you ignore these costs, you risk having to drop the adoption of the new routing protocol mid-change.

Evaluate your chosen protocol

Once you've examined the features of the routing protocols listed above and chosen the one that best meets your needs, you can set up an evaluation or test installation of that protocol.

The test installation is generally set up in a sandbox configuration so it won't affect critical network traffic. The aim of the test installation is to prove that it will work on a larger scale on your network. You must ensure that the test installation mirrors your larger network well enough for you to discover any problems. If the test installation is too simple, these problems may not appear.

If your chosen protocol does not meet your goals, choose a different protocol and repeat the evaluation process until a protocol meets your needs or you change your criteria.

Implement your dynamic routing protocol

You've examined your needs, selected the best matching dynamic routing protocol, tested it, and now you're ready to implement it with confidence.

This guide will help you configure a FortiGate to support your chosen dynamic routing protocol. Refer to the various sections in this guide, as needed, during your implementation to help ensure a smooth transition. Examples for each protocol are included to show proper configurations for different types of networks.

Dynamic routing terminology

Dynamic routing is a complex subject. There are many routers on different networks and all of them can be configured differently. It's more complicated by the fact that each routing protocol has different names for similar features, as well as many features that you can configure for each protocol.

To better understand dynamic routing, the following sections provide explanations on common dynamic routing terms.

For more details about a term, as it applies to a dynamic routing protocol, see ["BGP" on page 2187](#), ["RIP" on page 2110](#), and ["OSPF" on page 2146](#).

Aggregated routes and addresses

Just as an aggregate interface combines multiple interfaces into one virtual interface, an aggregate route combines multiple routes into one route. This reduces the amount of space those routes require in the routing tables of the routers along that route. The trade-off is a small amount of processing to aggregate and de-aggregate the routes at either end.

The benefit of this method is that you can combine many addresses into one, potentially reducing the routing table size immensely. The weakness of this method is if there are holes in the address range you are aggregating, you need to decide if it is better to break it into multiple ranges, or accept the possibility of failed routes to the missing addresses.

For information about aggregated routes in BGP, see ["BGP" on page 2187](#).

To manually aggregate the range of IP addresses from 192.168.1.100 to 192.168.1.103:

1. Convert the addresses to binary:

```
192.168.1.100 = 11000000 10101000 00000001 01100100
192.168.1.101 = 11000000 10101000 00000001 01100101
192.168.1.102 = 11000000 10101000 00000001 01100110
192.168.1.103 = 11000000 10101000 00000001 01100111
```

2. Determine the maximum number of matching bits common to the addresses.

There are 30 bits in common, with only the last 2 bits being different.

3. Record the common part of the address:

```
11000000 10101000 00000001 0110010X = 192.168.1.100
```

4. For the netmask, assume all the bits in the netmask are 1, except those that are different (which are 0):

```
11111111 11111111 11111111 11111100 = 255.255.255.252
```

5. Combine the common address bits and the netmask:

```
192.168.1.100/255.255.255.252
```

Alternately, the IP mask may be written as a single number:

```
192.168.1.100/2
```

6. As required, set variables and attributes to declare that the routes have been aggregated, and which router did the aggregating.

Autonomous system

An Autonomous System (AS) is one or more connected networks that use the same routing protocol, and appear to be a single unit to any externally connected networks. For example, an ISP may have a number of customer networks connected to it, but to any networks connected externally to the ISP, it appears as one system or AS. An AS may also be referred to as a routing domain.

It should be noted that while OSPF routing takes place within one AS, the only part of OSPF that deals with the AS is the AS border router (ASBR).

There are multiple types of ASs, which are defined by how they are connected to other ASs. A multihomed AS is connected to at least two other ASs and has the benefit of redundancy. If one of those ASs goes down, your AS can still reach the Internet through its other connection. A stub AS has only one connection and can be useful in specific configurations where limited access is desirable.

Each AS has a number assigned to it, known as an ASN. In an internal network, you can assign any ASN you like (a private AS number), but for networks connected to the Internet (public AS), you need to have an officially registered ASN from the Internet Assigned Numbers Authority (IANA). ASNs from 1 to 64,511 are designated for public use.

NAs of January 2010, AS numbers are 4 bytes long, instead of the former 2 bytes. [RFC 4893](#) introduced 32-bit ASNs, which FortiGate support for BGP and OSPF.

Do you need your own AS?

The main factors in deciding if you need your own AS, or if you should be part of someone else's are:

- Exchanging external routing information
- Many prefixes should exist in one AS as long as they use the same routing policy
- When you use a different routing protocol than your border gateway peers. For example, your ISP uses BGP and you use OSPF.
- Connected to many other ASs (multihomed)

You shouldn't create an AS for each prefix on your network. You also shouldn't be forced into an AS just so someone else can make AS-based policy decisions on your traffic.

There can be only one AS for any prefix on the Internet. This is to prevent routing issues.

What AS number should you use?

In addition to overseeing IP address allocation and Domain Name Systems (DNS), the Internet Assigned Numbers Authority (IANA) assigns public AS numbers. The public AS numbers range from 1 to 64,511. The ASNs 0, 54272 to 64511, and 65535 are reserved by the IANA and shouldn't be used.

ASNs are assigned in blocks by the Internet Assigned Numbers Authority (IANA) to Regional Internet Registries (RIR), who then assign ASNs to companies within the geographic area of the RIR. These companies are usually ISPs, and to receive an ASN you must complete the application process of the local RIR and be approved before being assigned an ASN. The following table shows the names and regions of the RIRs:

AFRINIC	Serves the African continent
APNIC	Asia-Pacific, including China, India, and Japan
ARIN	American registry, including Canada and United States
LACNIC	Latin America, including Mexico, Caribbean, Central and South America
RIPE NCC	Europe, the Middle East, the former USSR, and parts of Central Asia

AS numbers from 64512 to 65534 are reserved for private use. Private AS numbers can be used for any internal networks with no outside connections to the Internet, such as test networks, classroom labs, and other internal-only networks that don't access the outside world. You can also configure border routers to filter out any private ASNs before routing traffic to the outside world. If you must use private ASNs with public networks, this is the only way to configure them. However, it's risky because many other private networks could be using the same ASNs and conflicts could happen. It would be like your local 192.168.0.0 network being made public and the resulting problems would be widespread.

In 1996, when [RFC 1930](#) was written, only 5,100 ASs had been allocated and a little under 600 ASs were actively routed in the global Internet. Since that time, many more public ASNs have been assigned, leaving only a small number. For this reason 32-bit ASNs (four-octet ASNs) were defined to provide more public ASNs. [RFC 4893](#) defines 32-bit ASNs, and a FortiGate supports these larger ASNs.

Area border router

Routers within an AS advertise updates internally and only to each other. However, routers on the edge of the AS must communicate both with routers inside their AS and routers external to their AS, which are often running a different routing protocol. These routers are called Area Border Routers (ABRs) or edge routers. ABRs often run multiple routing protocols in order to redistribute traffic between different ASs that are running different protocols, such as the edge between an ISP's IS-IS routing network and a large company's OSPF network.

OSPF defines ABRs differently from other routers. In OSPF, an ABR is an OSPF router that connects another AS to the backbone AS, and is a member of all the areas it connects to. An OSPF ABR maintains an LSA database for each area that it's connected to. The concept of the edge router is present, but it's the edge of the backbone instead of the edge of the OSPF supported ASs.

Neighbor routers

Routing involves routers communicating with each other. To do this, routers need to know information about each other. These routers are called neighbor routers and are configured in each routing protocol. Each neighbor has custom settings since some routers may have functionality that other routers lack. Neighbor routers are sometimes called peers.

Generally, neighbor routers must be configured and discovered by the rest of the network before they can be integrated into the routing calculations. This is a combination of the network administrator configuring the new router with its neighbor router addresses, and the routing network discovering the new router, such as the hello packets in OSPF. That discovery initiates communication between the new router and the rest of the network.

Route maps

Route maps are a way for a FortiGate to evaluate optimum routes for forwarding packets or suppressing the routing of packets to particular destinations. Compared to access lists, route maps support enhanced packet-matching criteria. In addition, route maps can be configured to permit or deny the addition of routes to the FortiGate routing table and make changes to routing information dynamically as defined through route-map rules.

Route maps can be used for limiting both received route updates and sent route updates. This can include the redistribution of routes learned from other types of routing. For example, if you don't want to advertise local static routes to external networks, you could use a route map to accomplish this.

The FortiGate compares the rules in a route map to the attributes of a route. The rules are examined in ascending order until one or more of the rules in the route map are found to match one or more of the route attributes.

As an administrator, route maps allow you to group a set of addresses together and assign them a meaningful name. During your configuration, you can use these route-maps to speed up configuration. The meaningful names also ensure that fewer mistakes are made during configuration.

The default rule in the route map, which the FortiGate applies last, denies all routes. For a route map to take effect, it must be called by a FortiGate routing process.

The syntax for route maps are:

```
config router route-map
  edit <route-map-name>
    set comments <comment>
    config rule
      edit <route-map-rule-id>
        set action {permit | deny}
        set match-*
        set set-*
        ...
      next
    next
  end
```

The `match-*` commands allow you to match various parts of a route. The `set-*` commands allow you to set routing information once a route is matched.

For an example of how route maps can be used to create receiving or sending “groups” in routing, see ["BGP" on page 2187](#).

Access lists

Use this command to add, edit, or delete access lists. Access lists are filters used by FortiGate routing processes. For an access list to take effect, it must be called by a FortiGate routing process (for example, a process that supports RIP or OSPF). Use `access-list6` for IPv6 routing.

Access lists can be used to filter which updates are passed between routers or which routes are redistributed to different networks and routing protocols. You can create lists of rules that will match all routes for a specific router or group of routers.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or match the prefix and a more specific prefix.

If you're setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can't be exactly matched with an access-list. A prefix-list must be used for this purpose.

A FortiGate attempts to match a packet against the rules in an access list, starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found, the default action is deny.

The syntax for access lists is:

```
config router {access-list | access-list6}
  edit <access-list-name>
    set comments <comment>
    config rule
      edit <access-list-id>
        set action {permit | deny}
        set exact-match {enable | disable}
        set {prefix | prefix6} <prefix>
        set wildcard <wildcard>
      next
    next
  end
```

For an example of how access lists can be used to create receiving or sending “groups” in routing, see ["BGP" on page 2187](#).

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-protected router fail to arrive, that router is declared to be down. BFD communicates this information to the routing protocol and the routing information is updated.

BFD can run on an entire FortiGate, selected interfaces, or on a protocol, such as BGP, for all configured interfaces. The configuration hierarchy allows each lower level to override the BFD setting of the upper level. For example, if you enable BFD for an entire FortiGate, you can disable BFD for an interface or for BGP.

BFD neighbors establish if BFD is enabled in Open Shortest Path First (OSPF) or if BFD routers establish as neighbors.

The `config system` command allows you to configure whether BFD is enabled in a particular device or VDOM or individual interface, and how often the interface requires the sending and receiving of BFD information.

To configure BFD for an entire FortiGate - CLI:

```
config system settings
  set bfd {enable | disable}
  set bfd-desired-min-tx <ms>
  set bfd-required-min-rx <ms>
  set bfd-detect-mult <multiplier>
  set bfd-dont-enforce-src-port {enable | disable}
end
```

To configure BFD for an interface - CLI:

```
config system interface
  edit <interface-name>
    set bfd {global | enable | disable}
    set bfd-desired-min-tx <ms>
    set bfd-required-min-rx <ms>
    set bfd-detect-mult <multiplier>
  next
end
```

To show BFD neighbors - CLI:

```
get router {info | info6} bfd neighbor
```

To show BFD requests - CLI:

```
get router {info | info6} bfd requests
```

To configure BFD - CLI:

```
config router {bfd | bfd6}
  config neighbor
    edit <IP-address>
      set interface <interface-name>
    next
  end
```

BFD and static routes

BFD for static routes allows you to configure routing failover based on remote path failure detection. BFD removes a static route from the routing table if the FortiGate can't reach the route's destination and returns the route to the routing table if the route's destination is restored.

For example, you can add two static routes with BFD enabled. If one of the routes has a higher priority, all matching traffic uses that route. If BFD determines that the link to the gateway of the route with the higher priority is down, the higher priority route is removed from the routing table and all matching traffic uses the lower priority route. If the link to the gateway for the higher priority route comes back up, BFD adds the route back into the routing table and all matching traffic switches to use the higher priority route.

You can configure BFD for IPv4 and IPv6 static routes.

To configure BFD for static routes - CLI:

```
config router {static | static6}
  edit <sequence-number>
    set bfd {enable | disable}
  next
end
```

BFD and OSPF

You can configure BFD for Open Shortest Path First (OSPF) on a FortiGate. FortiGate supports BFD for OSPF for both IPv4 and IPv6.

To configure BFD for OSPF - CLI:

```
config router {ospf | ospf6}
  set bfd {enable | disable}
end
```

To enable BFD on a specific OSPF interface - CLI:

```
config router {ospf | ospf6}
  set bfd enable
  config {ospf-interface | ospf6-interface}
    edit <ID>
      set bfd {global | enable | disable}
    next
  end
end
```

BFD and BGP

While BGP can detect route failures, BFD can be configured to detect these failures more quickly, which allows for faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to use it.

To configure BFD for BGP - CLI:

```
config router bgp
  config neighbor
    edit <neighbor-IP-address>
      set bfd {enable | disable}
    next
  end
```

Controlling how routing changes affect active sessions

Dynamic routing changes can occur while a FortiGate is processing traffic. Routing changes that affect the routes being used for current sessions, may affect how the FortiGate continues to process the session. You can control

how active sessions are affected when dynamic routing changes occur that affects the routes the active sessions are using.

You can configure whether the FortiGate maintains the original routing for the sessions that are using the affected routes, or applies the routing table changes to the active sessions, which may cause destinations to change.

To configure how dynamic routing changes affect active sessions - CLI:

```
config system interface
  edit <interface_name>
    set preserve-session-route {enable | disable}
  next
```

where you set the following variables:

CLI option	Description
<interface_name>	The name of the interface where you want to configure how dynamic routing changes affect active sessions running through it.
enable (default)	All sessions passing through the interface when the routing changes occur, are allowed to finish and aren't affected by the routing changes.
disable	When a routing change occurs, the new routing table is applied to the active sessions passing through the interface. The routing changes may cause the destinations of the sessions to change.

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

Dynamic routing supports IPv6 on a FortiGate. The new versions of these protocols and the corresponding RFCs are:

- **RIP next generation (RIPng)** — [RFC 2080](#) - Routing Information Protocol next generation (RIPng). See RIP and IPv6.
- **BGP4+** — [RFC 2545](#), and [RFC 2858](#) Multiprotocol Extensions for IPv6 Inter-Domain Routing, and Multiprotocol Extensions for BGP-4 (MP-BGP) respectively. See BGP and IPv6.
- **OSPFv3** — [RFC 2740](#) Open Shortest Path First version 3 (OSPFv3) for IPv6 support. See OSPFv3 and IPv6.
- **Integrated IS-IS** — [RFC 5308](#) for IPv6 support. See Integrated IS-IS.

As with most advanced routing features on a FortiGate, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Admin > Settings**. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. Its widespread use started when an early version of RIP was included with BSD v4.3 Linux as the routed daemon. The Bellman–Ford algorithm, which is the routing algorithm used by RIP, first saw widespread use as the initial routing algorithm of the ARPANET.

RIP has many benefits. It is well suited to smaller networks, has near universal support on routing hardware, is quick to configure, works well if there are no redundant paths, and is in widespread use. However, because RIP updates are sent out node-by-node, it can be slow to find a path around network outages. RIP also lacks good authentication, cannot choose routes based on different quality of service methods, and can create network loops if you are not careful.

The FortiGate implementation of RIP supports RIP version 1 (see [RFC 1058](#)), RIP version 2 (see [RFC 2453](#)), and the IPv6 version RIPng (see [RFC 2080](#)).

RIPv1

In 1988, RIP version 1 (RIPv1) was released. It is defined in [RFC 1058](#). It uses classful addressing and uses broadcasting to send out updates to router neighbors. There's no subnet information included in the routing updates in classful routing. It doesn't support CIDR addressing and subnets must all be the same size. Also, route summarization isn't possible. RIPv1 has no router authentication method, so it's vulnerable to attacks through packet sniffing and spoofing.

RIPv2

In 1993, RIP version 2 (RIPv2) was developed to deal with the limitations of RIPv1. It wasn't standardized until 1998. This new version supports classless routing and subnets of various sizes. Router authentication was added, which supports MD5. MD5 hashes are an older encryption method, but this is much improved over no security at all. In RIPv2, the hop count limit remained at 15, in order to be backwards compatible with RIPv1. It also uses multicasting to send the entire routing table to router neighbors, which reduces the traffic for devices that aren't participating in RIP routing. Routing tags were also added, which allow internal routes or redistributed routes to be identified as such.

RIPng

RIPng, defined in [RFC 2080](#), is an extension of RIPv2 and is designed to support IPv6. However, RIPng varies from RIPv2 in that it's not fully backwards compatible with RIPv1. RIPng doesn't support RIPv1 update authentication and relies on IPsec instead. It doesn't allow the attaching of tags to routes, as in RIPv2. RIPng requires specific encoding of the next hop for a set of route entries, unlike RIPv2 that encodes the next-hop into each route entry.

RIP terminology and parts

Before you can understand how RIP functions, you need to understand some of the main concepts and parts of RIP.

RIP and IPv6

RIP Next Generation (RIPng) is a new version of RIP and includes support for IPv6.

The FortiGate `config router ripng` command is almost the same as the `config router rip` command, except that IPv6 addresses are used. Also, if you're going to use prefix or access lists with RIPng, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to troubleshoot RIPng, it's the same as with RIP but specify the different protocol and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table or other related information.

If you want to route IPv4 traffic over an IPv6 network, you can use the command `config system ipv6-tunnel` to configure the FortiGate to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command isn't supported in transparent mode.

For example, if you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01::, where it will need access to an IPv4 network again, use the following CLI commands:

```
config system ipv6-tunnel
  edit test_tunnel
    set destination 2002:A0A:A01::
    set interface port1
    set source 2002:C0A8:3201::
  next
```

The CLI commands associated with RIPng include:

```
config router ripng
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

Default information originate option

The default information originate option is the second advanced option for RIP in the FortiGate GUI, right after metric. Enabling default-information-originate will generate and advertise a default route into the FortiGate device's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. RIP does not create the default route unless you use the always option.

Select **Disable** if you experience any issues or if you wish to advertise your own static routes into RIP updates.

You can enable or disable default-information-originate in **Router > Dynamic > RIP**, under **Advanced Options**, or use the CLI.

The CLI commands associated with default information originate include:

```
config router rip
  set default-information-originate {enable | disable}
end
```

Update, timeout, and garbage timers

RIP uses various timers to regulate its performance including an update timer, a timeout timer, and a garbage timer. The FortiGate default timer settings (30, 180, and 120 seconds) are effective in most configurations. If you change these settings, ensure that the new settings are compatible with local routers and access servers.

The timeout period should be at least three times longer than the update period. If the update timer is smaller than the timeout or garbage timers, you'll experience an error.

You can set the three RIP timers in **Router > Dynamic > RIP**, under **Advanced Options**, or use the CLI.

To configure garbage, timeout, and update timers - CLI:

```
config router rip
  set timeout-timer <seconds>
  set update-timer <seconds>
  set garbage-timer <seconds>
end
```

Update timer

The update timer determines the interval between routing updates. This value is usually set to 30 seconds. There's some randomness added to help prevent network traffic congestion, which could result from all routers attempting to update their neighbors simultaneously. The update timer should be at least three times smaller than the timeout timer or you'll experience an error.

If you're experiencing significant RIP traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you'll experience timeouts that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time a FortiGate will keep a reachable route in the routing table while no updates for that route are received. If the FortiGate receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period or you'll experience an error.

If you're experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods. It may be a considerable amount of time before the FortiGate is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that a FortiGate advertises a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove older ones faster. This will result in a smaller routing table, which is useful if you have a very large network, or if your network changes frequently.

Authentication and key chain

RIP version 2 (RIPv2) uses authentication keys to ensure that the routing information exchanged between routers is reliable. RIP version 1 (RIPv1) has no authentication. For authentication to work, both the sending and receiving routers must be set to use authentication and must be configured with the same keys.

The sending and receiving routers need to have their system dates and times synchronized to ensure both ends are using the same keys at the proper times. However, you can overlap the key lifetimes to ensure that a key is always available even if there's some difference in the system times.

A key chain is a list of one or more authentication keys, including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. A FortiGate migrates from one key to the next according to the scheduled send and receive lifetimes.

The key-chain command is a CLI router command. You use this command to manage RIPv2 authentication keys. You can add, edit, or delete keys identified by the specified key number.

This example shows how to configure a key chain with two keys that are valid sequentially in time. This example creates a key chain called `rip_key` that has a password of "fortinet". The accepted and send lifetimes are both set to the same values: a start time of 9:00 am on February 23, 2010 and an end time of 9:00 am on March 17, 2010. A second key is configured with a password of "my_fortigate" that is valid from March 17, 2010 9:01am to April 1 2010 9:00am. This "rip_key" key chain is then used on the port1 interface in RIP.

```
config router key-chain
  edit rip_key
    config key
      edit 1
        set accept-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
        set key-string "fortinet"
        set send-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
      next
      edit 2
        set accept-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
        set key-string "my_fortigate"
        set send-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
      next
    next
  end
config router rip
  config interface
    edit port1
      set auth-keychain "rip_key"
    next
  end
```

The CLI commands associated with authentication keys include:

```
config router key-chain

config router rip
  config interface
    edit <interface>
      set auth-keychain <key_chain_name>
      set auth-mode {none | text | md5}
      set auth-string <password_string>
    next
  end
```

Access lists

Access lists are filters used by the FortiGate device's RIP and OSPF routing. An access list provides a list of IP addresses and the action to take for them. Essentially, an access list makes it easy to group addresses that will

be treated the same way into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include and specify the action to take for it. For example, if you want all traffic from one department to be routed a particular way, even in different buildings, you can add all of the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

A FortiGate attempts to match a packet against the rules in an access list, starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If a match isn't found, the default action is deny.

Access lists greatly speed up configuration and network management. When there's a problem, you can check each list instead of individual addresses. Also, it's easier to troubleshoot because if all addresses on one list have problems, many possible causes can be eliminated right away.

If you're using the RIPng or OSPF+ IPv6 protocols, you'll need to use access-list6, which is the IPv6 version of the access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of 10.10.10.10 and 11.11.11.11, enter the command:

```
config router access-list
  edit test_list
    config rule
      edit 1
        set prefix 10.10.10.10 255.255.255.255
        set action permit
        set exact-match enable
      next
      edit 2
        set prefix 11.11.11.11 255.255.255.255
        set action permit
        set exact-match enable
      next
    next
  end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the access-list6 command, as follows:

```
config router access-list6
  edit test_list_ip6
    config rule
      edit 1
        set prefix6 2002:A0A:A0A:0:0:0:0:0/48
        set action deny
      next
      edit 2
        set prefix6 2002:B0B:B0B:0:0:0:0:0/48
        set action deny
      next
    next
  end
```

To use an access list, you must call it from a routing protocol, such as RIP. The following example uses the access list from the previous example, called `test_list`, to match routes coming in on the port1 interface. When

there's a match, it will add 3 to the hop count metric for those routes to artificially increase. Enter the following command:

```
config router rip
  config offset-list
    edit 5
      set access-list test_list
      set direction in
      set interface port1
      set offset 3
      set status enable
    next
  end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can't be exactly matched with an access list. A prefix list must be used for this purpose

How RIP works

As one of the original modern dynamic routing protocols, RIP is straightforward. Its routing algorithm isn't complex and there are some options that allow fine tuning. It is relatively simple to configure RIP on a FortiGate.

From [RFC 1058](#):

Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.

RIP versus static routing

RIP was one of the earliest dynamic routing protocols to work with IP addresses. As such, it's not as complex as more recent protocols. However, RIP is a big step forward from simple static routing.

While RIP may be slow in response to network outages, static routing has zero response. The same is true for convergence; static routing has zero convergence. Both RIP and static routing have a limited hop count, so it's not a strength or a weakness. Count to infinity can be a problem, but can typically be fixed as it happens, or is the result of a network outage that would cause even worse problems on a static routing network.

This compares to static routing where each time a packet needs to be routed, the FortiGate can send it only to the next hop towards the destination. That next hop then forwards it, and so on until it arrives at its destination. RIP keeps more routing information on each router so the FortiGate can send the packet further towards its destination before it has to be routed again toward its destination. RIP uses a smaller amount of table lookups, and therefore fewer network resources, than static routing. Also, since RIP is updated on neighboring routes, it's aware of new routes or dead routes that static routing would not be aware of.

Overall, RIP is a large step forward when compared to static routing.

RIP hop count

RIP uses hop count as the metric for choosing the best route. A hop count of 1 represents a network that is connected directly to a FortiGate, while a hop count of 16 represents a network that can't be reached. Each network that a packet travels through to reach its destination usually counts as one hop. When the FortiGate

compares two routes to the same destination, it adds the route having the lowest hop count to the routing table. As you can see in ["RIP packet structure" on page 2120](#), the hop count is part of a RIP v2 packet.

Similarly, when RIP is enabled on an interface, the FortiGate sends RIP responses to neighboring routers on a regular basis. The updates provide information about the routes in the FortiGate device's routing table, subject to the rules that you specify for advertising those routes. You can specify how often the FortiGate sends updates, the period of time a route can be kept in the routing table without being updated, and for routes that aren't updated regularly, you can specify the period of time that the unit advertises a route as unreachable before it's removed from the routing table.

If hops are weighted higher than one, it's very easy to reach the upper limit. This higher weighting effectively limits the size of your network, depending on the numbers used. Merely changing from the default of 1.0 to 1.5 will lower the effective hop count from 15 to 10. This is acceptable for smaller networks, but can be a problem as your network expands over time.

In RIP, you can use the `offset` command to artificially increase the hop count of a route. Doing this will make this route less preferred and, in turn, it will get less traffic. Offsetting routes is useful when you have network connections that have different bandwidths, levels of reliability, or costs. In each of these situations you still want the redundancy of multiple route access, but you don't want the bulk of your traffic using these less preferred routes. For an example of RIP offset, see ["Access lists" on page 2113](#).

The Bellman–Ford routing algorithm

The routing algorithm used by RIP was first used in 1967 as the initial routing algorithm of the ARPANET. The Bellman–Ford algorithm is distributed because it involves a number of nodes (routers) within an Autonomous system, and consists of the following steps:

1. Each node calculates the distances between itself and all other nodes within the AS and stores this information as a table.
2. Each node sends its table to all neighboring nodes.
3. When a node receives distance tables from its neighbors, it calculates the shortest routes to all other nodes and updates its own table to reflect any changes.

To examine how this algorithm functions let us look at a network with four routers: routers 1 through 4. The distance from Router1 to Router2 is 2 hops, Router1 to Router3 is 3 hops, and Router2 to Router3 is 4 hops. Router4 is only connected to Router2 and Router3, each distance being 2 hops.

1. Router1 finds all of the distances to the other three routers: Router 2 is 2, Router 3 is 3. Router1 doesn't have a route to Router4.
2. Router2, Router3, and Router4 perform the same calculations from their point of views.
3. Once Router1 gets an update from Router 2 or Router3, it will get their route to Router4. At that point, it now has a route to Router4 and installs that in its local table.
4. If Router1 gets an update from Router3 first, it has a hop count of 5 to reach Router4, but when Router2 sends its update, Router1 will go with Router2's shorter 4 hops to reach Router4. Future updates don't change this unless they are shorter than 4 hops or the routing table route goes down.

Example of a RIP algorithm

Step 1

Router1 finds the distance to other routers in the network.

It currently has no route to Router4.

Router1 routing table:

- Distance to Router2 = 2 hops
- Distance to Router3 = 3 hops

Step 2

All routers do the same as Router1 and send out updates containing their routing table.

Note that Router1 and Router4 don't update each other, but rely on Router2 and Router3 to pass along accurate updates.

Step 3

Each router looks at the updates it has received and adds any new or shorter routes to its table.

Router1's updated table:

- Distance to Router2 = 2 hops
- Distance to Router3 = 3 hops

- Distance to Router4 = 4 or 5 hops

Step 4

Router1 installs the shortest route to Router4 and the other routes to it are removed from the routing table.

Router1's complete table:

- Distance to Router2 = 2 hops
- Distance to Router3 = 3 hops
- Distance to Router4 = 4 hops

The good part about the Bellman-Ford algorithm in RIP is that the router only uses the information it needs from the update. If there are no newer, better routes than the ones the router already has in its routing table, there's no need to change its routing table. And no change means no additional update, and therefore less traffic. But even when there's update traffic, the RIP packets are very small so it takes many updates to affect overall network bandwidth. For more information about RIP packets, see ["RIP packet structure" on page 2120](#).

The main disadvantage of the Bellman–Ford algorithm in RIP is that it doesn't take weightings into consideration. While it's possible to assign different weights to routes in RIP, doing so severely limits the effective network size by reducing the hop count limit. Also, other dynamic routing protocols can take route qualities, such as reliability or delay, into consideration to provide not only the physically shortest routes but also the fastest or more reliable routes.

Another disadvantage of the Bellman-Ford algorithm is due to the slow updates passed from one RIP router to the next. This results in a slow response to changes in the network topology, which in turn results in more attempts to use routes that are down and that wastes time and network resources.

Passive versus active RIP interfaces

Normally, the FortiGate routing table is kept up to date by periodically asking the neighbors for routes, and sending your routing updates out. This has the downside of generating a lot of extra traffic for large networks. The solution to this problem is passive interfaces.

A standard interface that supports RIP is active, by default. It sends and receives updates by actively communicating with its neighbors. A passive RIP interface doesn't send out updates. It only listens to the updates of other routers. This is useful in reducing network traffic, and if there are redundant routers in the network that will send out essentially the same updates all the time.

The following example shows how to create a passive RIPv2 interface on port1 using MD5 authentication and a key chain called `passiveRIPv2`, which has already been configured. Note that in the CLI, you enable passive by disabling `send-version2-broadcast`.

To create a passive RIP interface - GUI:

1. Go to **Router > Dynamic > RIP**.
2. Next to **Interfaces**, select **Create**.
3. Select port1 as the **Interface**.
4. Select 2 as both the **Send Version** and **Receive Version**.
5. Select MD5 for **Authentication**.
6. Select the `passiveRIPv2` **Key-chain**.
7. Select **Passive Interface**.
8. Select **OK** to accept this configuration and return to the main RIP display page.

To create a passive RIP v2 interface on port1 using MD5 authentication - CLI:

```
config router rip
  config interface
    edit port1
      set send-version2-broadcast disable
      set auth-keychain "passiveRIPv2"
      set auth-mode md5
      set receive-version 2
      set send-version 2
    next
  end
```

RIP packet structure

It's hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how it's exchanged will help you to better understand the RIP protocol and better configure your network for it.

This section provides information about the contents of RIPv1 and RIPv2 packets.

RIP version 1

RIP version 1 (RIPv1), or RIP IP, packets are 24 bytes in length with some empty areas left for future expansion.

RIP IP packets

1-byte command	1-byte version	2-byte zero field	2-byte AFI	2-byte zero field
4-byte IP address	4-byte zero field	4-byte zero field	4-byte metric	

A RIPv1 packet contains the following fields:

- **Command:** Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple RIP packets are used to convey information from large routing tables.
- **Version:** Specifies the RIP version used. This field can signal different, potentially incompatible versions.
- **Zero field:** This field defaults to zero and is not used by [RFC 1058](#) RIP.
- **Address-family identifier (AFI):** Specifies the address family used. RIP is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.
- **IP Address:** Specifies the IP address for the entry.
- **Metric:** This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable, the metric is 16.

RIP version 2

RIP version 2 (RIPv2) has more features than RIPv1, which is reflected in its packets that carry more information. All but one of the empty zero fields in RIPv1 packets are used in RIPv2.

RIPv2 packets

1-byte command	1-byte version	2-byte unused	2-byte AFI	2-byte route tag
4-byte IP address	4-byte subnet	4-byte next hop	4-byte metric	

A RIPv2 packet contains the fields described above for RIPv1, as well as the following:

- **Unused:** Has a value set to zero and is intended for future use
- **Route tag:** Provides a method for distinguishing between internal routes learned by RIP and external routes learned from other protocols.

- **Subnet mask:** Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.
- **Next hop:** Indicates the IP address of the next hop to which packets for the entry should be forwarded.

Troubleshooting RIP

This section is about troubleshooting RIP. For general troubleshooting information, see the *Troubleshooting Handbook*.

Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there's a routing loop, that normal path doubles back on itself, creating a loop. When there are loops, the network has problems getting information to its destination. Loops also prevent the network from returning to the source to report the inaccessible destination.

A routing loop occurs when a normally functioning network has an outage and one or more routers are offline. When packets encounter this, they attempt an alternate route maneuver around the outage. During this phase, it's possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is also blocked by the outage, a hop back, and possibly the original hop forward, may be selected. If this continues, it can consume not only network bandwidth but also many resources on the affected routers. The worst part is this situation will continue until the network administrator changes the router settings or the downed routers come back online.

Effect of routing loops on the network

In addition to this "traffic jam" of routed packets, every time the routing table for a router changes, that router sends an update out to all of the RIP routers connected to it. In a network loop, it's possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How to spot a routing loop

Anytime network traffic slows down, you'll ask yourself if it's a network loop. Slowdowns are often normal, aren't a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown that doesn't return to normal quickly, you need to do serious troubleshooting quickly.

If you're not running SNMP, link health monitoring, or you have non-Fortinet routers in your network, you can use networking tools, such as ping and traceroute, to define the outage on your network and begin to fix it. Ping, traceroute, and other basic troubleshooting tools are largely the same between static and dynamic and are covered in ["Advanced static routing" on page 2062](#).

Check your logs

If your routers log events to a central location, it can be easy to check your network logs for any outages.

In the FortiGate GUI, go to **Log & Report**. You should look at both event logs and traffic logs. Events to look for generally fall under CPU and memory usage, interfaces going offline (due to link health monitoring), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and its location as soon as it happens.

Ideally, you can configure SNMP on all FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops - GUI:

1. Go to **System > Config > SNMP**.
2. Enable **SMTP Agent** and select **Apply**.
Optionally, enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
3. Under **SNMP v1/v2** or **SNMP v3** as appropriate, select **Create New**.

SNMP v3

User Name	Enter the SNMP user ID.
Security Level	Select authentication or privacy as desired. Select the authentication or privacy algorithms to use and enter the required passwords.
Notification Host	Enter the IP addresses of up to 16 hosts to notify.
Enable Query	Select. The Port should be 161. Ensure that your security policies allow ports 161 and 162 (SNMP queries and traps) to pass.

SNMP v1/v2

Hosts	Enter the IP addresses of up to 8 hosts to notify.
Queries	Enable v1 and/or v2 as needed. The Port should be 161. Ensure that your security policies allow port 161 to pass.
Traps	Enable v1 and/or v2 as needed. The Port should be 162. Ensure that your security policies allow port 162 to pass.

4. Select the events for which you want notification. For routing loops this should include **CPU usage is high**, **Memory is low**, and possibly **Log disk space is low**. If there are problems the log will fill up quickly and the FortiGate device's resources will be overused.
5. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Use link health monitoring

Another tool available to you on a FortiGate is the link health monitor. You can detect possible routing loops with link health monitors. You can configure the FortiGate to ping a gateway at regular intervals to ensure it's online and working. When the gateway isn't accessible, that interface is marked as down.

For more information about link health monitoring, see ["Link health monitor" on page 2025](#).

Use email alerts for failed gateways

You can detect possible routing loops with email alerts.

To configure notification of failed gateways - GUI:

1. Go to **Log & Report > Report > Local** and enable **Email Generated Reports**.
2. Enter your email details.
3. Select **Apply**.

You might also want to log CPU and Memory usage because a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate can't connect to the next router, the FortiGate brings down the interface and alert you with an email about the outage.

Look at the packet flow

If you want to see what is happening on your network, look at the packets traveling on the network. This is the same idea as police pulling over a car and asking the driver where they have been and what the conditions were like.

The method used in the troubleshooting sections ["Debugging IPv6 on RIPng" on page 2124](#) and on debugging the packet flow also apply here. In this situation, you're looking for routes that have metrics higher than 15, as this indicates they are unreachable.

Ideally, if you debug the flow of the packets and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you've mapped the problem on your network and determined that it's a routing loop, there are a number of steps you can take to correct it:

1. Get any offline routers back online. This may be a simple reboot or you may have to replace hardware. Often, this first step will restore your network to its normal operation once the routing tables are updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Holddowns and triggers for updates

One of the potential problems with RIP is the frequent routing table updates that are sent every time there's a change to the routing table. If your network has many RIP routers, these updates can start to slow your network down. Also, if you have a particular route that has bad hardware, it might be going up and down frequently, which will generate an overload of routing table updates.

One of the most common solutions to this problem is to use holddown timers and triggers for updates. These slow down the updates that are sent out and help prevent a potential flood.

Holddown timers

The holddown timer activates when a route is marked down. Until the timer expires, the router doesn't accept any new information about that route. This is very useful if you have a flapping route because it'll prevent your router from sending out updates and being part of the problem in flooding the network. The potential downside is if the route comes back up before the timer expires, that route will be unavailable for that period of time. This is only a problem if this is a major route used by the majority of your traffic. Otherwise, this is a minor problem as traffic can be re-routed around the outage.

Triggers

Triggered RIP is an alternate update structure that is based around limiting updates to only specific circumstances. The most basic difference is that the routing table is only updated when a specific request is sent to update, instead of every time the routing table changes. Updates are also triggered when a unit is powered on, which can include the addition of new interfaces or devices to the routing structure, or devices returning to being available after being unreachable.

Split horizon and poison reverse updates

Split horizon is best explained with an example. If there are three routers linked serially, called routerA, routerB, and routerC. RouterA is only linked to routerB, RouterC is only linked to routerB, and routerB is linked to both routerA and routerC. To get to routerC, routerA must go through routerB. If the link to routerC goes down, it's possible that routerB will try to use routerA's route to get to routerC. This route is A-B-C, so it'll loop endlessly between routerA and routerB.

This situation is called a split horizon because from routerB's point of view the horizon stretches out in each direction but in reality it's only on one side. Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This poisoned route is marked as unreachable for routers that can't use it. In RIP, this means that the route is marked with a distance of 16.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit, including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
```

```
diagnose ipv6 router rip all enable
```

These three commands:

- Turn on debugging, in general
- Set the debug level to information, which is a verbose reporting level
- Turn on all RIP router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a reply received in response.

For more information, see ["Testing the IPv6 RIPng information" on page 2146](#).

Simple RIP example

This is an example of a typical medium-sized network configuration using RIP routing.

Your company has 3 small local networks, one for each department. These networks are connected by RIP, and then connected to the Internet. Each subnet has more than one route for redundancy. There are two central routers that are both connected to the Internet and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running RIP, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running, those will need to be redistributed through the RIP network.

To keep the example simple, there will be no authentication of router traffic.

With RIP properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. RIP is good for a smaller network due to its lack of complex configurations.

Network layout and assumptions

Basic network layout

Your company has 3 departments each with their own network: Sales, R&D, and Accounting. Each network has routers that are not running RIP and FortiGate devices running RIP.

The R&D network has two RIP routers, and each is connected to both other departments as well as being connected to the Internet through the ISP router. The links to the Internet are indicated in black.

The three internal networks do not run RIP. They use static routing because they are small networks. This means the FortiGate devices have to redistribute any static routes they learn so that the internal networks can communicate with each other.

Where possible in this example, the default values will be used (or the most general settings). This is intended to provide an easier configuration that will require less troubleshooting.

In this example, the routers, networks, interfaces used, and IP addresses are as follows. Note that the interfaces that connect Router2 and Router3 also connect to the R&D network.

RIP example network topology

Network	Router	Interface & alias	IP address		
Sales	Router1	port1 (internal)	10.11.101.101		
		port2 (router2)	10.11.201.101		
		port3 (router3)	10.11.202.101		
		port1 (internal)	10.12.101.102		
	Router2	port2 (router1)	10.11.201.102		
		port3 (router4)	10.14.201.102		
		port4 (ISP)	172.20.120.102		
		R&D	Router3	port1 (internal)	10.12.101.103
port2 (router1)	10.11.201.103				
port3 (router4)	10.14.202.103				
port4 (ISP)	172.20.120.103				
Router4	port1 (internal)		10.14.101.104		
	Accounting		Router4	port2 (router2)	10.14.201.104
	port3 (router3)		10.14.202.104		

Network topology for the simple RIP example

Assumptions

This example makes the following assumptions:

- All FortiGate devices have 5.0 firmware and are running factory default settings.
- All CLI and GUI navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate devices have interfaces labeled port1 through port4, as required.
- All firewalls have been configured for each FortiGate to allow the required traffic to flow across interfaces.
- Only FortiGate devices are running RIP on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.
- Router2 and Router3 each have their own connection to the Internet, indicated in black in the diagram above.

General configuration steps

This example is very straightforward. The steps involved are:

- [Configuring FortiGate system information](#)
- [Configuring FortiGate RIP router information](#)
- [Configuring other networking devices](#)
- [Testing network configuration](#)

Configuring FortiGate system information

You must configure the hostname and interfaces for each FortiGate.

For IP numbering, Router2 and Router3 use the numbering for the other routers, where needed.

Router2 and Router3 have link health monitoring enabled on the ISP interfaces using Ping. Remember to contact the ISP and confirm their server has ping enabled.

Configure the hostname, interfaces, and default route

To configure Router1 system information - GUI:

1. Go to **System > Settings**.
2. In the **Host name** field, enter `Router1`.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.5/255.255.255.0
Interface	port2 (router2)
Administrative Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.5/255.255.255.0
Interface	port3 (router3)
Administrative Distance	40

6. Go to **Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Internal sales network
Interface State	Enabled

9. Edit port2 (router2) interface.
10. Set the following information, and select **OK**.

Alias	router2
IP/Network Mask	10.11.201.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Link to R&D network & Internet through Router2
Interface State	Enabled

11. Edit port3 (router3) interface.

12. Set the following information, and select **OK**.

Alias	router3
IP/Network Mask	10.11.202.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Link to R&D network and Internet through Router3
Interface State	Enabled

To configure Router1 system information - CLI:

```

config system global
    set hostname Router1
end

config router static
    edit 1
        set device "port2"
        set distance 45
        set gateway 10.11.201.102
    next
    edit 2
        set device "port3"
        set distance 45
        set gateway 10.11.202.103
    end
end

config system interface
    edit port1
        set alias internal
        set ip 10.11.101.101/255.255.255.0
        set allowaccess https ssh ping
        set description "Internal sales network"
    next
    edit port2
        set alias ISP
        set allowaccess https ssh ping
        set ip 10.11.201.101/255.255.255.0

```

```

        set description "Link to R&D network & Internet through Router2"
    next
    edit port3
        set alias router3
        set ip 10.11.202.101/255.255.255.0
        set allowaccess https ssh ping
        set description "Link to R&D network & Internet through Router2"
    end
end
end

```

To configure Router2 system information - GUI:

1. Go to **System > Settings**.
2. In the **Host name** field, enter `Router2`.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.5/255.255.255.0
Interface	port4 (ISP)
Administrative Distance	5

5. Go to **Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	R&D internal network and Router3
Interface State	Enabled

8. Edit port2 (router1) interface.
9. Set the following information and select **OK**.

Alias	router1
IP/Network Mask	10.12.201.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Link to Router1 and the Sales network
Interface State	Enabled

10. Edit port3 (router4) interface.
11. Set the following information and select **OK**.

Alias	router4
IP/Network Mask	10.12.301.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Link to Router4 and the accounting network
Interface State	Enabled

12. Edit port4 (ISP) interface.
13. Set the following information and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Comments	Internet through ISP
Interface State	Enabled

To configure Router2 system information - CLI:

```

config system global
    set hostname Router2
end
config router static
    edit 1
        set device "port4"
        set distance 5
        set gateway 172.20.130.5
    end
end
config system interface
    edit port1
        set alias internal
        set ip 10.11.101.102/255.255.255.0
        set allowaccess https ssh ping
        set description "Internal RnD network and Router3"
    next
    edit port2
        set alias router1
        set allowaccess https ssh ping
        set ip 10.11.201.102/255.255.255.0
        set description "Link to Router1"
    next

```

```

edit port3
    set alias router3
    set ip 10.14.202.102/255.255.255.0
    set allowaccess https ssh ping
    set description "Link to Router4"
next
edit port4
    set alias ISP
    set ip 172.20.120.102/255.255.255.0
    set allowaccess https ssh ping
    set description "ISP and Internet"
end
end

```

To configure Router3 system information - GUI:

1. Go to **System > Settings**.
2. In the **Host name** field, enter Router3.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.5/255.255.255.0
Interface	port4 (ISP)
Administrative Distance	5

5. Go to **Network > Interfaces**.
6. Edit port1 (internal) interface.
7. Set the following information and select **OK**.

Alias	internal
IP/Network Mask	10.12.101.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	R&D internal network and Router2
Interface State	Enabled

8. Edit port2 (router1) interface.
9. Set the following information and select **OK**.

Alias	router1
IP/Network Mask	10.13.201.103/255.255.255.0

Administrative Access	HTTPS SSH PING
Comments	Link to Router1 and Sales network
Interface State	Enabled

10. Edit port3 (router4) interface.

11. Set the following information and select **OK**.

Alias	router4
IP/Network Mask	10.13.301.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Link to Router4 and accounting network
Interface State	Enabled

12. Edit port4 (ISP) interface.

13. Set the following information and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect and Identify Devices	enable
Comments	Internet and ISP
Interface State	Enabled

To configure Router3 system information - CLI:

```

config system global
    set hostname Router3
end
config router static
    edit 1
        set device "port4"
        set distance 5
        set gateway 172.20.130.5
    end
end
config system interface
    edit port1
        set alias internal
        set ip 10.12.101.103/255.255.255.0
        set allowaccess https ssh ping
        set description "Internal RnD network and Router2"
    end
end

```

```

next
edit port2
    set alias ISP
    set allowaccess https ssh ping
    set ip 10.11.201.103/255.255.255.0
    set description "Link to Router1"
next
edit port3
    set alias router3
    set ip 10.14.202.103/255.255.255.0
    set allowaccess https ssh ping
    set description "Link to Router4"
next
edit port4
    set alias ISP
    set ip 172.20.120.103/255.255.255.0
    set allowaccess https ssh ping
    set description "ISP and Internet"
end
end

```

To configure Router4 system information - GUI:

1. Go to **System > Settings**.
2. In the **Host name** field, enter Router4.
3. Go to **Network > Static Routes**.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.5/255.255.255.0
Interface	port2 (router2)
Administrative Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.5/255.255.255.0
Interface	port3 (router3)
Administrative Distance	40

6. Go to **Network > Interfaces**.
7. Edit port 1 (internal) interface.
8. Set the following information and select **OK**.

Alias	internal
--------------	----------

IP/Network Mask	10.14.101.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Internal accounting network
Interface State	Enabled

9. Edit port 2 (router2) interface.
10. Set the following information and select **OK**.

Alias	router2
IP/Network Mask	10.14.201.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Link to R&D network & Internet through Router2
Interface State	Enabled

11. Edit port 3 (router3) interface.
12. Set the following information and select **OK**.

Alias	router3
IP/Network Mask	10.14.301.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Link to R&D network and Internet through Router3
Interface State	Enabled

To configure Router4 system information - CLI:

```

config system global
    set hostname Router4
end
config router static
    edit 1
        set device "port2"
        set distance 45
        set gateway 10.14.201.102
    next
    edit 2
        set device "port3"
        set distance 45
        set gateway 10.14.202.103
    end
end
config system interface

```

```
edit port1
    set alias internal
    set ip 10.14.101.104/255.255.255.0
    set allowaccess https ssh ping
    set description "Internal sales network"
next
edit port2
    set alias router2
    set allowaccess https ssh ping
    set ip 10.14.201.104/255.255.255.0
    set description "Link to R&D network & Internet through Router2"
next
edit port3
    set alias router3
    set ip 10.14.202.104/255.255.255.0
    set allowaccess https ssh ping
    set description "Link to R&D network & Internet through Router2"
end
end
```

Configuring FortiGate RIP router information

With the interfaces configured, RIP can now be configured on the FortiGate.

For each FortiGate, the following steps will be taken:

- Configure RIP version used
- Redistribute static networks
- Add networks serviced by RIP
- Add interfaces that support RIP on the FortiGate

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures. Repeat the procedures once for each FortiGate.

Configure RIP settings on Router1 and Router4 - GUI:

1. Go to **Network > RIP**.
2. Select **2** for **Version**.
3. In **Advanced Options**, under **Redistribute** enable **Static**. Leave the other advanced options at their default values.
4. Under **Networks**, add the following networks:
 - 10.11.0.0/255.255.0.0
 - 10.12.0.0/255.255.0.0
 - 10.14.0.0/255.255.0.0
 - 172.20.120.0/255.255.255.0
6. Under **Interfaces**, select **Create New** and set the following information:

Interface	port1 (internal)
Passive	disabled

Authentication	None
Send Version	Both
Receive Version	Both

7. Under **Interfaces** select **Create New** and set the following information:

Interface	port2 (router2)
Passive	disabled
Authentication	None
Send Version	Both
Receive Version	Both

8. Under **Interfaces**, select **Create New** and set the following information:

Interface	port3 (router3)
Passive	disabled
Authentication	None
Send Version	Both
Receive Version	Both

Configure RIP settings on Router1 and Router4 - CLI:

```

config router rip
  set version 2
  config interface
    edit "port1"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port2"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port3"
      set receive-version 1 2
      set send-version 1 2
    end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
      set prefix 10.12.0.0 255.255.0.0

```

```

    next
    edit 3
        set prefix 10.14.0.0 255.255.0.0
    next
    edit 4
        set prefix 172.20.120.0 255.255.255.0
    end
    config redistribute "static"
        set status enable
    end
end
end

```

Configure RIP settings on Router2 and Router3 - GUI:

1. Go to **Network > RIP**.
2. Select **2** for **RIP**.
3. In **Advanced Options**, under **Redistribute** enable **Static**. Leave the other advanced options at their default values.
4. Under **Networks**, add the following networks:
 - 10.11.0.0/255.255.0.0
 - 10.12.0.0/255.255.0.0
 - 10.14.0.0/255.255.0.0
 - 172.20.120.0/255.255.255.0
6. Under **Interfaces**, select **Create New** and set the following information:

Interface	port1 (internal)
Passive	disabled
Authentication	None
Send Version	Both
Receive Version	Both

7. Under **Interfaces**, select **Create New** and set the following information:

Interface	port2 (router1)
Passive	disabled
Authentication	None
Send Version	Both
Receive Version	Both

8. Under **Interfaces**, select **Create New** and set the following information:

Interface	port3 (router4)
Passive	disabled
Authentication	None
Send Version	Both
Receive Version	Both

9. Under **Interfaces**, select **Create New** and set the following information:

Interface	port4 (ISP)
Passive	disabled
Authentication	None
Send Version	Both
Receive Version	Both

Configure RIP settings on Router2 and Router3 - GUI:

```

config router rip
  set version 2
  config interface
    edit "port1"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port2"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port3"
      set receive-version 1 2
      set send-version 1 2
    end
    edit "port4"
      set receive-version 1 2
      set send-version 1 2
    end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
      set prefix 10.12.0.0 255.255.0.0
    next
    edit 3
      set prefix 10.14.0.0 255.255.0.0
    next
    edit 4

```

```
        set prefix 172.20.120.0 255.255.255.0
    end
    config redistribute "static"
        set status enable
    end
end
```

Configuring other networking devices

In this example, there are two groups of other devices on the the network: internal devices and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers, and other network devices. Once the FortiGate devices are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise, there should be no configuration required.

The second group of devices is the ISP. This consists of the RIP router the FortiGate Router2 and Router3 connect to. You need to contact your ISP and ensure they have your information for your network, such as the IP addresses of the connecting RIP routers, what version of RIP your network supports, and what authentication (if any) is used.

Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the Internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult ["Troubleshooting RIP" on page 2121](#).

IPsec auto discovery support

The following routing settings are available in the CLI to support IPsec auto discovery. They are designed for:

- Supporting the RIPvng (RIP next generation) network command
- Limiting the maximum metric allowed to output for RIPvng
- Fix NSM missing kernel address update information

The actual new settings are:

```
config router rip
    set max-out-metric <integer value 1 - 15>
end

config router ripng
    set max-out-metric <integer value 1 - 15>
end

config router ripng
    config network
        edit <network-ID>
            set prefix <IPv6-prefix>
        end
    end
```

RIPng: RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate devices running the RIPng dynamic routing protocol. Both FortiGate devices are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network, allowing it to reach the Internet at all times.

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate devices running the RIPng dynamic routing protocol. Both FortiGate devices are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network, allowing it to reach the Internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

Where possible in this example, the default values will be used (or the most general settings). This is intended to provide an easier configuration that will require less troubleshooting.

In this example, the routers, networks, interfaces used, and IP addresses are as follows.

Example RIP network topology

Network	Router	Interface & alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Example network topology for IPV6 RIPng

Assumptions

The following assumptions have been made concerning this example.

- All FortiGate devices have 5.0 firmware and are running factory default settings.
- All CLI and GUI navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate devices have interfaces labeled port1 and port2, as required.
- All firewalls have been configured for each FortiGate to allow the required traffic to flow across interfaces.
- All network devices support IPv6 and are running RIPng.

Configuring the FortiGate system information

Each FortiGate needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - GUI:

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter "Router1".
4. Go to **System > Config > Features**.

5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router1 - CLI:

```

config system global
    set hostname Router1
    set gui-ipv6 enable
end
config system interface
    edit port1
        set alias internal
        set allowaccess https ping ssh
        set description "Internal RnD network"
        config ipv6
            set ip6-address 2002:a0b:6565::/0
        end
    next
    edit port2
        set alias ISP
        set allowaccess https ping ssh
        set description "ISP and Internet"
        config ipv6
            set ip6-address 2002:AC14:7865::
        end
    end
end

```

To configure system information on Router2 - GUI:

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter "Router2".
4. Go to **System > Config > Features**.
5. In **Basic Features**, enable **IPv6**, and select **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information and select **OK**.

Alias	internal
IP/Network Mask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information and select **OK**.

Alias	ISP
IP/Network Mask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet
Administrative Status	Up

To configure system information on Router2 - CLI:

```

config system global
    set hostname Router2
    set gui-ipv6 enable
end
config system interface
    edit port1
        set alias internal
        set allowaccess https ping ssh
        set description "Internal RnD network"
        config ipv6
            set ip6-address 2002:a0b:6566::/0
        end
    next
    edit port2
        set alias ISP
        set allowaccess https ping ssh

```

```
set description "ISP and Internet"
config ipv6
    set ip6-address 2002:AC14:7866::
end
end
```

Configuring RIPng on FortiGate

Now that the interfaces are configured, you can configure RIPng on the FortiGate devices.

There are only two networks and two interfaces to include: the internal network and the ISP network. There is no redistribution and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate as neighbors. This was not part of the previous example as this feature is not offered in the GUI. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the GUI, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI:

```
config router ripng
config interface
    edit port1
    next
    edit port2
end
config neighbor
    edit 1
        set interface port1
        set ipv6 2002:a0b:6566::/0
    next
    edit 2
        set interface port2
        set ipv6 2002:AC14:7805::/0
end
```

To configure RIPng on Router2 - CLI:

```
config router ripng
config interface
    edit port1
    next
    edit port2
end
config neighbor
    edit 1
        set interface port1
        set ipv6 2002:a0b:6565::/0
    next
    edit 2
        set interface port2
        set ipv6 2002:AC14:7805::/0
end
```

Configuring other network devices

The other devices on the internal network all support IPv6 and are running RIPng, where applicable. They only need to know the internal interface network addresses of the FortiGate devices.

The ISP routers need to know the FortiGate information, such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the *Troubleshooting Handbook*.

For troubleshooting problems with RIP, see "[Troubleshooting RIP](#)" on page 2121.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate devices on your network. Comparing the output between devices will help you understand your network better, and also track down any problems:

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate:

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table:

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous `diagnose ipv6 route list` command, but it is presented in a format that is easier to read.

```
get router info6 rip interface external
```

View the brief output on the RIP information for the interface listed. This includes information such as, if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

OSPF

Open Shortest Path First (OSPF) is a link-state interior routing protocol that is widely used in large enterprise organizations. It only routes packets within a single autonomous system (AS). This is different from BGP, because BGP can communicate between ASs.

OSPF version 2 (OSPFv2) was defined in 1998 in [RFC 2328](#). OSPF was designed to support classless IP addressing and variable subnet masks. This was a shortcoming of the earlier RIP protocols.

Updates to OSPFv2 are included in OSPF version 3 (OSPFv3), defined in 2008 in [RFC 5340](#). OSPFv3 includes support for IPv6 addressing, where OSPF2 only supports IPv4 addressing.

The main benefit of OSPF is that it detects link failures in the network quickly and within seconds, has converged network traffic successfully without any networking loops. Also, OSPF has many features to control which routes are propagated and which are not, maintaining smaller routing tables. OSPF can also provide better load-balancing on external links than other interior routing protocols.

The parts and terminology of OSPF

The parts and terminology of OSPF include the following sections.

OSPFv3 and IPv6

OSPF version 3 (OSPFv3) includes support for IPv6. Generally, all IP addresses are in IPv6 format instead of IPv4. However, OSPFv3 area numbers use the same 32-bit numbering system as OSPFv2, as described in [RFC 2740](#). Likewise, the router ID and area ID are in the same format as OSPFv2.

As with most advanced routing features on a FortiGate, IPv6 settings for dynamic routing protocols must be enabled before they are visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Feature Visibility**.

For IPv6, the main difference in OSPFv3 is that rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to the interface and area. This configuration must be done in the CLI, as follows (with sample interfaces and addresses):

```
config router ospf6
  config area
    edit 0.0.0.0
  next
end
config ospf6-interface
  edit "tunnel"
    set interface "to_FGT300A-7"
  next
  edit "internal_lan"
    set interface "port1"
  next
  set router-id 10.174.0.113
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, and neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

Router ID

In OSPF, each router has a unique 32-bit number that is called its router ID. Often, this 32-bit number is written the same as a 32-bit IPv4 address would be written in dotted decimal notation. However, some brands of routers, such as Cisco routers, support a router ID entered as an integer instead of an IP address.

It's a good idea not to use an IP address for the router ID that is already in use on the router. The router ID doesn't have to be a particular IP address on the router. By choosing a different number, it's harder to get confused about which number you're looking at. It's a good idea to use as many of the area's numbers as possible. For example, if you have 15 routers in area 0.0.0.0, they could be numbered from 0.0.0.1 to 0.0.0.15. If you have an area 1.1.1.1, then routers in that area could start at 1.1.1.10.

You can manually set the router ID on a FortiGate:

To manually set an OSPF router ID of 0.0.1.1 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. For **Router ID**, enter 0.0.1.1.
3. Select **Apply**.

To manually set an OSPF router ID of 0.0.1.1 - CLI:

```
config router ospf
  set router-id 0.0.1.1
end
```

Adjacency

In an OSPF routing network, an OSPF router sends out OSPF hello packets when it boots up, to try to find any neighbors (routers that have access to the same network as the router booting up). Once neighbors are discovered and Hello packets are exchanged, updates are sent and the link state databases of both neighbors are synchronized. At this point, these neighbors are said to be adjacent.

For two OSPF routers to become neighbors, the following conditions must be met:

- The subnet mask used on both routers must be the same subnet.
- The subnet number derived using the subnet mask and each router's interface IP address must match.
- The hello interval and the dead interval must match.
- The routers must have the same OSPF area ID. If they're in different areas, they're not neighbors.
- If authentication is used, they must pass authentication checks.

If any of these parameters are different between the two routers, the routers do not become OSPF neighbors and can't be adjacent. If the routers become neighbors, they're adjacent.

Adjacency and neighbors

Neighbor routers can be in a two-way state, and not be adjacent. Adjacent routers normally have a neighbor state of FULL. Neighbors only exchange hello packets and don't exchange routing updates. Adjacent routers exchange LSAs (LSDB information) as well as hello packets. A good example of an adjacent pair of routers is the designated router (DR) and backup designated router (BDR).

You can check on the state of an OSPF neighbor using the CLI `get router info ospf neighbor all` command. For more information, see ["Checking the state of OSPF neighbors" on page 2159](#).

Why adjacency is important

It's important to have adjacent pairs of routers in the OSPF routing domain because routing protocol packets are only passed between adjacent routers. This means adjacency is required for two OSPF routers to exchange routes.

If there's no adjacency between two routers, such as one on the 172.20.120.0 network and another on the 10.11.101.0 network, the routers don't exchange routes. This makes sense because if all OSPF routers on the OSPF domain exchanged updates, it would flood the network.

Also, it's better for updates to progress through adjacent routers to ensure there are no outages along the way. Otherwise, updates could skip over routers that are potentially offline, causing longer routing outages and delays, while the OSPF domain learns of this outage later on.

If the OSPF network has multiple border routers and multiple connections to external networks, the designated router (DR) determines which router pairs become adjacent. The DR can accomplish this because it maintains the complete topology of the OSPF domain, including which router pairs are adjacent.

The backup designated router (BDR) also has this information in case the DR goes offline.

Designated router and backup router

In OSPF, a router can have a number of different roles to play.

A designated router (DR) is the designated broadcasting router interface for an AS. It looks after all of the initial contact and other routing administration traffic. Having only one router do all of this greatly reduces the network traffic and collisions.

If something happens and the designated router goes offline, the backup designated router (BDR) takes over. An OSPF interface on a FortiGate can become either a DR or BDR. Both the DR and the BDR cover the same area and are elected at the same time. The election process doesn't have many rules, but the exceptions can become complex.

Benefits

The OSPF concept of the designated router is a big step above RIP. With all RIP routers doing their own updates all the time, RIP suffers from frequent and sometimes unnecessary updates that can slow down your network. With OSPF, not only do routing changes only happen when a link state changes instead of any tiny change to the routing table, but the designated router reduces this overhead traffic even more.

However, smaller network topologies may have only a couple of routers besides the designated router. This may seem excessive, but it maintains the proper OSPF form and it still reduces the administration traffic, but to a lesser extent than on a large network. Also, your network topology is ready whenever you choose to expand your network.

DR and BDR election

An election chooses DR and BDR from all the available routers. The election is primarily based on the priority setting of the routers, where the highest priority becomes the DR and the second highest becomes the BDR. To resolve any ties, the router with the highest router ID wins. For example, a router with a router ID of 192.168.0.1 would win over a router with a router ID of 10.1.1.2.

The router priority can vary from 0 to 255, but at 0 a router won't become a DR or BDR. If a router with a higher priority comes online after the election, it must wait until the DR and BDR go offline before it becomes the DR.

If the original DR goes offline, but is then available when the BDR goes offline later on, the original DR will be promoted back to DR without an election leaving the new BDR as it is.

With the FortiGate, to configure the port1 interface to be a potential OSPF DR or BDR called `ospf_DR` on the network, you need to raise the priority of the router to a very high number, such as 250 out of 255. This ensures the interface has a chance to be a DR, but won't guarantee that it'll be one. To help ensure it becomes a DR, you should give the interface a low numbered IP address, such as 10.1.1.1 instead of 192.168.1.1 (but that isn't part of this example). Enter the following command:

```
config router ospf
  config ospf-interface
    edit "ospf_DR"
      set priority 250
    next
  end
```

Area

An OSPF area is a smaller part of the larger OSPF AS. Areas are used to limit the link state updates that are sent out. The flooding used for these updates would overwhelm a large network, so it's divided into these smaller areas for manageability.

If there are two or more routers that are viable within an area, there will always be a designated router (DR) and a backup designated router (BDR). For more information about these router roles, see ["Designated router and backup router" on page 2149](#).

Defining a private OSPF area involves the following:

- Assigning a 32-bit number to the area that is unique on your network
- Defining the characteristics of one or more OSPF areas
- Creating associations between the OSPF areas that you defined and the local networks to include in the OSPF area
- Adjusting the settings of OSPF-enabled interfaces, if required

IPv6 OSPF area numbers use the same 32-bit number notation as IPv4 OSPF.

If you are using the GUI to perform these tasks, follow the procedures summarized below.

FortiGate devices support the four main types of OSPF areas: backbone, stub, not-so-stubby, and regular.

Backbone area

Every OSPF network has at least one AS and every OSPF network has a backbone area. The backbone is the main area, and possibly the only area. All other OSPF areas are connected to a backbone area. This means if two areas want to pass routing information back and forth, that routing information will go through the backbone on its way between those areas. For this reason, the backbone not only has to connect to all other areas in the network, but also has to be uninterrupted in order to be able to pass traffic to all points of the network.

The backbone area is referred to as area 0 because it has an IP address of 0.0.0.0.

Stub area

A stub area is an OSPF area that receives no outside routes advertised into it. All routing in it is based on a default route. This essentially isolates it from outside areas.

Stub areas are useful for small networks that are part of a larger organization, especially if the networking equipment can't handle routing large amounts of traffic passing through, or if there are other reasons to prevent outside traffic, such as security. For example, most organizations don't want their accounting department to be the center of their network with everyone's traffic passing through there. It increases the security risks, slows down the network, and it generally doesn't make sense.

A variation on the stub area is the totally stubby area. It's a stub area that doesn't allow summarized routes.

NSSA

A not-so-stubby-area (NSSA) is a stub area that allows for external routes to be injected into it. While it still doesn't allow routes from external areas, it's not limited to using only the default route for internal routing.

Regular area

A regular area is what all the other ASs are, all the non-backbone, non-stub, and non-NSSA areas. A regular area generally has a connection to the backbone, does receive advertisements of outside routes, and doesn't have an area number of 0.0.0.0.

Authentication

In the OSPF packet header, there are two authentication-related fields: AuType and Authentication.

All OSPF packet traffic is authenticated. Multiple types of authentication are supported in OSPFv2. However, in OSPFv3, there's no authentication built-in but it's assumed that IPsec is used for authentication instead.

Packets that fail authentication are discarded.

Null authentication

Null authentication indicates there's no authentication being used. In this case, the 16-byte authentication field isn't checked, and can be any value. However, checksumming is still used to locate errors. On a FortiGate, this is the `none` option for authentication.

Simple password authentication

Simple password refers to a standard plain text string of characters. The same password is used for all transactions on a network. The main use for this type of authentication is to prevent routers from accidentally joining the network. Simple password authentication is vulnerable to many forms of attack, and isn't recommended as a secure form of authentication.

Cryptographic authentication

Cryptographic authentication involves the use of a shared secret key to authenticate all router traffic on a network. The key is never sent over the network in the clear. A packet is sent and a condensed and encrypted form of the packet is appended to the end of the packet. A non-repeating sequence number is included in the OSPF packet to protect against replay attacks that could try to use already sent packets to disrupt the network. When a packet is accepted as authentic, the authentication sequence number is set to the packet sequence number. If a replay attack is attempted, the packet sent will be out of sequence and ignored.

A FortiGate supports all three levels of authentication through the authentication keyword associated with creating an OSPF interface .

For example, to create an OSPF interface called `Accounting` on the port1 interface that is a broadcast interface, has a hello interval of 10 seconds, has a dead interval of 40 seconds, uses text authentication (simple password) with a password of "ospf_test", enter the following CLI commands:

```
config router ospf
  config ospf-interface
    edit Accounting
      set interface port1
      set network-type broadcast
      set hello-interval 10
      set dead-interval 40
      set authentication text
      set authentication-key ospf_test
    next
  end
```

Hello and dead intervals

The OSPF Hello protocol is used to discover and maintain communications with neighboring routers.

Hello packets are sent out at a regular interval for this purpose. The DR sends out the hello packets. In a broadcast network, the multicast address of 224.0.0.5 is used to send out hello packets. New routers on the network listen for and reply to these packets to join the OSPF area. If a new router never receives a hello packet, other routers won't know it is there and won't communicate with it. However, once a new router is discovered, the DR adds it to the list of routers in that area and it's integrated into the routing calculations.

Dead interval is the time other routers wait before declaring a neighbor dead (offline). It's very important to set a reasonable dead interval. If this interval is too short, routers will be declared offline when they are just slow or momentarily inaccessible, and link state updates will happen more than they need to, using more bandwidth. If the dead interval is too long, it will slow down network traffic overall if online routers attempt to contact offline ones instead of re-routing traffic.

FortiOS also supports OSPF fast-hello, which provides a way to send multiple hello packets per second. This is achieved by setting a dead-interval to one second. The hello-multiplier, which can be any number between 4 and 10, determines the number of hello packets that will be sent every second. The CLI syntax for OSPF fast-hello is the following:

```
config ospf-interface
edit ospf1
set interface port1
set network-type broadcast
set dead-interval 1
set hello-multiplier 4
next
end
```

Access lists

Access lists are filters used by OSPF routing on a FortiGate. An access list provides a list of IP addresses and the action to take for them. An access list essentially makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example, if you want all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate attempts to match a packet against the rules in an access list, starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found, the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. It also eases troubleshooting because if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the OSPF+ IPv6 protocols, you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of 10.10.10.10 and 11.11.11.11, enter the following CLI commands:

```
config router access-list
```

```

edit test_list
config rule
edit 1
set prefix 10.10.10.10 255.255.255.255
set action allow
set exact-match enable
next
edit 2
set prefix 11.11.11.11 255.255.255.255
set action allow
set exact-match enable
next
next
end

```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the following `access-list6` CLI commands:

```

config router access-list6
edit test_list_ip6
config rule
edit 1
set prefix6 2002:A0A:A0A:0:0:0:0:0/48
set action deny
next
edit 2
set prefix6 2002:B0B:B0B:0:0:0:0:0/48
set action deny
next
next
end

```

To use an `access_list`, you must call it from a routing protocol such as RIP. The following example uses the `access_list` from the earlier example called `test_list` to match routes coming in on the `port1` interface. When there's a match, it'll add 3 to the hop count metric for those routes to artificially decrease their priority. Enter the following CLI commands:

```

config router ospf
config distribute-list
edit 5
set access-list test_list
set protocol connected
next
end

```

If you're setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route 0.0.0.0/0 can't be matched exactly with an `access-list`. A `prefix-list` must be used for this purpose.

How OSPF works

An OSPF installation consists of one or more areas. An OSPF area is typically divided into logical areas linked by Area Border Routers (ABR). A group of contiguous networks form an area. An ABR links one or more areas to the OSPF network backbone (area ID 0). For more information, see ["Dynamic routing" on page 2093](#).

OSPF is an interior routing protocol. It includes a backbone AS and possibly additional ASs. The DR and BDR are elected from potential routers with the highest priorities. The DR handles much of the administration to lower the

network traffic required. New routers are discovered through hello packets sent from the DR using the multicast address of 224.0.0.5. If the DR goes offline at any time, the BDR has a complete table of routes that it uses when it takes over as the DR router.

OSPF doesn't use UDP or TCP, but is encapsulated directly in IP datagrams as protocol 89. This is in contrast to RIP and BGP. OSPF handles its own error detection and correction functions.

The OSPF protocol, when running on IPv4, can operate securely between routers, optionally using a variety of authentication methods to allow only trusted routers to participate in routing. OSPFv3, running on IPv6, no longer supports protocol-internal authentication. Instead, it relies on IPv6 protocol security (IPsec).

Other important parts of how OSPF works include:

- [OSPF router discovery](#)
- [How OSPF works on FortiGate devices](#)
- [External routes](#)
- [Link state database and route updates](#)
- [OSPF packets](#)

OSPF router discovery

OSPF-enabled routers generate link state advertisements (LSA) and send them to their neighbors whenever the status of a neighbor changes or a new neighbor comes online. As long as the OSPF network is stable, LSAs between OSPF neighbors don't occur. An LSA identifies the interfaces of all OSPF-enabled routers in an area, and provides information that enables OSPF-enabled routers to select the shortest path to a destination. All LSA exchanges between OSPF-enabled routers are authenticated.

When a network of OSPF routers comes online, the following steps occur:

1. When OSPF routers come online, they send out hello packets to find other OSPF routers on their network segment.
2. When they discover other routers on their network segment, they generally become adjacent. Adjacent routers can exchange routing updates. For more information, see ["Adjacency" on page 2148](#).
3. A DR and BDR are elected from the available routers using priority settings and router ID. See ["Designated router and backup router" on page 2149](#), and ["DR and BDR election issues" on page 2160](#).
4. Link state updates are sent between adjacent routers to map the topology of the OSPF area.
5. Once complete, the DR floods the network with the updates to ensure all OSPF routers in the area have the same OSPF route database. After the initial update, there are very few required updates if the network is stable.

How OSPF works on FortiGate devices

When a FortiGate interface is connected to an OSPF area, that unit can participate in OSPF communications. FortiGate devices use the OSPF hello protocol to acquire neighbors in an area. A neighbor is any router that's directly connected to the same area as the FortiGate and is ideally adjacent with a state of Full. After initial contact, the FortiGate exchanges hello packets with its OSPF neighbors regularly to confirm that the neighbors can be reached.

The number of routes that a FortiGate can learn through OSPF depends on the network topology. A single unit can support tens of thousands of routes if the OSPF network is configured properly.

External routes

OSPF is an internal routing protocol. OSPF external routes are routes where the destination is using a routing protocol other than OSPF. OSPF handles external routes by adjusting the cost of the route to include the cost of the other routing protocol. There are two methods of calculating this cost, which are used for OSPF external1 (E1) and OSPF external2 (E2).

OSPF E1

In OSPF E1, the destination is outside the OSPF domain. This requires a different metric to be used beyond the normal OSPF metrics. The new metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.

OSPF E2

OSPF E2 is the default external type when routes are redistributed outside of OSPF. With OSPF E2, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. Dropping the OSPF portion can be useful in a number of situations, for example, on border routers that have no OSPF portion or where the OSPF routing cost is negligible compared to the external routing cost.

Comparing E1 and E2

The best way to understand OSPF E1 and E2 routes is to check routing tables on OSPF routers. If you look at the routes on an OSPF border router, the redistributed routes will have an associated cost that represents only the external route, as there is no OSPF cost to the route due to it already being on the edge of the OSPF domain. However, if you look at that same route on a different OSPF router inside the OSPF routing domain, it has a higher associated cost, essentially the external cost plus the cost over the OSPF domain to that border router. The border router uses OSPF E2, where the internal OSPF router uses OSPF E1 for the same route.

Viewing external routes

When you're trying to determine the costs for routes in your network to predict how traffic will be routed, you need to see the external OSPF routes and their associated costs. On a FortiGate, you can use the CLI to find this information.

To view external routes - CLI:

You can view the whole routing table using the `get router info routing-table all` command to see all of the routes, including the OSPF external routes. To view a shorter list, you can use the `get router info routing-table ospf` command. The letter at the left will be either E1 or E2 for external OSPF routes. The output looks similar to the following, depending on what routes are in the routing table:

```
FGT620B# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

O*E2   0.0.0.0/0 [110/10] via 10.1.1.3, tunnel_wan2, 00:02:11
O      10.0.0.1/32 [110/300] via 10.1.1.3, tunnel_wan2, 00:02:11
S      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S      1.0.0.0/8 [10/0] via 192.168.183.254, port2
```

Link state database and route updates

OSPF is based on links. The links between adjacent neighbor routers allow updates to be passed along the network. Network links allow the DR to flood the area with link state database (LSDB) updates. External links allow the OSPF area to connect to destinations outside the OSPF autonomous system. Information about these links is passed throughout the OSPF network as link state updates.

The LSDB contains the information that defines the complete OSPF area, but the LSDB isn't the routing table. It contains the information from all the link state updates passed along the network. When there are no more changes required and the network is stable, the LSDB on each router in the network is the same. The DR floods the LSDB to the area to ensure that each router has the same LSDB.

To calculate the best route (shortest path) to a destination, the FortiGate applies the Shortest Path First (SPF) algorithm, based on Dijkstra's algorithm, to the accumulated link state information. OSPF uses relative path cost metric for choosing the best route. The path cost can be any metric, but it's typically the bandwidth of the path, which is how fast traffic will get from one point to another.

The path cost, similar to distance for RIP, imposes a penalty on the outgoing direction of a FortiGate interface. The path cost of a route is calculated by adding all of the costs associated with the outgoing interfaces along the path to the destination. The lowest overall path cost indicates the best route, and generally the fastest route. Some brands of OSPF routers, such as Cisco, implement cost as a direct result of bandwidth between the routers. Generally this is a good cost metric because larger bandwidth means more traffic can travel without slowing down. To achieve this type of cost metric on FortiGate devices, you need to set the cost for each interface manually in the CLI.

The inter-area routes may not be calculated when a Cisco type ABR has no fully adjacent neighbor in the backbone area. In this situation, the router considers summary-LSAs from all Actively summary-LSAs from all Actively Attached areas ([RFC 3509](#)).

The FortiGate dynamically updates its routing table based on the results of the SPF calculation to ensure that an OSPF packet will be routed using the shortest path to its destination. Depending on the network topology, the entries in the FortiGate routing table may include:

- The addresses of networks in the local OSPF area (to which packets are sent directly)
- Routes to OSPF area border routers (to which packets destined for another area are sent)
- Routes to area boundary routers, if the network contains OSPF areas and non-OSPF domains, which reside on the OSPF network backbone and are configured to forward packets to destinations outside the OSPF AS.

OSPF route updates

Once the OSPF domain is established, there should be few updates required on a stable network. When updates occur and a decision is required concerning a new route, this is the general procedure.

Our router gets a new route and needs to decide if it should go in the routing table.

The router has an up-to-date LSDB of the entire area, containing information about each router, the next hop to it, and most importantly the cost to get there.

Our router turns the LSDB into an SPF tree using Dijkstra's algorithm. It doesn't matter if there's more than one path to a router on the network, the SPF tree only cares about the shortest path to that router.

Once the SPF tree has been created and shows the shortest paths to all the OSPF routers on the network, the work is done. If the new route is the best route, it'll be part of that tree. If it's not the shortest route, it won't be included in the LSDB.

If there has been a change from the initial LSDB to the new SPF tree, a link state update will be sent out to let the other routers know about the change so they can also update their LSDBs. This is vital since all routers on the OSPF area must have the same LSDB.

If there was no change between the LSDB and the SPF tree, no action is taken.

OSPF packets

Every OSPF packet starts with a standard 24-byte header, and another 24 bytes of information or more. The header contains all the information necessary to determine whether the packet should be accepted for further processing.

OSPF packet

1-byte Version field	1-byte Type field	2-byte Packet length	3-byte Router ID
4-byte Area ID	2-byte Checksum	2-byte Auth Type	8-byte Authentication
4-byte Network Mask	2-byte Hello interval	1-byte Options field	1-byte Router Priority
4-byte Dead Router interval	4-byte DR field	4-byte BDR field	4-byte Neighbor ID

The following descriptions summarize the OSPF packet header fields:

Version field: The OSPF version number. This specification documents version 2 of the protocol.

Type field: There are 5 OSPF packet types. From one to five, respectively, they are Hello, Database Description, Link State Request, Link State Update, and Link State Acknowledgment.

Packet length: The length of the OSPF protocol packet, in bytes. This length includes the standard OSPF 24-byte header, so all OSPF packets are at 24-bytes long.

Router ID: The Router ID of the packet's source.

Area ID: A 32-bit number identifying the area that this packet belongs to. All OSPF packets are associated with a single area. Most travel a single hop only. Packets travelling over a virtual link are labelled with the backbone Area ID of 0.0.0.0.

Checksum: The standard IP checksum of the entire contents of the packet, starting with the OSPF packet header but excluding the 64-bit authentication field. This checksum is calculated as the 16-bit one's complement of the one's complement sum of all the 16-bit words in the packet, excepting the authentication field. If the packet's length isn't an integral number of 16-bit words, the packet is padded with a byte of zero before checksumming. The checksum is considered to be part of the packet authentication procedure. For some authentication types, the checksum calculation is omitted.

Auth Type: Identifies the authentication procedure to be used for the packet. Authentication types include Null authentication (0), Simple password (1), Cryptographic authentication (2), and all others are reserved for future use.

Authentication: A 64-bit field for use by the authentication scheme. When AuType indicates no authentication is being used, the authentication field isn't checked and can be any value. When AuType is set to 2 (cryptographic authentication), the 64-bit authentication field is split into the following four fields: Zero field, Key ID field, Authentication data length field, and Cryptographic sequence field.

The Key ID field indicates the key and algorithm used to create the message digest appended to the packet. The Authentication data length field indicates how many bytes long the message digest is. The Cryptographic sequence field is a non-decreasing number that is set when the packet is received and authenticated to prevent replay attacks.

Network Mask: The subnet where this packet is valid.

Hello interval: The period of time between sending out hello packets. For more information, see ["Hello and dead intervals" on page 2152](#).

Options field: The OSPF protocol defines several optional capabilities. A router indicates the optional capabilities that it supports in its OSPF hello packets, database description packets and in its LSAs. This enables routers supporting a mix of optional capabilities to coexist in a single AS.

Router priority: The priority, between 0 and 255, that determines which routers become the DR and BDR. For more information, see ["Designated router and backup router" on page 2149](#).

Dead router interval: The period of time when there's no response from a router before it's declared dead. For more information, see ["Hello and dead intervals" on page 2152](#).

DR and BDR fields: The DR and BDR fields each list the router that fills that role on this network, generally the routers with the highest priorities. For more information, see ["Designated router and backup router" on page 2149](#).

Neighbor ID: The ID number of a neighboring router. This ID is used to discover new routers and respond to them.

OSPF and VRFs

You can configure OSPF support for multiple virtual routing and forwarding (VRFs) on a FortiGate.

To add VRFs for interfaces - CLI:

```
config system interface
  edit <name>
    set vrf <VRF ID>
  next
end
```

where `vrf` is a value of 0 to 31.

Troubleshooting OSPF

As with other dynamic routing protocols, OSPF has some issues that may need troubleshooting from time to time. For basic troubleshooting, see the *Troubleshooting Handbook*.

Clearing OSPF routes from the routing table

If you think the wrong route has been added to your routing table and you want to check it out, you first have to remove that route from your table before seeing if it's added back in or not. You can clear all or some OSPF neighbor connections (sessions) using the `execute router clear ospf` CLI command. The `exec`

`router clear` command is much more limiting for OSPF than it is for BGP. For more information, see ["BGP" on page 2187](#).

For example, if you have routes in the OSPF routing table and you want to clear the specific route to IP address 10.10.10.1, you'll have to clear all the OSPF entries. Enter the following CLI command:

```
execute router clear ospf process
```

Checking the state of OSPF neighbors

In OSPF, each router sends out link state advertisements to find other routers on its network segment and to create adjacencies with some of those routers. This is important because routing updates are only passed between adjacent routers. If two routers you believe to be adjacent are not, that can be the source of routing failures.

To identify this problem, you need to check the state of the OSPF neighbors of the FortiGate. Use the `get router info ospf neighbor all` CLI command to see all the neighbors for the FortiGate. You'll see output in the form of the following:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID  Pri  State      Dead Time Address Interface
10.0.0.2      1   Full/ -   00:00:39 10.1.1.2 tunnel_wan1
10.0.0.2      1   Full/ -   00:00:34 10.1.1.4 tunnel_wan2
```

The important information here is the `State` column. Any neighbors that are not adjacent to the FortiGate are reported in this column as something other than `Full`. If the state is `Down`, that router is offline.

Passive interface problems

A passive OSPF interface doesn't send out any updates. This means it can't be a DR, BDR, or an area border router among other things. It depends on other neighbor routers to update its link state table.

Passive interfaces can cause problems when they're not receiving the routing updates you expect from their neighbors. This results in the passive OSPF interface on the FortiGate having an incomplete or out-of-date link state database, and it won't be able to properly route its traffic. It's possible that the passive interface is causing a hole in the network where no routers are passing updates to each other, however, this is a rare situation.

If a passive interface is causing problems, there are simple methods to determine it's the cause. The easiest method is to make it an active interface, and if the issues disappear, then that was the cause. Another method is to examine the OSPF routing table and related information to see if it's incomplete compared to other neighbor routers. If this is the case, you can clear the routing table, reset the device, and allow it to repopulate the table.

If you can't make the interface active for some reason, you have to change your network to fix the hole by adding more routers, or changing the relationship between the passive router's neighbors to provide better coverage.

Timer problems

A timer mismatch is when two routers have different values set for the same timer. For example, if one router declares a router dead after 45 seconds and another waits for 4 minutes, that difference in time results in the two routers being out of synch for that period of time. One will still see the offline router as being online.

The easiest method to check the timers is to check the configuration on each router. Another method is to sniff some packets, and read the timer values in the packets themselves from different routers. Each packet contains the hello interval and dead interval periods, so you can compare them easily enough.

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD communicate with each other and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated. For more information about BFD, see ["BFD" on page 2106](#).

Authentication issues

OSPF has a number of authentication methods you can choose from. You may encounter problems with routers not authenticating as you expect. This will likely appear simply as one or more routers that have a blind spot in their routing and they won't acknowledge a router. This can be a problem if that router connects areas to the backbone, as it'll appear to be offline and unusable.

To confirm this is the issue, the easiest method is to turn off authentication on the neighboring routers. With no authentication between any routers, everything should flow normally.

Another method to confirm that authentication is the problem is to sniff packets and look at their contents. The authentication type and password are right in the packets which makes it easy to confirm they are what you expect during real time. It's possible that one or more routers isn't configured as you expect and may be using the wrong authentication. This method is especially useful if there are a group of routers with these problems since it may be only one router causing the problem that's seen in multiple routers.

Once you have confirmed the problem is related to authentication, you can decide how to handle it. You can turn off authentication and take your time to determine how to get your preferred authentication type back online. You can try another type of authentication, such as text instead of md5, which may have more success and still provide some level of protection. The important part is that once you confirm the problem, you can decide how to fix it properly.

DR and BDR election issues

You can force a particular router to become the DR and BDR by setting its priorities higher than any other OSPF routers in the area. This is a good idea when those routers have more resources to handle the traffic and extra work of the DR and BDR roles, since not all routers may be able to handle all of that traffic.

However, if you set all the other routers so they don't have a chance at being elected (give them a priority of 0), you can run into problems if the DR and BDR go offline. The good part is that you'll have some warning generally as the DR goes offline and the BDR is promoted to the DR position. However, if the network segment with both the DR and BDR goes down, your network won't have a way to send hello packets, send updates, or perform the other tasks that the DR performs.

The solution to this is to always allow routers to have a chance to be promoted, even if you set their priority to 1. In that case, they'll be the last choice but if there are no other candidates, you want that router to become the DR. Most networks will have already alerted you to the equipment problems, so this will be a temporary measure to keep the network traffic moving until you can find and fix the problem and get the real DR back online.

Basic OSPF example

This example sets up an OSPF network at a small office. There are 3 routers, all running OSPFv2. The border router connects to a BGP network.

All three routers in this example are FortiGate devices. Router1 will be the designated router (DR) and Router2 will be the backup designated router (BDR) due to their priorities. Router3 won't be considered for either the DR or

BDR elections. Instead, Router3 is the Autonomous System Border Router (ASBR) routing all traffic to the ISP's BGP router on its way to the Internet.

Router2 has a modem connected that provides dialup access to the Internet as well, at a reduced bandwidth. This is a PPPoE connection to a DSL modem. This provides an alternate route to the Internet if the other route goes down. The DSL connection is slow and is charged by the amount of traffic. For these reasons, OSPF will highly favor Router3's Internet access.

The DSL connection connects to an OSPF network with the ISP, so no redistribution of routes is required. However, the ISP network does have to be added to that router's configuration.

Network layout and assumptions

There are three FortiGate devices acting as OSPFv2 routers on the network: Router1, Router2, and Router3. Router1 will be the DR, and Router 2 the BDR. Router3 is the ASBR that connects to the external ISP router running BGP. Router2 has a PPPoE DSL connection that can access the Internet.

The head office network is connected to Router1 and Router2 on the 10.11.101.0 subnet.

Router1 and Router3 are connected over the 10.11.103.0 subnet.

Router2 and Router3 are connected over the 10.11.102.0 subnet.

The following table lists the router, interface, address, and role it's assigned.

Routers, interfaces, and IP addresses for the basic OSPF example network

Router name	Interface	IP address	Interface is connected to:
Router1 (DR)	Internal (port1)	10.11.101.1	Head office network and Router2
	External (port2)	10.11.102.1	Router3
Router2 (BDR)	Internal (port1)	10.11.101.2	Head office network and Router1
	External (port2)	10.11.103.2	Router3
	DSL (port3)	10.12.101.2	PPPoE DSL access
	Internal1 (port1)	10.11.102.3	Router1
Router3 (ASBR)	Internal2 (port2)	10.11.103.3	Router2
	External (port3)	172.20.120.3	ISP's BGP network

Basic OSPF network topology

Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate devices used in this example have interfaces named port1, port2, and port3.
- All FortiGate devices in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed and are in NAT/Route operation mode.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF networks.
- Both Internet connections are always available.
- The modem connection is very slow and expensive.
- Other devices may be on the network, but do not affect this basic configuration.
- Router3 is responsible for redistributing all routes into and out of the OSPF AS.

Configuring the FortiGate devices

Each FortiGate needs the interfaces and basic system information, such as hostname, configured.

Configuring Router1

Router1 has two interfaces connected to the network: internal (port1) and external (port2). Its host name must be changed to Router1.

To configure Router1 interfaces - GUI:

1. Go to **System > Dashboard > Status**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router1` and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router2
Administrative Status	Up

5. Edit port2, set the following information and select **OK**.

Alias	External
IP/Network Mask	10.11.102.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

Configuring Router2

Router2 configuration is the same as Router1, except Router2 also has the DSL interface to configure.

The DSL interface is configured with a username of “user1” and a password of “ospf_example”. The default gateway is retrieved from the ISP and the defaults are used for the rest of the PPPoE settings.

To configure Router2 interfaces - GUI:

1. Go to **System > Dashboard > Status**.
2. Beside the host name, select **Change**.
3. Enter a hostname of `Router2` and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router1

Administrative Status	Up
------------------------------	----

5. Edit port2, set the following information and select **OK**.

Alias	External
IP/Network Mask	10.11.103.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

6. Edit DSL (port3), set the following information and select **OK**.

Alias	DSL
Addressing Mode	PPPoE
Username	user1
Password	ospf_example
Unnumbered IP	10.12.101.2/255.255.255.0
Retrieve default gateway from server	Enable
Administrative Access	HTTPS SSH PING
Description	DSL
Administrative Status	Up

Configuring Router3

Router3 is similar to Router1 and Router2 configurations. The main difference is the External (port3) interface connected to the ISP BGP network, which has no administration access enabled, for security reasons.

To configure Router3 interfaces - GUI:

1. Go to **System > Status > Dashboard**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3` and select **OK**.
4. Go to **Network > Interfaces**, edit port1, set the following information, and select **OK**.

Alias	internal
--------------	----------

IP/Network Mask	10.11.102.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router1
Administrative Status	Up

5. Edit port2, set the following information and select **OK**.

Alias	Internal2
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2
Administrative Status	Up

6. Edit port3, set the following information and select **OK**.

Alias	External
IP/Network Mask	172.20.120.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP BGP
Administrative Status	Up

Configuring OSPF on the FortiGate devices

With the interfaces configured, now the FortiGate devices can be configured for OSPF on those interfaces. All routers are part of the backbone 0.0.0.0 area, so no inter-area communications are needed.

For a simple configuration, there will be no authentication, no graceful restart or other advanced features, and timers will be left at their defaults. Also, the costs for all interfaces will be left at 10, except for the modem and ISP interfaces where cost will be used to load balance traffic. Nearly all advanced features of OSPF are only available from the CLI.

The network that's defined covers all the subnets used in this example - 10.11.101.0, 10.11.102.0, and 10.11.103.0. All routes for these subnets will be advertised. If there are other interfaces on the FortiGate devices that you don't want included in the OSPF routes, ensure those interfaces use a different subnet outside of the 10.11.0.0 network. If you want all interfaces to be advertised you can use an OSPF network of 0.0.0.0 .

Each router will configure:

- Router ID
- Area

- Network
- Two or three interfaces depending on the router
- Priority for DR (Router1) and BDR (Router2)
- Redistribute for ASBR (Router3)

Configuring OSPF on Router1

Router1 has a very high priority to ensure it becomes the DR for this area. Also Router1 has the lowest IP address to help ensure it will win in case there's a tie at some point. Otherwise, it's a standard OSPF configuration. Setting the priority can only be done in the CLI, and it's for a specific OSPF interface.

To configure OSPF on Router1 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.1` and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router1-Internal-DR
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router1-External
-------------	------------------

Interface	port2 (External)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

7. Using the CLI, enter the following commands to set the priority for the Router1-Internal OSPF interface to maximum, ensuring this interface becomes the DR:

```
config router ospf
  config ospf-interface
    edit Router1-Internal-DR
      set priority 255
    next
  end
```

To configure OSPF on Router1 - CLI:

```
config router ospf
  set router-id 10.11.101.1
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.255.0
    next
  end
  config ospf-interface
    edit "Router1-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router1-External"
      set interface "port2"
    next
  end
end
```

Configuring OSPF on Router2

Router2 has a high priority to ensure it becomes the BDR for this area and configures the DSL interface slightly differently. Assume this will be a slower connection resulting in the need for longer timers and a higher cost for this route.

Otherwise, it is a standard OSPF configuration.

To configure OSPF on Router2 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router2-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router2-External
Interface	port2 (External)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router2-DSL
Interface	port3 (DSL)
IP	0.0.0.0
Authentication	none
Cost	50
Timers (seconds)	
Hello Interval	20
Dead Interval	80

8. Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR:

```
config router ospf
  config ospf-interface
    edit Router2-Internal
      set priority 250
    next
  end
```

To configure OSPF on Router2 - CLI:

```
config router ospf
  set router-id 10.11.101.2
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.0.0
    next
  end
  config ospf-interface
    edit "Router2-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router2-External"
      set interface "port2"
    next
    edit "Router2-DSL"
      set interface "port3"
      set cost 50
    next
  end
end
```

Configuring OSPF on Router3

Router3 is more complex than the other two routers. The interfaces are straightforward, but this router has to import and export routes between OSPF and BGP. That requirement makes Router3 an ASBR. Also, Router3 needs a lower cost on its route to encourage all traffic to the Internet to route through it.

In the advanced OSPF options, redistribute is enabled for Router3. It allows different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics are assigned to these other types of routes to make them more or less preferred to regular OSPF routes.

To configure OSPF on Router3 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. Set **Router ID** to `10.11.101.2` and select **Apply**.
3. Expand **Advanced Options**.
4. In **Redistribute**, set the following information, and select **OK**.

Route type	Redistribute	Metric
Connected	Enable	15
Static	Enable	15
RIP	Disable	n/a
BGP	Enable	5

5. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	none

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Router3-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none

Timers (seconds)**Hello Interval** 10**Dead Interval** 40

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name Router3-Internal2**Interface** port2 (Internal2)**IP** 0.0.0.0**Authentication** none**Timers (seconds)****Hello Interval** 10**Dead Interval** 40

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name Router3-ISP-BGP**Interface** port3 (ISP-BGP)**IP** 0.0.0.0**Authentication** none**Cost** 2**Timers (seconds)****Hello Interval** 20**Dead Interval** 80

10. Using the CLI, enter the following commands to set the priority for the Router3-Internal OSPF interface to ensure this interface will become the BDR:

```
config router ospf
  config ospf-interface
    edit Router3-Internal
      set priority 250
    next
  end
```

To configure OSPF on Router3 - CLI:

```
config router ospf
  set router-id 10.11.102.3
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.255.0
    next
    edit 2
      set prefix 172.20.120.0/255.255.255.0
    next
  end
  config ospf-interface
    edit "Router3-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router3-External"
      set interface "port2"
    next
    edit "Router3-ISP-BGP"
      set interface "port3"
      set cost 2
    next
  end
end
```

Configuring other networking devices

The other networking devices required in this configuration are on the two ISP networks, the BGP network for the main Internet connection, and the DSL backup connection.

In both cases, the ISPs need to be notified about the OSPF network settings including router IP addresses, timer settings, and so on. The ISP will use this information to configure its routers that connect to this OSPF network.

Testing network configuration

Testing the network configuration involves two parts: testing the network connectivity and testing the OSPF routing.

To test the network connectivity, use ping, traceroute, and other network tools.

To test the OSPF routing in this example, refer to the troubleshooting outlined in ["Troubleshooting OSPF" on page 2158](#).

Advanced inter-area OSPF example

This example sets up an OSPF network at a large office. There are three areas, each with two routers. Typically OSPF areas wouldn't be this small, and if they were, the areas would be combined into one larger area. However, the stub area services the accounting department whose members are very sensitive about their network and don't want their network information broadcasted through the rest of the company. The backbone area contains

the bulk of the company's network devices. The regular area was established for various reasons, such as hosting the company servers in a separate area with extra security.

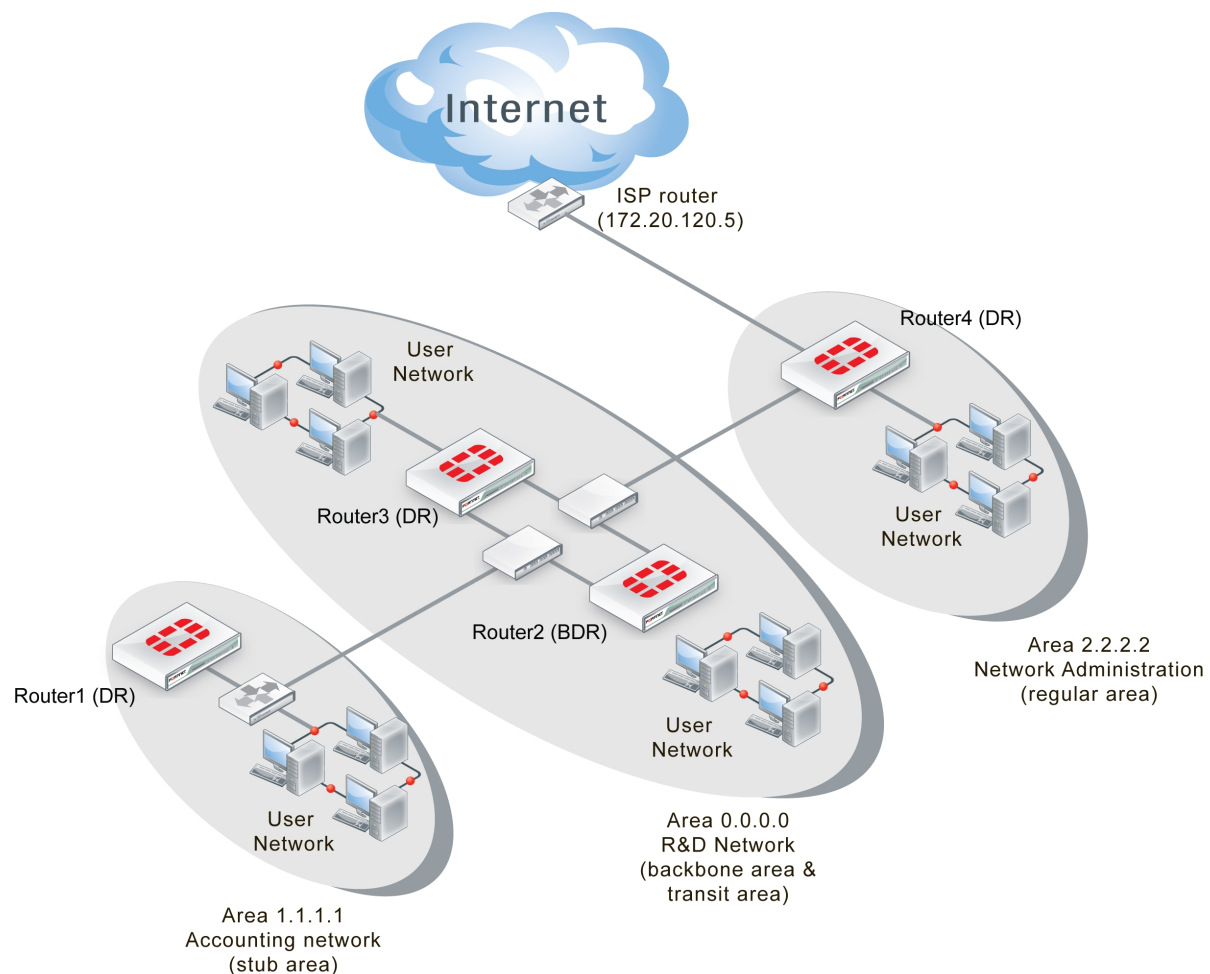

One area is a small stub area that has no independent Internet connection, and has only one connection to the backbone area. That connection between the stub area and the backbone area is only through a default route. No routes outside the stub area are advertised into that area. Another area is the backbone, which is connected to the other two areas. The third area has the Internet connection, and all traffic to and from the Internet must use that area's connection. If that traffic comes from the stub area, then that traffic is treating the backbone like a transit area that only uses it to get to another area.

In the stub area, a subnet of computers is running the RIP routing protocol and those routes must be redistributed into the OSPF areas.

Network layout and assumptions

There are four FortiGate devices in this network topology, which are acting as OSPF routers:

Advanced inter-area OSPF network topology

Area 1.1.1.1 is a stub area with one FortiGate OSPF router called Router1 (DR). Its only access outside of that area is a default route to the backbone area, which is how it accesses the Internet. Traffic must go from the stub area, through the backbone, to the third area to reach the Internet. The backbone area in this configuration is

called a transit area. Also, in area 1.1.1.1 there is a RIP router that will be providing routes to the OSPF area through redistribution.

Area 0.0.0.0 is the backbone area and has two FortiGate device routers named Router2 (BDR) and Router3 (DR).

Area 2.2.2.2 is a regular area that has an Internet connection accessed by both the other two OSPF areas. There is only one FortiGate device router in this area called Router4 (DR). This area is more secure and requires MD5 authentication by routers.

All areas have user networks connected but they're not important for configuring the network layout for this example.

Internal interfaces are connected to internal user networks only. External1 interfaces are connected to the 10.11.110.0 network, joining Area 1.1.1.1 and Area 0.0.0.0.

External2 interfaces are connected to the 10.11.111.0 network, joining Area 0.0.0.0 and Area 2.2.2.2. The ISP interface is called ISP.

Routers, areas, interfaces, and IP addresses for advanced OSPF network

Router name	Area number and type	Interface	IP address
Router1 (DR)	1.1.1.1 - stub area (Accounting)	port1 (internal)	10.11.101.1
		port2 (external1)	10.11.110.1
Router2 (BDR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.102.2
		port2 (external1)	10.11.110.2
		port3 (external2)	10.11.111.2
Router3 (DR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.103.3
		port2 (external1)	10.11.110.3
		port3 (external2)	10.11.111.3
Router4 (DR)	2.2.2.2 - regular area (Network Admin)	port1 (internal)	10.11.104.4
		port2 (external2)	10.11.111.4
		port3 (ISP)	172.20.120.4

Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate devices used in this example have interfaces named port1, port2, and port3.
- All FortiGate devices in this example have factory default configuration with FortiOS 4.0 MR2 firmware installed and are in NAT/Route operation mode.
- During configuration, if settings are not directly referred to, they will be left at the default settings.

- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF areas outside of this example.
- The Internet connection is always available.
- Other devices may be on the network but do not affect this configuration.

Configuring the FortiGate devices

This section configures the basic settings on the FortiGate devices to be OSPF routers. These configurations include multiple interface settings and the hostname.

There are four FortiGate devices in this example. The two devices in the backbone area can be configured exactly the same except for IP addresses, so only the Router3 (the DR) configuration will be given, with notes indicating Router2's (the BDR) IP addresses.

Configuring the FortiGate devices includes:

- [Configuring Router1](#)
- [Configuring Router2](#)
- [Configuring Router3](#)
- [Configuring Router4](#)

Configuring Router1

Router1 is part of the Accounting network stub area (1.1.1.1).

To configure Router1 interfaces - GUI:

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router1` and select **OK**.
4. Go to **Network > Interfaces** edit port1, set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

5. Edit port2, set the following information and select **OK**.

Alias	External1
IP/Network Mask	10.11.110.1/255.255.255.0
Administrative Access	HTTPS SSH PING

Description	Backbone network and Internet
Administrative Status	Up

Configuring Router2

Router2 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

Router2 has three interfaces configured: one to the internal network and two to Router3 for redundancy.

To configure Router2 interfaces - GUI:

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router2` and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.102.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 second connection

Administrative Status	Up
------------------------------	----

Configuring Router3

Router3 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

To configure Router3 interfaces - GUI:

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router3` and select **OK**.
4. Go to **Network > Interfaces**, edit port1 (internal), set the following information, and select **OK**.

Alias	internal
IP/Network Mask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information and select **OK**.

Alias	external1
IP/Network Mask	10.11.110.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information and select **OK**.

Alias	external2
IP/Network Mask	10.11.111.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 second connection
Administrative Status	Up

Configuring Router4

Router4 is part of the Network Administration regular area (2.2.2.2). This area provides Internet access for both area 1.1.1.1 and the backbone area.

This section configures interfaces and hostname.

To configure Router4 interfaces - GUI:

1. Go to **System > Dashboard > Status**.
2. Next to hostname, select **Change**.
3. Enter a hostname of `Router4` and select **OK**.
4. Go to **Network > Interfaces**.
5. Edit port1 (internal).
6. Set the following information and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

7. Edit port2 (external2).
8. Set the following information and select **OK**.

Alias	external2
IP/Network Mask	10.11.110.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone and Accounting network
Administrative Status	Up

9. Edit port3 (ISP).
10. Set the following information and select **OK**.

Alias	ISP
IP/Network Mask	172.20.120.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP and Internet

Administrative Status	Up
------------------------------	----

Configuring OSPF on the FortiGate devices

Three of the routers are designated routers (DR) and one is a backup DR (BDR). This is achieved through the lowest router ID numbers, or OSPF priority settings.

Also, each area needs to be configured as each respective type of area: stub, backbone, or regular. This affects how routes are advertised into the area.

To configure OSPF on Router1 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. Enter **10.11.101.1** for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	1.1.1.1
Type	Stub
Authentication	None

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.101.0/255.255.255.0
Area	1.1.1.1

5. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Accounting
Interface	port1 (internal)
IP	10.11.101.1
Authentication	None

6. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.1
Authentication	None

To configure OSPF on Router2 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. Enter 10.11.102.2 for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.102.2/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.110.2/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.111.2/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.102.2
Authentication	None

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.2
Authentication	None

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.2
Authentication	None

To configure OSPF on Router3 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. Enter 10.11.103.3 for the **Router ID** and select **Apply**.
3. In **Areas**, select **Create New**, set the following information, and select **OK**.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.102.3/255.255.255.0
Area	0.0.0.0

5. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.110.3/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.111.3/255.255.255.0
Area	0.0.0.0

7. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	RnD network
Interface	port1 (internal)
IP	10.11.103.3
Authentication	None

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.3
Authentication	None

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.3
Authentication	None

To configure OSPF on Router4 - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. Enter 10.11.104.4 for the **Router ID** and then select **Apply**.
3. In **Areas**, select **Create New**.
4. Set the following information and select **OK**.

Area	2.2.2.2
Type	Regular
Authentication	None

5. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.104.0/255.255.255.0
Area	0.0.0.0

6. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	10.11.111.0/255.255.255.0
Area	0.0.0.0

7. In **Networks**, select **Create New**, set the following information, and select **OK**.

IP/Netmask	172.20.120.0/255.255.255.0
Area	0.0.0.0

8. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Network Admin network
Interface	port1 (internal)
IP	10.11.104.4
Authentication	None

9. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	Backbone2
Interface	port2 (external2)
IP	10.11.111.4
Authentication	None

10. In **Interfaces**, select **Create New**, set the following information, and select **OK**.

Name	ISP
Interface	port3 (ISP)
IP	172.20.120.4
Authentication	None

Configuring other networking devices

All network devices on this network are running OSPF routing. The user networks (Accounting, R&D, and Network Administration) are part of one of the three areas.

The ISP needs to be notified of your network configuration for area 2.2.2.2. Your ISP won't advertise your areas externally as they're intended as internal areas. External areas have assigned unique numbers. The area numbers used in this example are similar to the 10.0.0.0 and 192.168.0.0 subnets used in internal networking.

Testing network configuration

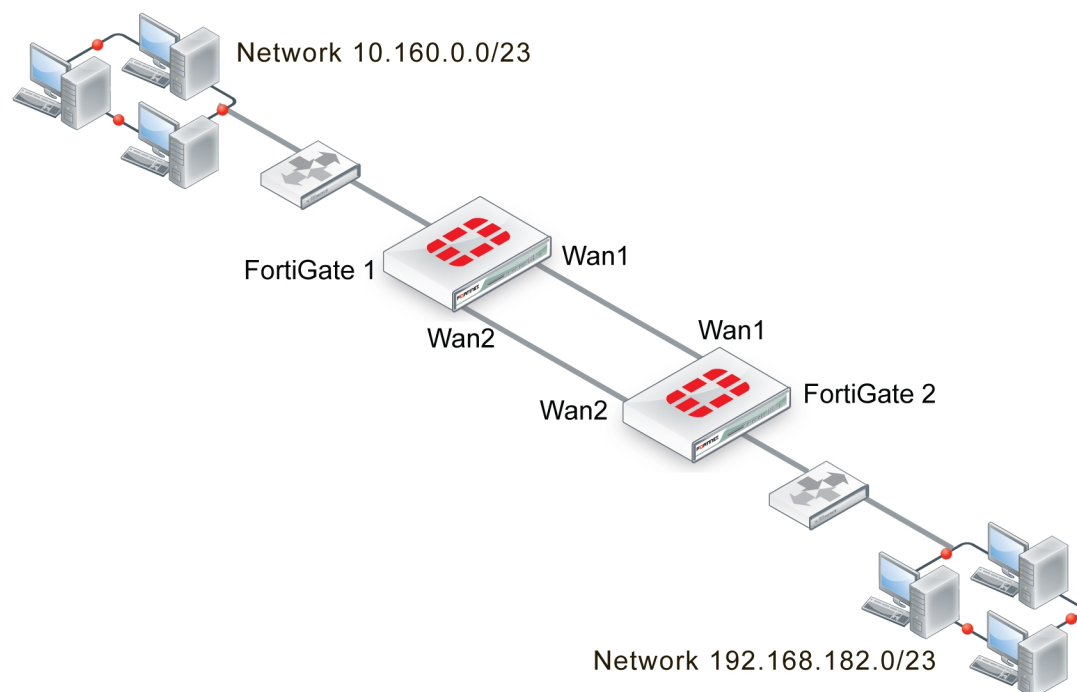

There are two main areas to test in this network configuration: network connectivity and OSPF routing.

To test network connectivity, see if computers on the Accounting or R&D networks can access the Internet. If you need troubleshooting network connectivity, see the *Troubleshooting Handbook*.

To test OSPF routing, check the routing tables on the FortiGate devices to ensure the expected OSPF routes are present. If you need help troubleshooting OSPF routing, see ["Troubleshooting OSPF" on page 2158](#).

Controlling redundant links by cost

In this scenario, two FortiGate devices have redundant links: one link between their WAN1 interfaces and one link between their WAN2 interfaces.

FortiGate 1 should learn the route to network 192.168.182.0 and FortiGate 2 should learn the route to network 10.160.0.0. Under normal conditions, they should learn these routes through the WAN1 link. The WAN2 link should be used only as a backup.

With the default settings, each FortiGate learns these routes from both WAN1 and WAN2.

FortiGate 1:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.2.2.2 1 Full/Backup 00:00:33 10.182.0.187 wan1
10.2.2.2 1 Full/Backup 00:00:31 10.183.0.187 wan2
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:01
[110/10] via 10.182.0.187, wan1, 00:00:01
O 192.168.182.0/23 [110/20] via 10.183.0.187, wan2, 00:02:04
[110/20] via 10.182.0.187, wan1, 00:02:04
```

FortiGate 2:

```
FGT2 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.1.1.1 1 Full/DR 00:00:38 10.182.0.57 wan1
10.1.1.1 1 Full/DR 00:00:38 10.183.0.57 wan2
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.183.0.57, wan2, 00:00:39
```

```
[110/20] via 10.182.0.57, wan1, 00:00:39
```

Adjusting the route costs

On both FortiGate devices, the cost of the route through WAN2 is adjusted higher so that this route will only be used if the route through WAN1 is unavailable. The default cost is 10. The WAN2 route will be changed to a cost of 200.

On both FortiGate devices:

```
config router ospf
  config ospf-interface
    edit "WAN2_higher_cost"
      set cost 200
      set interface "wan2"
    end
```

Now, both FortiGate devices use only the WAN1 route:

FortiGate 1:

```
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.182.0.187, wan1, 00:00:40
O 192.168.182.0/23 [110/20] via 10.182.0.187, wan1, 00:00:40
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.182.0.57, wan1, 00:09:37
```

LSDB check on FortiGate 1:

```
FGT1 # get router info ospf database router lsa
Router Link States (Area 0.0.0.0)
LS age: 81
Options: 0x2 (*|---|---|E|)

```

Verifying route redundancy

Bring down WAN1 and then check the routes on the two FortiGate devices.

FortiGate 1:

```
FGT1 # get router info routing-table ospf
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:06
O 192.168.182.0/23 [110/210] via 10.183.0.187, wan2, 00:00:06
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/210] via 10.183.0.57, wan2, 00:00:14
```

The WAN2 interface is now in use on both units.

BGP

BGP contains two distinct subsets: internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect many different networks together and is the main routing protocol for the Internet backbone. FortiGate devices support iBGP, and eBGP only for communities.

BGP was first used in 1989. The current version, BGP-4, was released in 1995 and is defined in [RFC 1771](#). That RFC has since been replaced by [RFC 4271](#). The main benefits of BGP-4 are classless inter-domain routing and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol. Other routing protocols use UDP.

BGP makes routing decisions based on path, network policies, and rulesets instead of the hop-count metric as RIP does, or cost-factor metrics as OSPF does.

BGP-4+ supports IPv6. It was introduced in [RFC 2858](#) and [RFC 2545](#).

BGP is the routing protocol used on the Internet. It was designed to replace the old Exterior Gateway Protocol (EGP) which had been around since 1982, and was very limited. BGP enabled more networks to take part in the Internet backbone to effectively decentralize it and make the Internet more robust, and less dependent on a single ISP or backbone network.

Parts and terminology of BGP

In a BGP network, there are some terms that need to be explained before going ahead. Some parts of BGP aren't explained here because they're common to other dynamic routing protocols. When determining your network topology, note that the number of available or supported routes isn't set by the configuration but depends on the available memory on the FortiGate. For more information about the parts of BGP that aren't listed here, see ["Dynamic routing" on page 2093](#).

BGP and IPv6

FortiGate devices support IPv6 over BGP using the same `config router bgp` CLI command as IPv4 but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the "6" on the end of the keyword, such as `config network6` or `set allowas-in6`. For more information about IPv6 BGP keywords, see the [FortiOS CLI Reference](#).

IPv6 BGP commands include:

```
config router bgp
  set activate6 {enable | disable}
  set allowas-in6 <max_num_AS_integer>
  set allowas-in-enable6 {enable | disable}
  set as-override6 {enable | disable}
  set attribute-unchanged6 [as-path] [med] [next-hop]
  set capability-default-originate6 {enable | disable}
  set capability-graceful-restart6 {enable | disable}
  set capability-origf6 {both | none | receive | send}
  set default-originate-route-map6 <routemap_str>
  set distribute-list-in6 <access-list-name_str>
  set distribute-list-out6 <access-list-name_str>
  set filter-list-in6 <aspath-list-name_str>
  set filter-list-out6 <aspath-list-name_str>
  set maximum-prefix6 <prefix_integer>
  set maximum-prefix-threshold6 <percentage_integer>
```

```

set maximum-prefix-warning-only6 {enable | disable}
set next-hop-self6 {enable | disable}
set prefix-list-in6 <prefix-list-name_str>
set prefix-list-out6 <prefix-list-name_str>
set remove-private-as6 {enable | disable}
set route-map-in6 <route-map-name_str>
set route-map-out6 <route-map-name_str>
set route-reflector-client6 {enable | disable}
set route-server-client6 {enable | disable}
set send-community6 {both | disable | extended | standard}
set soft-reconfiguration6 {enable | disable}
set unsuppress-map6 <route-map-name_str>
config network6
config redistribute6
end

```

Role of routers in BGP networks

Dynamic routing has a number of different roles that routers can fill, such as those covered in . BGP has a number of custom roles that routers can fill. These include speaker routers, peer routers or neighbors, and route reflectors.

Speaker routers

Any router that's configured for BGP is considered a BGP speaker. This means that a speaker router advertises BGP routes to its peers.

Any routers on the network that aren't speaker routers aren't treated as BGP routers.

Peer routers or neighbors

In a BGP network, all neighboring BGP routers or peer routers are routers that are connected to a FortiGate. A FortiGate learns about all other routers through these peers.

You need to manually configure BGP peers on a FortiGate as neighbors. Otherwise, these routers won't be seen as peers, but simply as other routers on the network that don't support BGP. Optionally, you can use MD5 authentication to password-protect BGP sessions with those neighbors (see [RFC 2385](#)).

You can configure up to 1000 BGP neighbors on a FortiGate. You can clear all or some BGP neighbor connections (sessions), using the `execute router clear bgp` CLI command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the following CLI command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the following CLI command:

```
execute router clear bgp as 650001
```

To remove route flap dampening information for the 10.10.0.0/16 subnet, enter the following CLI command:

```
execute router clear bgp dampening 10.10.0.0/16
```

In the following diagram, Router A is directly connected to five other routers in a network that contains 12 routers. These routers (the ones in the blue circle) are Router A's peers or neighbors.

Router A and its five peer routers

As a minimum, when configuring BGP neighbors, you must enter their IP address and the AS number (remote-as). This is all of the information the GUI allows you to enter for a neighbor.

The BGP commands related to neighbors are quite extensive and include:

```
config router bgp
config neighbor
  edit <neighbor_address_ipv4>
    set activate {enable | disable}
    set advertisement-interval <seconds_integer>
    set allowas-in <max_num_AS_integer>
    set allowas-in-enable {enable | disable}
    set as-override {enable | disable}
    set attribute-unchanged [as-path] [med] [next-hop]
    set bfd {enable | disable}
    set capability-default-originate {enable | disable}
    set capability-dynamic {enable | disable}
    set capability-graceful-restart {enable | disable}
    set capability-orf {both | none | receive | send}
    set capability-route-refresh {enable | disable}
    set connect-timer <seconds_integer>
    set description <text_str>
    set distribute-list-in <access-list-name_str>
    set distribute-list-out <access-list-name_str>
    set dont-capability-negotiate {enable | disable}
    set ebgp-enforce-multihop {enable | disable}
    set ebgp-multihop {enable | disable}
    set ebgp-multihop-ttl <seconds_integer>
    set filter-list-in <aspath-list-name_str>
    set filter-list-out <aspath-list-name_str>
    set holdtime-timer <seconds_integer>
    set interface <interface-name_str>
    set keep-alive-timer <seconds_integer>
    set maximum-prefix <prefix_integer>
    set maximum-prefix-threshold <percentage_integer>
    set maximum-prefix-warning-only {enable | disable}
    set next-hop-self {enable | disable}
    set passive {enable | disable}
    set password <string>
```

```
    set prefix-list-in <prefix-list-name_str>
    set prefix-list-out <prefix-list-name_str>
    set remote-as <id_integer>
    set remove-private-as {enable | disable}
    set retain-stale-time <seconds_integer>
    set route-map-in <routemap-name_str>
    set route-map-out <routemap-name_str>
    set route-reflector-client {enable | disable}
    set route-server-client {enable | disable}
    set send-community {both | disable | extended | standard}
    set shutdown {enable | disable}
    set soft-reconfiguration {enable | disable}
    set strict-capability-match {enable | disable}
    set unsuppress-map <route-map-name_str>
    set update-source <interface-name_str>
    set weight <weight_integer>
end
end
end
```

Route reflectors

Route reflectors (RR) in BGP concentrate route updates so other routers only need to talk to the RRs to get all of the updates. This results in smaller routing tables, fewer connections between routers, faster responses to network topology changes, and less administration bandwidth. BGP RRs are defined in [RFC 1966](#).

In a BGP RR configuration, the AS is divided into different clusters that each include client and reflector routers. The client routers supply the reflector routers with the client's route updates. The reflectors pass this information along to other RRs and border routers. Only the reflectors need to be configured, not the clients, because the clients find the closest reflector and communicate with it automatically. The reflectors communicate with each other as peers. A FortiGate can be configured as either reflectors or clients.

Since RRs are processing more than the client routers, the reflectors should have more resources to handle the extra workload.

Smaller networks running BGP typically do not require RRs. However, RRs are a useful feature for large companies, where their AS may include 100 routers or more. For example, a full mesh 20 router configuration within an AS, there would have to be 190 unique BGP sessions just for routing updates within the AS. The number of sessions jumps to 435 sessions for just 30 routers, or 4950 sessions for 100 routers. Based on these numbers, updating this many sessions will quickly consume the limited bandwidth and processing resources of the routers involved.

The following diagram illustrates how RRs can improve the situation when only six routers are involved. The AS without RRs requires 15 sessions between the routers. In the AS with RRs, the two RRs receive route updates from the reflector clients (unlabeled routers in the diagram) in their cluster, as well as other RRs, and pass them on to the border router. The RR configuration requires only six sessions. This example shows a reduction of 60% for the number of required sessions.

Required sessions within an AS with and without RRs

The BGP commands related to RRs include:

```
config router bgp
  config neighbor
    set route-reflector-client {enable | disable}
    set route-server-client {enable | disable}
  end
end
```

Confederations

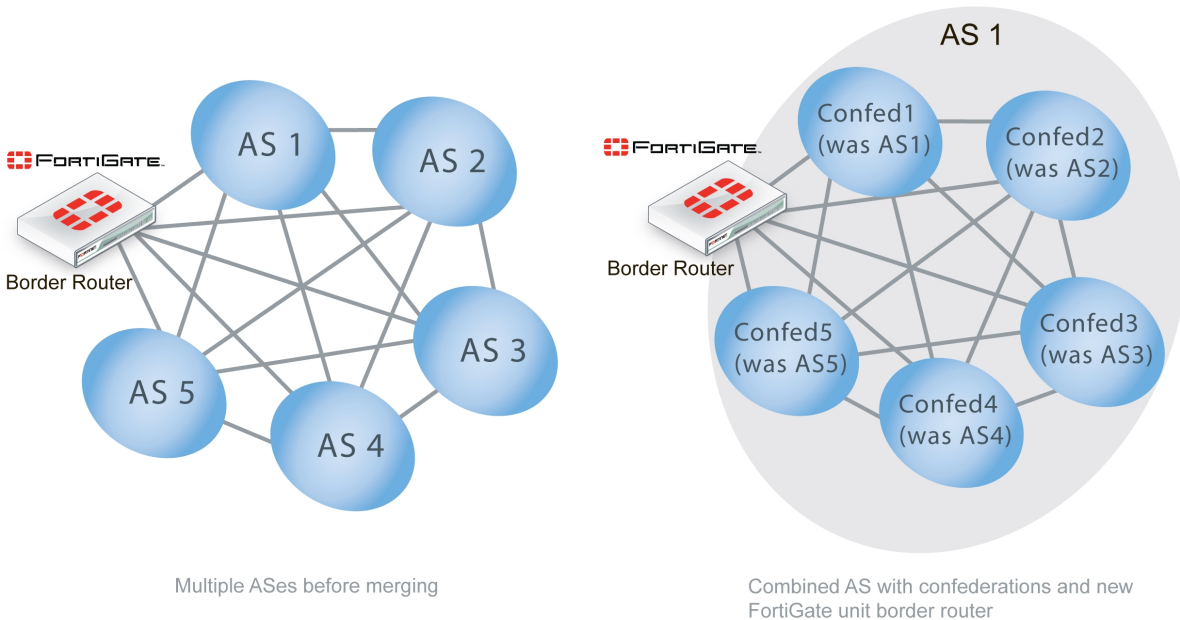

Confederations were introduced to reduce the number of BGP advertisements on a segment of the network and reduce the size of the routing tables. Confederations essentially break up an AS into smaller units.

Confederations are defined in [RFC 3065](#) and [RFC 1965](#).

Within a confederation, all routers communicate with each other in a full mesh arrangement. Communications between confederations is more like inter-AS communications because many of the attributes are changed as they would be for BGP communications leaving the AS, or eBGP.

Confederations are useful when merging ASs. Each AS being merged can easily become a confederation, which requires few changes. Any additional permanent changes can then be implemented over time, as required. The diagram below shows the group of ASs before merging and the corresponding confederations afterward, as part of the single AS with the addition of a new border router. It should be noted that after merging, if the border router becomes a route reflector, then each confederation only needs to communicate with one other router instead of five others.

AS merging using confederations

Confederations and RRs perform similar functions: they both sub-divide large ASs for more efficient operation. They differ in that route reflector clusters can include routers that aren't members of a cluster, whereas routers in a confederation must belong to that confederation. Also, confederations place their confederation numbers in the AS_PATH attribute, making it easier to trace.

It's important to note that while confederations essentially create sub-ASs, all the confederations within an AS appear as a single AS to external ASs.

Confederation related BGP commands include the following:

```
config router bgp
  set confederation-identifier <peerid_integer>
end
```

BGP conditional advertisements

Normally, routes are propagated regardless of the existence of a different path. The BGP conditional advertisement feature allows a route not to be advertised, based on the existence or non-existence of other routes. With this feature, a child table under `bgp.neighbor` is introduced. Any route matched by one of the route-maps specified in the table will be advertised to the peer, based on the corresponding route-map condition.

You can enable and disable conditional advertisements using the CLI.

To configure BGP conditional advertisements - CLI:

```
config router bgp
  set as 3
  config neighbor
    edit "10.10.10.10"
      set remote-as 3
      config conditional-advertise
        edit "route-map-to-match-sending"
```

```

        set condition-routemap "route-map-to-match-condition"
        set condition-type [exist | non-exist]
    next
end
next
end

```

BGP neighbor groups

The BGP neighbor group feature allows a large number of neighbors to be configured automatically based on a range of neighbors' source addresses.

To configure BGP neighbor groups - CLI:

Start by adding a BGP neighbor group:

```

config router bgp
  config neighbor-group
    edit <neighbor-group-name>
      set remote-as 100
    ...

```

(All options for BGP neighbor group are supported except `password`.)

```

end

```

Then add a BGP neighbor range:

```

config router bgp
  config neighbor-range
    edit 1
      set prefix 192.168.1.0/24
      set max-neighbor-num 100
      set neighbor-group <neighbor-group-name>
    next
  end

```

Network Layer Reachability Information

Network Layer Reachability Information (NLRI) is unique to BGP-4. It's sent as part of the update messages sent between BGP routers and contains information necessary to supernet, or aggregate route, information. The NLRI includes the length and prefix that, when combined, are the address of the aggregated routes referred to.

There is only one NLRI entry per BGP update message.

BGP attributes

Each route in a BGP network has a set of attributes associated with it. These attributes define the route and are modified, as required, along the route.

BGP can work well with mostly default settings, but if you're going to change settings you need to understand the roles of each attribute and how they affect those settings.

The BGP attributes include:

Attribute	Description
AS_PATH	A list of ASs a route has passed through. For more information, see "AS_PATH" on page 2194 .
MULTI_EXIT_DESC (MED)	Which router to use to exit an AS with more than one external connection. For more information, see "MULTI_EXIT_DESC" on page 2195 .
COMMUNITY	Used to apply attributes to a group of routes. For more information, see "COMMUNITY" on page 2195 .
NEXT_HOP	Where the IP packets should be forwarded to, like a gateway in static routing. For more information, see "NEXT_HOP" on page 2196 .
ATOMIC_AGGREGATE	Used when routes have been summarized to tell downstream routers not to de-aggregate the route. For more information, see "ATOMIC_AGGREGATE" on page 2196 .
ORIGIN	Used to determine if the route is from the local AS or not. For more information, see "ORIGIN" on page 2196 .
LOCAL_PREF	Used only within an AS to select the best route to a location (like MED).

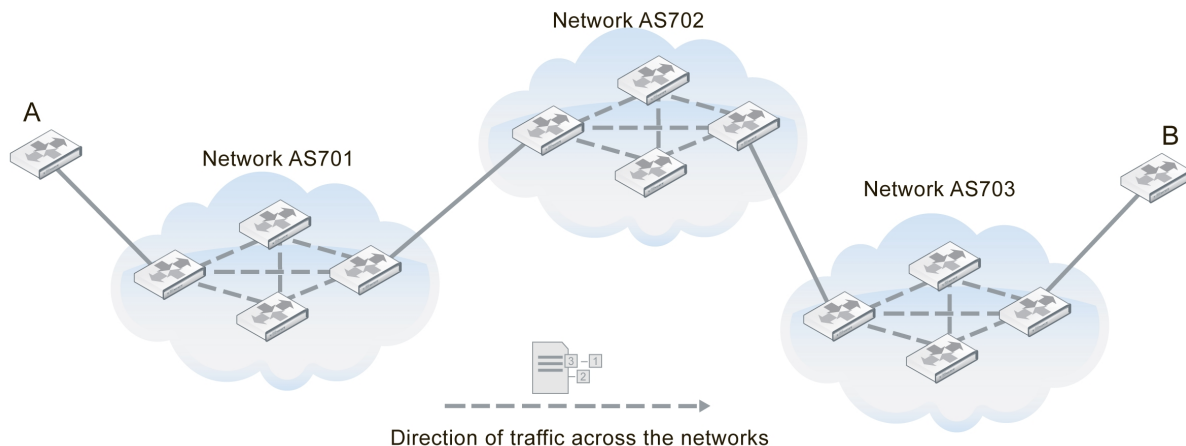

Inbound policies on FortiGate devices can change the NEXT-HOP, LOCAL-PREF, MED and AS-PATH attributes of an internal BGP (iBGP) route for its local route selection purposes. However, outbound policies on the device can't affect these attributes.

AS_PATH

AS_PATH is the BGP attribute that keeps track of each AS that a route advertisement has passed through. AS_PATH is used by confederations and by exterior BGP (EBGP) to help prevent routing loops. A router knows there is a loop if it receives an AS_PATH with that router's AS in it. The diagram below shows the route between Router A and Router B. The AS_PATH from A to B would read 701,702,703 for each AS that the route passes through.

As of the beginning of 2010, the industry upgraded from 2-byte to 4-byte AS_PATHs. This upgrade was due to the imminent exhaustion of 2-byte AS_PATH numbers. FortiOS supports 4-byte AS_PATHs in its BGP implementation.

AS_PATH of 701,702, 703 between routers A and B

The BGP commands related to AS_PATH include the following:

```
config router bgp
  set bestpath-as-path-ignore {enable | disable}
end
```

MULTI_EXIT_DESC

BGP AS systems can have one or more routers that connect them to other ASs. For ASs with more than one connecting router, the Multi-Exit Discriminator (MED) lists which router is best to use when leaving the AS. The MED is based on attributes, such as delay. It's a recommendation only, as some networks may have different priorities.

BGP updates advertise the best path to a destination network. When a FortiGate receives a BGP update, the FortiGate examines the MED attribute of potential routes to determine the best path to a destination network before recording the path in the local FortiGate routing table.

FortiGate devices have the option to treat any routes without an MED attribute as the worst possible routing choice. This can be useful because a lack of MED information is a lack of routing information, which can be suspicious as a possible hacking attempt or an attack on the network. At best, it signifies an unreliable route to select.

The BGP commands related to MED include the following:

```
config router bgp
  set always-compare-med {enable | disable}
  set bestpath-med-confed {enable | disable}
  set bestpath-med-missing-as-worst {enable | disable}
  set deterministic-med {enable | disable}
  config neighbor
    set attribute-unchanged [as-path] [med] [next-hop]
  end
end
```

COMMUNITY

A community is a group of routes that have the same routing policies applied to them. This saves time and resources. A community is defined by the COMMUNITY attribute of a BGP route.

A FortiGate can set the COMMUNITY attribute of a route to assign the route to predefined paths (see [RFC 1997](#)). The FortiGate can examine the COMMUNITY attribute of learned routes to perform local filtering and/or redistribution.

The BGP commands related to COMMUNITY include the following:

```
config router bgp
    set send-community {both | disable | extended | standard}
end
```

NEXT_HOP

The NEXT_HOP attribute says what IP address the packets should be forwarded to next. Each time the route is advertised, this value is updated. The NEXT_HOP attribute is much like a gateway in static routing.

FortiGate devices allow you to change the advertising of the FortiGate device's IP address (instead of the neighbor's IP address) in the NEXT_HOP information that is sent to IBGP peers. This is changed with the `config neighbor, set next-hop-self` command.

The BGP commands related to NEXT_HOP include the following:

```
config router bgp
    config neighbor
        set attribute-unchanged [as-path] [med] [next-hop]
        set next-hop-self {enable | disable}
    end
end
```

ATOMIC_AGGREGATE

The ATOMIC_AGGREGATE attribute is used when routes have been summarized. It indicates which AS and which router summarize the routes. It also tells downstream routers not to de-aggregate the route. Summarized routes are routes with similar information that have been combined, or aggregated, into one route that's easier to send in updates for. When it reaches its destination, the summarized routes are split back up into the individual routes.

The FortiGate doesn't specifically set this attribute in the BGP router command, but it's used in the route map command.

The CLI commands related to ATOMIC_AGGREGATE include the following:

```
config router route-map
    edit <route_map_name>
        config rule
            edit <route_map_rule_id>
                set set-aggregator-as <id_integer>
                set set-aggregator-ip <address_ipv4>
                set set-atomic-aggregate {enable | disable}
            end
        end
    end
```

ORIGIN

The ORIGIN attribute records where the route came from. The options can be IBGP, EBGP, or incomplete. This information is important because internal routes (IBGP) are, by default, higher priority than external routes (EBGP). However, incomplete ORIGINS are the lowest priority of the three.

The CLI commands related to ORIGIN include the following:

```
config router route-map
  edit <route_map_name>
    set comments <string>
    config rule
      edit <route_map_rule_id>
        set match-origin {egp | igp | incomplete | none}
      end
    end
  end
end
```

How BGP works

BGP is a link-state routing protocol and keeps link-state information about the status of each network link it has connected. A BGP router receives information from its peer routers that have been defined as neighbors. BGP routers listen for updates from these configured neighboring routers on TCP port 179.

A BGP router is a finite state machine with six various states for each connection. As two BGP routers discover each other and establish a connection, they go from the idle state and through the various states until they reach the established state. An error can cause the connection to drop and the state of the router to reset to either active or idle. These errors can be caused by TCP port 179 not being open, a random TCP port above port 1023 not being open, the peer address being incorrect, or the AS number being incorrect.

When BGP routers start a connection, they negotiate which (if any) optional features will be used, such as multiprotocol extensions, that can include IPv6 and VPNs.

IBGP versus EBGp

When you read about BGP, you often see EBGp or IBGP mentioned. These are both BGP routing, but BGP used in different roles. Exterior BGP (EBGP) involves packets crossing multiple autonomous systems (ASs) and interior BGP (IBGP) involves packets that stay within a single AS. For example, the AS_PATH attribute is only useful for EBGp where routes pass through multiple ASs.

These two modes are important because some features of BGP are used only for one of EBGp or IBGP. For example, confederations are used in EBGp and RRs are used only in IBGP. Also, routes learned from IBGP have priority over routes learned from EBGp.

FortiGate devices have some commands that are specific to EBGp, including the following:

- automatically resetting the session information to external peers if the connection goes down: `set fast-external-failover {enable | disable}`
- setting an administrative distance for all routes learned from external peers (you must also configure local and internal distances if this is set): `set distance-external <distance_integer>`
- enforcing EBGp multihops and their TTL (number of hops): `set ebgp-enforce-multihop {enable | disable}` and `set ebgp-multihop-ttl <seconds_integer>`

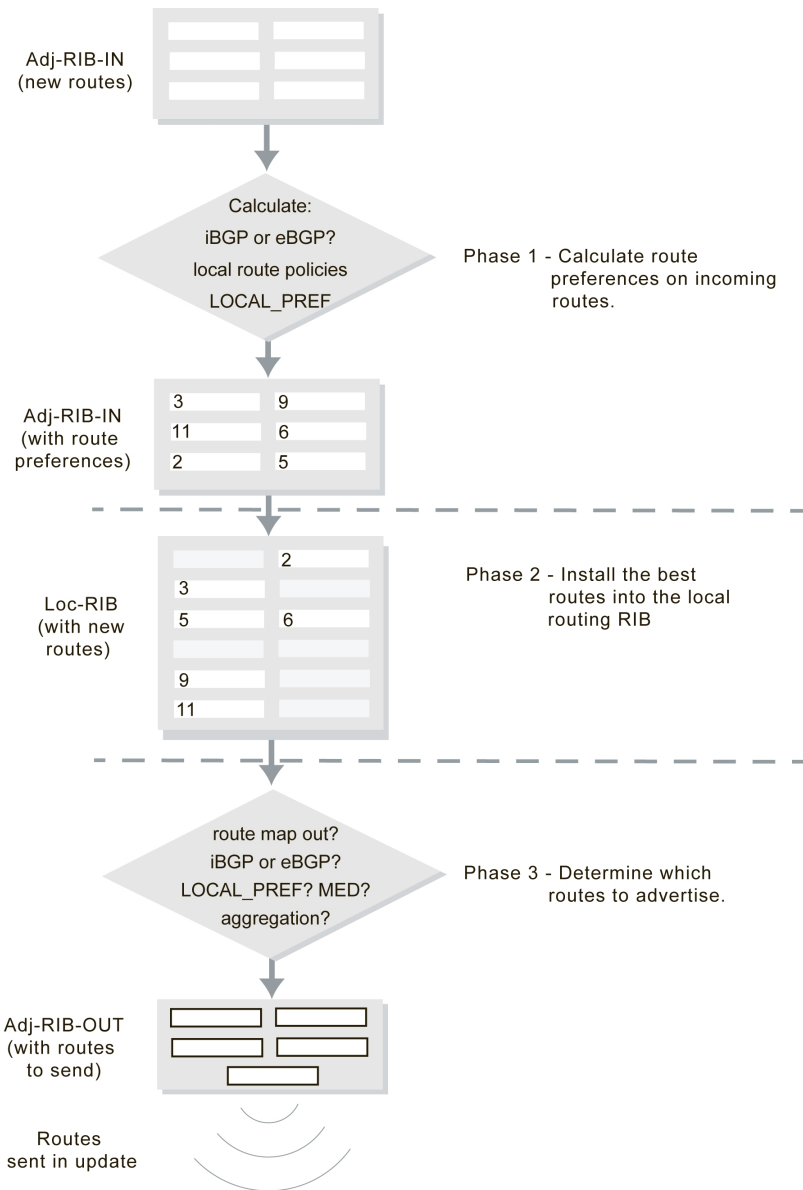

BGP path determination: which route to use

Firstly, recall that the number of available or supported routes isn't set by the configuration but depends on the available memory on the FortiGate. All learned routes and their attributes come into the BGP router in raw form. Before routes are installed in the routing table or are advertised to other routers, three levels of decisions must be made.

The three phases of BGP best path determination don't change. However, some manufacturers have added more information to the process, such as Cisco's WEIGHT attribute, to allow an administrator to force one route's selection over another.

There is one Adj-RIB-IN and Adj-RIB-OUT for each configured neighbor. They are updated when the FortiGate receives BGP updates or when the FortiGate sends out BGP updates.

The three phases of a BGP routing decision

Decision phase 1

At this phase, the decision is to calculate how preferred each route and its NRI are the Adjacent Routing Information Base Incoming (Adj-RIBs-In) compared to the other routes. For internal routes (IBGP), policy information or LOCAL_PREF is used. For external peer learned routes, it's based strictly on policy. These rules set up a list of which routes are most preferred going into Phase 2.

Decision phase 2

Phase 2 involves installing the best route to each destination into the local Routing Information Base (Loc-RIB). Effectively, the Loc-RIB is the master routing table. Each route from Phase 1 has their NEXT_HOP checked to ensure the destination is reachable. If it's reachable, the AS_PATH is checked for loops. After that, routes are installed based on the following decision process:

- If there's only one route to a location, it's installed.
- If there are multiple routes to the same location, use the most preferred route from Level 1.
- If there's a tie, break the tie based on the following, in descending order of importance: shortest AS_PATH, smallest ORIGIN number, smallest MED, EBGP over IBGP, smallest metric or cost for reaching the NEXT_HOP, BGP identifier, and lowest IP address.

Note that the new routes that are installed into the Loc-RIB are in addition to any existing routes in the table. Once Phase 2 is completed, the Loc-RIB will consist of the best of both the new and older routes.

Decision phase 3

Phase 3 is route distribution or dissemination. This is the process of deciding which routes the router will advertise. If there's any route aggregation or summarizing, it happens here. Also, any route filtering from route maps happens here.

Once Phase 3 is complete, an update can be sent out to update the neighbor of new routes.

Aggregate routes and addresses

BGP-4 allows classless routing, which uses netmasks as well as IP addresses. This classless routing allows the configuration of aggregate routes by stating the address bits the aggregated addresses have in common. For more information, see ["BGP" on page 1](#).

The ATOMIC_AGGREGATE attribute informs routers that the route has been aggregated and shouldn't be de-aggregated. An associated AGGREGATOR attribute include the information about the router that did the aggregating including its AS.

The BGP commands associated with aggregate routes and addresses are the following:

```
config router bgp
  config aggregate-address
    edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix <address_ipv4mask>
      set summary-only {enable | disable}
    end
  config aggregate-address6
    edit <aggr_addr_id>
      set as-set {enable | disable}
      set prefix6 <address_ipv6mask>
      set summary-only {enable | disable}
    end
```

Configuring BGP graceful restart process on timer

You can configure the BGP graceful restart process to stop only when the restart timer expires, using the following CLI commands:

```
config router bgp
```

```
set graceful-end-on-timer enable
```

Configuring option to bring down BGP neighbor when the link is down

You can configure an option to bring down BGP neighbors when the outgoing interface is down, using the following CLI commands:

```
config router bgp
config neighbor
edit <ip_address>
set linkdown-failover enable
```

Configuring option to keep routes for a period after the BGP neighbor is down

You can configure an option to keep routes for a period after the BGP neighbor is down. If you enable this option for a BGP neighbor, the route learned from the neighbor is kept for the configured `graceful-stalepath-time` after the neighbor is down because of hold timer expiration or TCP connection failure.

To configure this option, use the following CLI commands:

```
config router bgp
config neighbor
edit <ip_address>
set stale-route enable
```

BGP local-AS support

A FortiGate supports BGP local-AS. Local-AS allows you to configure a BGP speaker to have a real local-AS and a secondary local-AS for a specific neighbor, so its local-AS number appears different to different neighbors.

You can configure a BGP speaker to have a real local-AS and a secondary local-AS for a specific neighbor, so the local-AS number appears different to neighbor B and neighbor A.

To configure BGP local-AS for BGP peers - CLI:

```
config router bgp
config neighbor
edit "neighbor" / edit <ip_address>
...
set local-as 300 (?) / set local-as <integer>
set local-as-no-prepend {enable | disable}
set local-as-replace-as {enable | disable}
end
```

CLI option	Description
<ip_address>	The IP/IPv6 address of neighbor
<local-as <integer>>	The local-AS number
local-as-no-prepend { enable disable }	Set this to enable if you do not want to prepend local-AS to incoming updates.
local-as-replace-as { enable disable }	Set this to enable to replace a real AS with local-AS in outgoing updates.

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically, the problems with a BGP network that has been configured involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the following CLI command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the following CLI command:

```
execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term that is used if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables. This creates a lot of administration traffic on the network and the same traffic re-occurs when that router comes back online. If the problem is something like a faulty network cable that wobbles online and offline every 10 seconds, there could easily be an overwhelming amount of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate devices in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline, resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is unpleasant for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they don't expire during the failover process. Also, configuring graceful restart on the HA cluster helps with a smooth failover.

The first method of dealing with route flap is to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However, if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- [Hold down timer](#)
- [Dampening](#)
- [Graceful restart](#)
- [Troubleshooting BGP](#)

Hold down timer

The first line of defense to a flapping route is the hold down timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the hold down timer won't allow the FortiGate to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate. For the duration of the other outages, there won't be changes because the Fortigate is essentially treating this router as down. If the route is still flapping after the timer expires, it'll happen all over again.

Even if the route isn't flapping (for example, if it goes down, comes up, and stays back up) the timer still counts down and the route is ignored for the duration of the timer. In this situation, the route is seen as down longer than it really is but there will be only the one set of route updates. This isn't a problem in normal operation because updates aren't frequent.

Also, the potential for a route to be treated as down when it's really up can be viewed as a robustness feature. Typically, you don't want most of your traffic being routed over an unreliable route. So if there's route flap going on, it's best to avoid that route if you can. This is enforced by the hold down timer.

How to configure the hold down timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the hold down timer.

For example, your network has two routes that you want to set the hold down timer for. One is your main route (to 10.12.101.4) that all of your Internet traffic goes through, and it can't be down for long if it's down. The second is a low speed connection to a custom network that's used infrequently (to 10.13.101.4). The hold down timer for the main route should be fairly short, let's say 60 seconds instead of the default 180 seconds. The second route timer can be left at the default, or even longer since it's rarely used. In your BGP configuration this looks like the following:

```
config router bgp
  config neighbor
    edit 10.12.101.4
      set holddown-timer 60
    next
    edit 10.13.101.4
      set holddown-timer 180
    next
  end
end
```

Dampening

Dampening is a method that's used to limit the amount of network problems due to flapping routes. With dampening, the flapping still occurs but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second flap starts a timer where the router won't use that route because it's considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There's a period of time called the reachability half-life, after which a route flap will be suppressed for only half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate device's cache by using one of the `execute router clear bgp` CLI commands:

```
execute router clear bgp dampening {<ip_address> | <ip/netmask>}
or
execute router clear bgp flap-statistics {<ip> | <ip/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the following CLI command:

```
execute router clear bgp dampening 10.10.0.0/16
```

The BGP commands related to route dampening are the following:

```
config router bgp
  set dampening {enable | disable}
  set dampening-max-suppress-time <minutes_integer>
  set dampening-reachability-half-life <minutes_integer>
  set dampening-reuse <reuse_integer>
  set dampening-route-map <routemap-name_str>
  set dampening-suppress <limit_integer>
  set dampening-unreachability-half-life <minutes_integer>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded but the hardware can still function normally.

Graceful restart is best used for these situations where routing won't be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart doesn't have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster advertises that it's going offline, and won't appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table. If there's a flap, the HA cluster routing table will be out-of-date.

For example, the FortiGate is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting. When a router plans to go offline, it sends a message to its neighbours stating how long it expects to be offline. This way, its neighboring routers don't remove it from their routing tables. However, if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

Scheduled time offline

Graceful restart is a means for a router to advertise that it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time, if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that router will be offline for a long time.

FortiGate devices support both graceful restart of their own BGP routing software and neighboring BGP routers.

For example, if a neighbor of the FortiGate with an IP address of 172.20.120.120 supports graceful restart, enter the following CLI command:

```
config router bgp
  config neighbor
    edit 172.20.120.120
      set capability-graceful-restart enable
    end
  end
```

If you want to configure graceful restart on the FortiGate where you expect the Fortigate to be offline for no more than two minutes, and after three minutes the BGP network should consider the FortiGate to be offline, enter the following CLI commands:

```
config router bgp
  set graceful-restart enable
  set graceful-restart-time 120
  set graceful-stalepath-time 180
end
```

The BGP commands related to BGP graceful restart are the following:

```
config router bgp
  set graceful-restart { disable | enable }
  set graceful-restart-time <seconds_integer>
  set graceful-stalepath-time <seconds_integer>
  set graceful-update-delay <seconds_integer>
  config neighbor
    set capability-graceful-restart { enable | disable }
  end
end

execute router restart
```

Before the restart, the router sends its peers a message to say it's restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart, check its routes, and take care of them, if needed, after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it's done restarting.

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD communicate with each other and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated. For more information about BFD, see ["BFD" on page 2106](#).

Dual-homed BGP example

This is an example of a small network that uses BGP routing connections to two ISPs. This is a common configuration for companies that need redundant connections to the Internet for their business.

This configuration is for a small company connected to two ISPs. The company has one main office, the Head Office, and uses static routing for internal routing on that network.

Both ISPs use BGP routing and connect to the Internet directly. They want the company to connect to the ISP networks using BGP. They also use graceful restart to prevent updates that aren't needed and use smaller timer values to detect network failures faster.

As can be expected, the company wants to keep their BGP configuration relatively simple and easy to manage. The current configuration has only 3 routers to worry about: the 2 ISP border routers and the FortiGate. This means that the FortiGate has only two neighbor routers to configure.

This configuration has the added benefit of being easy to expand if the company wants to add a remote office in the future.

To keep the configuration simple, the company is allowing only HTTP, HTTPS, FTP, and DNS traffic out of the local network. This allows employees access to the Internet and their web mail.

Why dual home?

Dual homing means having two separate independent connections to the Internet. Servers in this configuration have also been called bastion hosts and can include DNS servers which require multiple connections.

Benefits of dual homing can include:

- Redundant Internet connection that essentially never fails
- Faster connections through one ISP or the other for some destinations, such as other clients of those ISPs
- Load balancing traffic to the company network
- Easier to enable more traffic through two connections than upgrading one connection to bigger bandwidth
- Easier to create protection policies for different traffic through a specific ISP

Some companies require reliable Internet access at all times as part of their business. Consider a doctor operating remotely who has their Internet connection fail — the consequences can easily be life or death.

Dual homing is an extra expense for the second ISP connection and more work to configure and maintain the more complex network topology.

Potential dual homing issues

BGP comes with load balancing issues and dual homing is in the same category. BGP doesn't inherently deal well with load balancing or getting default routes through BGP. Ideally, one connection may be best for certain destinations but it may not have that traffic routed to it, which makes the load balancing less than perfect. This kind of fine tuning can be very time consuming and usually results in a best effort situation.

When dual homing isn't configured properly, your network may become a link between your ISPs and result in very high traffic between the ISPs that doesn't originate from your network. The problem with this situation is that your traffic may not have the bandwidth it needs, and you'll also be paying for a large volume of traffic that isn't yours. This problem can be solved by not broadcasting or redistributing BGP routes between the ISPs.

If you learn your default routes from the ISPs, in this example, you may run into an asymmetric routing problem where your traffic loops out one ISP and back to you through the other ISP. If you think this may be happening, you can turn on asymmetric routing on the FortiGate (`config system settings, set asymmetric enable`) to verify if that's the problem. Turn this feature off once this is established, since it disables many features on the FortiGate by disabling stateful inspection. Solutions to this problem can include using static routes for default routes instead of learning them through BGP or configuring VDOMs on the FortiGate to provide a slightly different path back that isn't a true loop.

Network layout and assumptions

The network layout for the basic BGP example involves the company network being connected to both ISPs as shown below. In this configuration, the FortiGate is the BGP border router between the Company AS, ISP1's AS, and ISP2's AS.

The components of the layout include the following:

- The Company AS (AS number 1) is connected to ISP1 and ISP2 through the FortiGate.
- The Company has one internal network: the Head Office network at 10.11.101.0/24.
- The FortiGate internal interface is on the company's internal network with an IP address of 10.11.101.110.
- The FortiGate external1 interface is connected to ISP1's network with an IP address of 172.20.111.5, which is an address supplied by the ISP.
- The FortiGate external2 interface is connected to IPS2's network with an IP address of 172.20.222.5, which is an address supplied by the ISP.
- ISP1 AS has an AS number of 650001 and ISP2 has an AS number of 650002.
- Both ISPs are connected to the Internet.
- The ISP1 border router is a neighbor (peer) of the FortiGate. It has an address of 172.21.111.4.
- The ISP2 border router is a neighbor (peer) of the FortiGate. It has an address of 172.22.222.4.
- Apart from graceful restart and shorter timers (holdtimer and keepalive), default settings are to be used whenever possible.

Basic BGP network topology

Assumptions

The basic BGP configuration procedure follows these assumptions:

- ISP1 is the preferred route and ISP2 is the secondary route
- All basic configuration can be completed in both the GUI and CLI
- Only one AS is used for the company

For these reasons, this example configuration does not include:

- Bidirectional forwarding detection
- Route maps
- Access lists
- Changing redistribution defaults (make link when example is set up)
- IPv6

For more information about these features, see the corresponding section.

Configuring the FortiGate

In this topology, the FortiGate is the link between the company network and the ISP network. The FortiGate is the only BGP router on the company network, but there's at least one other BGP router on the ISP network. There may be more BGP routers, but we don't have that information.

As mentioned in the general configuration steps, the ISP must be notified of the company's BGP router configuration when complete as it will need to add the FortiGate BGP router as a neighbor router on its domain. This step is required for the FortiGate to receive BGP routing updates from the ISP network and outside networks.

If the ISP has any special BGP features enabled, such as graceful restart or route dampening, that should be determined ahead of time so those features can be enabled on the FortiGate.

To configure the FortiGate as a BGP router:

1. [Configure interfaces and default routes](#)
2. [Configure firewall services, addresses, and policies](#)
3. [Set the FortiGate BGP information](#)
4. [Add the internal network to the AS](#)
5. [Additional FortiGate BGP configuration](#)

Configure interfaces and default routes

The FortiGate is connected to three networks: the company network on the internal interface, the ISP1 network on the external1 interface, and the ISP2 network on the external2 interface.

This example uses basic interface settings. Check with your ISP to determine if additional settings are required, such as setting the maximum MTU size or if gateway detection is supported.

High end FortiGate models don't have interfaces labeled as Internal or External. Instead, for clarity, we're using the alias feature to name interfaces for these roles.

Default routes to both external interfaces are configured here also. Both are needed in case one goes offline. ISP1 is the primary connection and has a smaller administrative distance so it will be preferred over ISP2. Both distances are set low so they will be preferred over any learned routes.

To configure the FortiGate interfaces - GUI:

1. Go to **Network > Interfaces**.
2. Edit port 1 (internal) interface.
3. Set the following information and select **OK**.

Alias	internal
IP/Network Mask	10.11.101.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	Company internal network
Interface State	Enabled

4. Edit port 2 (external1) interface.
5. Set the following information and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	ISP1 External BGP network
Interface State	Enabled

6. Edit port 3 (external2) interface.
7. Set the following information and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Comments	ISP2 External BGP network
Interface State	Enabled

To configure the FortiGate interfaces - CLI:

```
config system interface
  edit port1
    set alias internal
```

```

        set ip 10.11.101.110 255.255.255.0
        set allowaccess http https ssh
        set description "Company internal network"
        set status up
    next
    edit port2
        set alias external1
        set ip 172.21.111.5 255.255.255.0
        set allowaccess https ssh
        set description "ISP1 External BGP network"
        set status up
    next
    edit port3
        set alias external2
        set ip 172.22.222.5 255.255.255.0
        set allowaccess https ssh
        set description "ISP2 External BGP network"
        set status up
    next
end

```

To configure default routes for both ISPs - GUI:

1. Go to **Network > Static Routes**.
2. Delete any existing routes with a IP/Mask of address of 0.0.0.0/0.0.0.0
3. Select **Create New** and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.21.111.5
Interface	port2
Administrative Distance	10

4. Select **OK**.
5. Select **Create New** and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.22.222.5
Interface	port3
Administrative Distance	15

6. Select **OK**.

To configure default routes for both ISPs - CLI:

```

config router static
edit 1
    set device "port2"
    set distance 10

```

```
        set gateway 172.21.111.5
    next
    edit 2
        set device "port3"
        set distance 15
        set gateway 172.22.222.5
    next
end
```

Configure firewall services, addresses, and policies

To create the security policies, you create the firewall services group that will include all the services that will be allowed, define the addresses that will be used in the security policies, and configure the security policies themselves.

To keep the configuration simple, the company is allowing only HTTP traffic out of the local network. This will allow employees access to the Internet and their web mail. DNS services will also be allowed through the firewall.

The security policies will allow HTTP traffic (port 80 and port 8080), HTTPS traffic (port 443), FTP traffic (port 21), and DNS traffic (port 53 and port 953) in both directions. Also, BGP (port 179) may need access through the firewall.

For added security, you may want to define a smaller range of addresses for the internal network. For example, if only 20 addresses are used, only allow those addresses in the range.

To keep things simple, a zone is used to group the two ISP interfaces together. This allows for the use of one security policy to apply to both ISPs at the same time. Remember to block intra-zone traffic as this helps to prevent one ISP sending traffic to the other ISP through the FortiGate, using your bandwidth. The zone keeps configuration simple and if there's a need for separate policies for each ISP in the future, they can be created and the zone can be deleted.

The addresses that will be used are the addresses of the FortiGate internal and external ports and the internal network.

More policies or services can be added in the future as applications are added to the network. For more information about security policies, see the [FortiOS Firewall Handbook](#).

When configuring security policies, always enable logging to help you track and debug your traffic flow.

To create a firewall services group - GUI:

1. Go to **Policy & Objects > Services**, select the dropdown arrow next to **Create New** and select **Service Group**.
2. For **Group Name**, enter "Basic_Services".
3. From the **Members** dropdown, choose the following six services: BGP, FTP, FTP_GET, FTP_PUT, DNS, HTTP, and HTTPS.
4. Select **OK**.

To create a firewall services group - CLI:

```
config firewall service group
```

```

edit "Basic_Services"
    set member "BGP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS"
next
end

```

To create a zone for the ISP interfaces - GUI:

1. Go to **Network > Interfaces**.
2. Select the caret to the right of **Create New** and then select **Zone**.
3. Enter the following information:

Name	ISPs
Block intra-zone traffic	enable
Interface Members	port2 port3

4. Select **OK**.

To create a zone for the ISP interfaces - CLI:

```

config system zone
    edit "ISPs"
        set interface "port2" "port3"
        set intrazone block
    next
end

```

To add the firewall addresses - GUI:

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New** and set the following information:

Category	Address
Name	Internal_network
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	port1

3. Select **OK**.

To add the firewall addresses - CLI:

```

config firewall address
    edit Internal_network
        set associated-interface port1
        set subnet 10.11.101.0 255.255.255.0
    next
end

```

To add the HTTP and DNS security policies - GUI:

1. Go to **Policy & Objects > IPv4 Policy**, and select **Create New**.
2. Set the following information:

Incoming Interface	port1(internal)
Outgoing Interface	ISPs
Source	Internal_network
Destination	All
Schedule	Always
Service	Basic_services
Action	ACCEPT
Firewall / Network Options	Enable NAT
Log Allowed Traffic	Enable
Comments	ISP1 basic services out policy

3. Select **OK**.
4. Select **Create New** and set the following information:

Incoming Interface	ISPs
Outgoing Interface	port1(internal)
Source	All
Destination	Internal_network
Schedule	Always
Service	Basic_services
Action	ACCEPT
Firewall / Network Options	Enable NAT
Log Allowed Traffic	Enable
Comments	ISP1 basic services in policy

To add the security policies - CLI:

```
config firewall policy
edit 1
```

```

        set srcintf "port1"
        set srcaddr "Internal_network"
        set dstintf "ISPs"
        set dstaddr "all"
        set schedule "always"
        set service "Basic_services"
        set action accept
        set nat enable
        set profile-status enable
        set logtraffic enable
        set comments "ISP1 basic services out policy"
    next
edit 2
    set srcintf "ISPs"
    set srcaddr "all"
    set dstintf "port1"
    set dstaddr "Internal_network"
    set schedule "always"
    set service "Basic_services"
    set action accept
    set nat enable
    set profile-status enable
    set logtraffic enable
    set comments "ISP1 basic services in policy"
next
end

```

Set the FortiGate BGP information

When using the default information, there are only two fields to set to configure the FortiGate as a BGP router.

For this configuration, the FortiGate will be in a stub area with one route out — the ISP BGP router. Until you configure the ISP router as a neighbor, even that route out isn't available. So, while after this part of the configuration is complete, the FortiGate will be running BGP, it won't know about any other routers running BGP until the next part of the configuration is complete.

To set the BGP router information - GUI:

1. Go to **Network > BGP**.
2. Set the following information and select **OK**.

Local AS	1
Router ID	10.11.101.110

To set the BGP router information - CLI:

```

config router BGP
    set as 1
    set router-id 10.11.101.110
end

```

Add the internal network to the AS

The company is one AS with the FortiGate configured as the BGP border router connecting that AS to the two ISPs ASs. The internal network in the Company's AS must be defined. If there were other networks in the company, such as regional offices, they would be added here as well.

To set the networks in the AS - GUI:

1. Go to **Network > BGP**.
2. Under **Networks**, set the **IP/Netmask** to 10.11.101.0/255.255.255.0 and select **Add**.

To set the networks in the AS - CLI:

```
config router bgp
  config network
  edit 1
    set prefix 10.11.101.0 255.255.255.0
  next
end
end
```

Add BGP neighbor information

The configuration won't work unless you set **Remote AS** neighbors. This can be done in either the GUI or the CLI.

To configure the BGP neighbors - GUI:

1. Go to **Network > BGP**.
2. Add a **Neighbors IP** of 172.21.111.4 with the **Remote AS** set to 650001, then click **Add/Edit**.
3. Add another **Neighbors IP** of 172.22.222.4 with the **Remote AS** set to 650002, then click **Add/Edit**.

To configure the BGP neighbors - CLI:

```
config router BGP
  set as 1
  config neighbor
  edit "172.21.111.4"
    set remote-as 650001
  next
  edit "172.22.222.4"
    set remote-as 650002
  next
end
end
```

Additional FortiGate BGP configuration

At this point, those are all the settings that can be done in both the GUI and the CLI. The remaining configuration must be completed in the CLI.

These additional settings are mainly determined by your ISP requirements. They will determine your timers, such as keepalive timers, if extended features like BFD and graceful restart are being used, and so on. For this

example, some common simple features are being used to promote faster detections of network failures, which will result in better service for the company's internal network users.

The ISPs don't require authentication between peer routers.

These commands will enable or modify the following features on the FortiGate and, where possible, on neighboring routers as well:

- `bestpath-med-missing-as-worst`: Treats a route without an MED as the worst possible available route due to expected unreliability
- `fast-external-failover`: Immediately reset the session information associated with BGP external peers if the link used to reach them goes down
- `graceful-restart*`: Advertise reboots to neighbors so they don't see the router as offline, wait before declaring them offline, and how long to wait when they reboot before advertising updates. These commands apply to neighbors and are part of the BGP capabilities. This prevents unneeded routing updates.
- `holdtime-timer`: How long the router will wait for a keepalive message before declaring a router offline. A shorter time will find an offline router faster.
- `keepalive-timer`: How often the router sends out keepalive messages to neighbor routers to maintain those sessions.
- `log-neighbor-changes`: Log changes to the status of neighbor routers. This can be useful for troubleshooting from both internal and external networks.
- `connect-timer`: How long (in seconds) the FortiGate will try to reach this neighbor before declaring it offline.
- `weight`: Used to prefer routes from one neighbor over the other. In this example, ISP1 is the primary connection so it's weighted higher than ISP2.

To configure additional BGP options - CLI:

```
config router bgp
  set bestpath-med-missing-as-worst enable
  set fast-external-failover enable
  set graceful-restart enable
  set graceful-restart-time 120
  set graceful-stalepath-time 180
  set graceful-update-delay 180
  set holdtime-timer 120
  set keepalive-timer 45
  set log-neighbor-changes enable
config neighbor
  edit 172.21.111.4
    set connect-timer 60
    set description "ISP1"
    set holdtime-timer 120
    set keepalive-timer 45
    set weight 250
  next
  edit 172.22.222.4
    set connect-timer 60
    set description "ISP2"
    set holdtime-timer 120
    set keepalive-timer 45
    set weight 100
  next
end
end
```

Configuring other networking devices

There are two other networking devices that need to be configured: the BGP routers for both ISPs.

The ISPs' routers must add the FortiGate as a neighbor so route updates can be sent in both directions. Note that ISP1 isn't directly connected to ISP2, that we're aware of.

Inform both of your ISPs of the FortiGate device's BGP information. Once they have configured their router, you can test your BGP connection to the Internet.

They will require your FortiGate device's IP address of the connected interface, the route ID, and your company's AS number.

Testing this configuration

With the dual-homed BGP configuration in place, you should be able to send and receive traffic, send and receive routes, and not have any routing loops. Testing the networks will confirm that things are working as expected.

In general, for routing, you need to look at the routing table on different routers to see what routes are being installed. You also need to sniff packets to see how traffic is being routed in real-time. These two sources of information will normally tell you what you need to know.

Testing of this example's network configuration should be completed in the following parts:

- [Testing network connectivity](#)
- [Verifying the FortiGate device's routing tables](#)
- [Verifying traffic routing](#)
- [Verifying the dual-homed side of the configuration](#)

Testing network connectivity

A common first step in testing a new network topology is to test to see if you can reach the Internet and other locations as expected. If not, you may be prevented by cabling issues, software, or other issues.

The easiest way to test connections is to use ping, once you ensure that all of the FortiGate interfaces and ISP routers have ping support enabled. Also, ensure that the security policies allow ping through the firewall.

Connections to test, in this example, are the internal network to ISP1's router or the Internet, and the same for ISP2. If you can connect on the external side of the Fortinet, try to ping the internal network. These three tests should prove your basic network connections are working.

Once you've finished testing the network connectivity, turn off ping support on the external interfaces for additional security.

Verifying the FortiGate device's routing tables

The FortiGate routing table contains the routes that are stored for future use. If you're expecting certain routes to be there and they're not, this is a good indicator that your configuration isn't what you expected.

The `get router info routing-table details` CLI command will provide you with the routing protocol, destination address, gateway address, interface, and weighting for every route, as well as if the address is directly connected or not.

If you want to limit the display to BGP routes only, use the `get router info routing-table bgp` CLI command. If there are no BGP routes in the routing table, nothing will be displayed. In the CLI command, you can replace BGP with static, or other routing protocols, to only display those routes.

If you want to see the contents of the routing information database (RIB), use the `get router info routing-table database` CLI command. This will display the incoming routes that may or may not make it into the routing table.

Verifying traffic routing

Traffic may be reaching the internal network, but it may be using a different route than you think to get there.

Use a browser to try to access the Internet.

If needed, allow traceroute and other diag ports to be opened until things are working properly. Then remove access for them again.

Look for slow hops on the traceroute, or pings to a location, as they may indicate network loops that need to be fixed.

Any locations that have an unresolved traceroute or ping must be examined and fixed.

Use network packet sniffing to ensure traffic is being routed as you expect.

Verifying the dual-homed side of the configuration

Since there are two connections to the Internet in this example, theoretically you can pull the plug on one of the ISP connections, and all traffic will go through the other connection. Alternately, you may choose to remove a default route to one ISP, remove that ISP's neighbor settings, or change the weightings to prefer the other ISP. These alternate ways to test dual-homing don't change physical cabling, which may be preferred in some situations.

If this doesn't work as expected, things to check include:

- Default static routes: If these are wrong or don't exist, the traffic can't get out.
- BGP neighbor information: If the ISP router information is incorrect, the FortiGate won't be able to talk to it.

Redistributing and blocking routes in BGP

During normal BGP operation, peer routers redistribute routes from each other. However, in some specific situations it may be best not to advertise routes from one peer, such as if the peer is redundant with another peer (they share the same routes exactly), if it might be unreliable in some way or for some other reason. The FortiGate can also take routes it learns from other protocols and advertise them in BGP, for example OSPF or RIP. If your company hosts its own web or email servers, external locations will require routes to your networks to reach those services.

In this example, the company has an internal network in an OSPF area and is connected to a BGP AS and two BGP peers. The company goes through these two peers to reach the Internet. However, Peer 1 routes won't be advertised to Peer 2. The company internal user and server networks are running OSPF, and will redistribute those routes to BGP so external locations can reach the web and email servers.

Network layout and assumptions

The network layout for the BGP redistributing routes example involves the company network being connected to two BGP peers, as shown below. In this configuration, the FortiGate is the BGP border router between the

Company AS and the peer routers.

The components of the layout include:

- There's only one BGP AS in this example shared by the FortiGate and both peers: AS 65001.
- The company's FortiGate device connects to the Internet through two BGP peers.
- The company's internal networks on the dmz interface of the FortiGate with an IP of 10.11.201.0/24.
- The FortiGate device's interfaces are connected as follows:
 - port1 (dmz) has IP 10.11.201.110 and is the internal user and server network
 - port2 (external1) has IP 172.21.111.4 and is connected to Peer 1's network
 - port3 (external2) has IP 172.22.222.4 and is connected to Peer 2's network
- Peer 1 has IP 172.21.111.5, and Peer 2 has IP 172.22.222.5.
- OSPF Area 1 is configured on the dmz interface of the FortiGate, and is the routing protocol used by the internal users and servers.

BGP network topology

Assumptions

The BGP redistributing routes configuration procedure follows these assumptions:

- The FortiGate has been configured following the Install Guide
- Interfaces port1, port2, and port3 exist on the FortiGate
- We do not know the router manufacturers of Peer 1 and Peer 2
- We do not know what other devices are on the BGP AS or OSPF Area
- All basic configuration can be completed in both GUI and CLI

- Access lists and route maps will only be configured in CLI
- VDOMs are not enabled on the FortiGate

Configuring the FortiGate

1. [Configuring networks and firewalls on the FortiGate](#)
2. [Configuring BGP on the FortiGate](#)
3. [Configuring OSPF on the FortiGate](#)
4. [Configuring other networking devices](#)
5. [Configuring ECMP support for BGP](#)

Configuring networks and firewalls on the FortiGate

The FortiGate has three interfaces connected to networks: two external and one dmz.

Security policies must be in place to allow traffic to flow between these networks.

Firewall services will change depending on which routing protocol is being used on that network: either BGP or OSPF. Beyond that, all services that are allowed will be allowed in both directions due to the internal servers. The services allowed are web server services (DNS, HTTP, HTTPS, SSH, NTP, FTP*, SYSLOG, and MYSQL), email services (POP3, IMAP, and SMTP), and general troubleshooting services (PING, TRACEROUTE). To increase security, PING and TRACEROUTE can be removed once the network is up and working properly. Other services can be added later, as needed.

To configure the interfaces - GUI:

1. Go to **Network > Interfaces**.
2. Edit port1 (dmz) interface.
3. Set the following information and select **OK**.

Alias	dmz
IP/Network Mask	10.11.201.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	OSPF internal networks
Administrative Status	Up

4. Edit port2 (external1) interface.
5. Set the following information and select **OK**.

Alias	external1
IP/Network Mask	172.21.111.4/255.255.255.0
Administrative Access	HTTPS SSH

Description	BGP external Peer 1
Administrative Status	Up

6. Edit port3 (external2) interface.
7. Set the following information and select **OK**.

Alias	external2
IP/Network Mask	172.22.222.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external2 Peer2
Administrative Status	Up

To configure the FortiGate interfaces - CLI:

```
config system interface
  edit port1
    set alias dmz
    set ip 10.11.201.110 255.255.255.0
    set allowaccess https ssh ping
    set description "OSPF internal networks"
    set status up
  next
  edit port2
    set alias external1
    set ip 172.21.111.5 255.255.255.0
    set allowaccess https ssh
    set description "external1 Peer 1"
    set status up
  next
  edit port3
    set alias external2
    set ip 172.22.222.5 255.255.255.0
    set allowaccess https ssh
    set description "external2 Peer 2"
    set status up
  next
end
```

To configure the firewall addresses - GUI:

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New** and set the following information.

Category	Address
Name	BGP_services

Type	Subnet / IP Range
Subnet / IP Range	10.11.201.0 255.255.255.0
Interface	port1

3. Select **OK**.

To configure the firewall addresses - CLI:

```
config firewall address
  edit "BGP_services"
    set associated-interface "port1"
    set subnet 10.11.201.0 255.255.255.0
  next
end
```

To configure firewall service groups - GUI:

1. Go to **Policy & Objects > Objects > Services**. Under the **Create New** dropdown menu, select **Service Group**.
2. Name the group BGP_Services.
3. Add the following services to the **Members** list: BGP, DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
4. Select **OK**.
5. Create another new **Service Group**.
6. Name the group OSPF_Services.
7. Add the following services to the *Members* list: DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, OSPF, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
8. Select **OK**.

To configure firewall service groups - CLI:

```
config firewall service group
  edit "BGP_services"
    set member "BGP", "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP"
      "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG"
  next
  edit "OSPF_services"
    set member "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS" "IMAP" "MYSQL"
      "NTP" "PING" "POP3" "SMTP" "SSH" "TRACEROUTE" "SYSLOG" "OSPF"
  next
end
```

Configuring BGP on the FortiGate

The only change from the standard BGP configuration for this example is configuring the blocking Peer 1's routes from being advertised to Peer 2. From the network topology you can guess that both of these peers likely share many routes in common and it doesn't make sense to advertise unneeded routes.

Blocking Peer 1's routes to Peer 2 is done with the `distribute-list-out` keyword. They allow you to select which routes you will advertise to a neighbor using an access list. In this case, we'll block all incoming routes from Peer 1 when we send updates to Peer 2. Otherwise Peer 1 and Peer 2 are regular neighbors.

The FortiGate redistributes routes learned from OSPF into BGP.

This is advanced configuration and the commands are only available in the CLI.

To create access list to block Peer 1 - CLI:

```
config access-list
  edit "block_peer1"
    config rule
      edit 1
        set prefix 172.21.111.0 255.255.255.0
        set action deny
        set exact-match enable
      end
    end
  end
```

To configure BGP on the FortiGate unit - CLI:

```
config router bgp
  set as 65001
  set router-id 10.11.201.110
  config redistribute ospf
    set status enable
  end
  config neighbor
    edit 172.22.222.5
      set remote-as 65001
      set distribute-list-out "block_peer1"
    next
    edit 172.21.111.5
      set remote-as 65001
    end
  end
end
```

Configuring OSPF on the FortiGate

This configuration involves only one OSPF area, so all traffic will be intra-area. If there were two or more areas with traffic going between them, it would be inter-area traffic. These two types are comparable to BGP's traffic within one AS (iBGP) or between multiple ASes (eBGP). Redistributing routes from OSPF to BGP is considered external because either the start or end point is a different routing protocol.

The OSPF configuration is basic, apart from redistributing BGP routes learned.

To configure OSPF on the FortiGate unit - GUI:

1. Go to **Router > Dynamic > OSPF**.
2. For Router ID enter `10.11.201.110` and then select **Apply**.
3. Under **Advanced Options > Redistribute**, select **BGP** and set the BGP **Metric** to 1.
4. For **Areas**, select **Create New**, enter the following information and then select **OK**.

Area (IP)	0.0.0.0
Type	Regular
Authentication	None

5. For **Networks**, select **Create New**.
6. Enter 10.11.201.0/255.255.255.0 for **IP/Netmask**, and select **OK**.
7. For **Interfaces**, select **Create New**.
8. Enter `OSPF_dmz_network` for **Name**.
9. Select `port1 (dmz)` for **Interface** and then select **OK**.

To configure OSPF on the FortiGate - CLI:

```
config router ospf
  set router-id 10.11.201.110
  config area
    edit 0.0.0.0
      set type regular
      set authentication none
    end
  config network
    edit 1
      set area 0.0.0.0
      set prefix 10.11.201.0 255.255.255.0
    end
  config interface
    edit "OSPF_dmz_network"
      set interface port1(dmz)
      set status enable
    end
  config redistribute bgp
    set status enable
    set metric 1
  end
end
```

Configuring other networking devices

As with all BGP configurations, the peer routers will need to be updated with the FortiGate device's BGP information, including IP address, AS number, and what capabilities are being used, such as IPv6, graceful restart, BFD, and so on.

Configuring ECMP support for BGP

Equal Cost Multiple Path (ECMP) is a mechanism that allows multiple routes to the same destination with different next-hops and load-balances routed traffic over those multiple next-hops.

- ECMP only works for routes that are sourced by the same routing protocol (Static Routes, OSPF, and BGP).
- ECMP is enabled, by default, with 10 paths.
- ECMP with static routes is effective if the routes are configured with the same distance and same priority.

To configure ECMP support - CLI:

```
config router bgp
    set ebgp-multipath disable[|enable]
    set ibgp-multipath disable[|enable]
    ...
end
```

Testing network configuration

Testing this configuration involves the standard connectivity checks, but also ensures that routes are being passed between protocols as expected.

Check the routing table on the FortiGate to ensure that routes from both OSPF and BGP are present.

Check the routing table on devices on the OSPF network for routes redistributed from BGP. Also, check those devices for connectivity to the Internet.

Check the routing table on Peer 2 to ensure that no routes from Peer 1 are present, but routes from the internal OSPF network are present.

For help with troubleshooting, see ["Troubleshooting BGP" on page 2201](#).

IS-IS

Intermediate System to Intermediate System Protocol (IS-IS) allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) that isn't intended to be used between Autonomous Systems (AS).

IS-IS was developed by Digital Equipment Corporation and later standardized by ISO in 1992 as ISO 19589 (see [RFC 1142](#), note that this RFC is different from the ISO version). About the same time, the Internet Engineering Task Force developed OSPF (see ["OSPF" on page 2146](#)). After the initial version, IP support was added to IS-IS and this version was called Integrated IS-IS (see [RFC 1195](#)). Its widespread use started when an early version of IS-IS was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by IS-IS, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

IS-IS is a link state protocol that is well-suited to smaller networks. It's in widespread use and has near universal support on routing hardware. It's quick to configure and works well if there are no redundant paths. However, IS-IS updates are sent out node-by-node, so it can be slow to find a path around network outages. IS-IS also lacks good authentication, can't choose routes based on different quality of service methods, and can create network loops if you're not careful. IS-IS uses Dijkstra's algorithm to find the best path, like OSPF.

While OSPF is more widely known, IS-IS is a viable alternative to OSPF in enterprise networks and ISP infrastructures, largely due to its native support for IPv6 and its non-disruptive methods for splitting, merging, migrating, and renumbering network areas.

FortiGate supports IS-IS for IPv4 and IPv6.

How IS-IS works

As one of the original modern dynamic routing protocols, IS-IS is straightforward. Its routing algorithm isn't complex, there are some options to allow fine-tuning, and it's straightforward to configure IS-IS on a FortiGate.

From [RFC 1142](#):

The routing algorithm used by the Decision Process is a shortest path first (SPF) algorithm.

Instances of the algorithm are run independently and concurrently by all intermediate systems in a routing domain. IntraDomain routing of a PDU occurs on a hop-by-hop basis: that is, the algorithm determines only the next hop, not the complete path, that a data PDU will take to reach its destination.

IS-IS versus static routing

IS-IS was one of the earliest dynamic routing protocols to work with IP addresses. As such, it's not as complex as more recent protocols. However, IS-IS is a big step forward from simple static routing.

While IS-IS may be slow in response to network outages, static routing has zero response. The same is true for convergence: static routing has zero convergence. Both IS-IS and static routing have a limited hop count, so it's not a strength or a weakness.

TLV

IS-IS uses type-length-value (TLV) parameters to carry information in Link-State PDUs (LSPs). Each IS-IS LSP consists of a variable-length header to which TLVs are appended in order to extend IS-IS for IP routing. The TLV field consists of one octet of type (T), one octet of length (L), and "L" octets of value (V). They're included in all of the IS-IS ["Packet types" on page 2227](#). For a complete breakdown of the LSP, see ["LSP structure" on page 2225](#).

In IS-IS, TLVs are used to determine route-leaking and authentication and are also used for IPv4 and IPv6 awareness and reachability.

- To determine which TLVs are responsible for route-leaking, see ["Default routing" on page 2227](#).
- To determine which TLVs are responsible for authentication, see ["Authentication" on page 2230](#).

For a complete list of reserved TLV codepoints, refer to [RFC 3359](#).

LSP structure

It's difficult to fully understand a routing protocol without knowing what information is carried in its packets. Knowing how routers exchange each type of information will help you better understand the IS-IS protocol and will allow you to configure your network more appropriately.

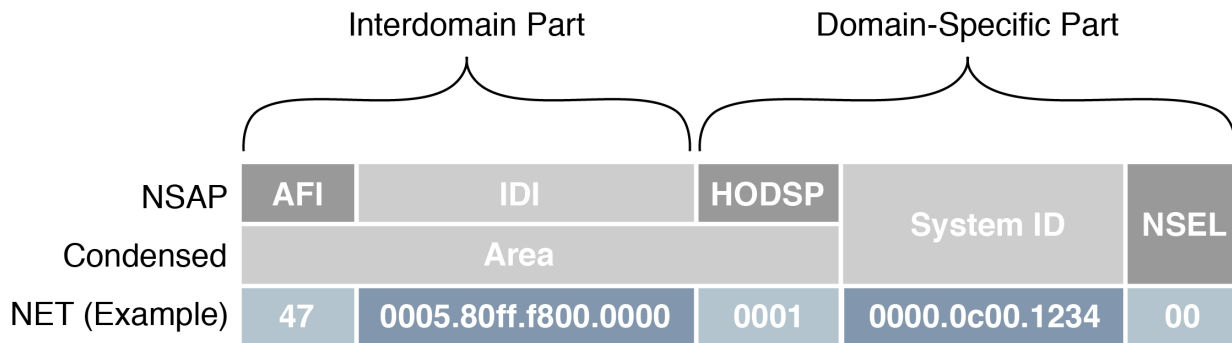

This section provides information about the contents of the IS-IS LSP. LSPs describe the network topology and can include IP routes and checksums.

NSAP and NET

IS-IS routing protocol utilizes ISO network addressing to identify network interfaces. The addresses are known as Network Service Access Points (NSAP). In general, IS-IS routers consist of only one NSAP, whereas IP addressing requires one IP address per interface.

In IS-IS, the NSAP address is translated into a Network Entity Title (NET), which is the same as the NSAP but can differentiate end systems by way of a byte called the n-selector (NSEL). In order for adjacencies to form in IS-IS, the NSEL must be set to zero, to indicate "this system". The total NET can be anywhere between 8 and 20 bytes long due to the support for variable length area addressing.

The following diagram identifies the individual parts of the NSAP, with explanations below:

NSAP and NET example

- **AFI** : The Authority and Format Identifier (AFI) specifies the format of the addressing family used. IS-IS is designed to carry routing information for several different protocols. Each entry has an address family identifier that identifies the globally unique Interdomain Part (IDP). For example, 49 is the AFI for private addresses, whereas 47 is the AFI for international organizations.
- **IDI**: The Initial Domain Identifier (IDI) identifies the routing domain within an interconnected network. The length of the IDI is typically determined by the AFI. If you are using an AFI of 49, you don't need to specify an IDI since the network is private.
- **HODSP** : The High Order Domain-Specific Part (HODSP) identifies the unique address within a specific routing domain. Together, the AFI, IDI, and HODSP define the area address. All of the nodes within an area must have the same area address.
- **System ID** : The *System ID* represents the 6-8 byte router identifier. The ID could be Media Access Control (MAC) format, as in the example above, or a static length IP address expressed in binary-coded decimal (BCD) format.
- **NSEL**: The *n-selector* (*NSEL*), as previously described, identifies the network layer transport service and must always be set to zero for IS-IS NETs.

Parts and terminology of IS-IS

Before you can understand how IS-IS functions, you need to understand some of the main concepts and parts of IS-IS.

DIS election and pseudonode LSP

In IS-IS routing protocol, a single router is chosen to be the designated intermediate system (DIS). The election of the DIS is determined automatically and dynamically on the LAN depending on highest interface priority and the subnetwork point of attachment (SNPA). The FortiGate is typically the DIS, and each router in its LAN is an intermediate system (IS).

Unlike OSPF, which elects a designated router (DR) and backup designated router (BDR), the DIS has no backup and determines the election of a new DIS whenever a router is added to the LAN or whenever the current DIS drops. A backup DIS is irrelevant since all of the routers on an IS-IS system are synchronized, and the short Hello interval used by the DIS quickly detects failures and the subsequent replacement of the DIS.

Synchronization of all the nodes in an IS-IS area could prove troublesome when updating the network infrastructure and would demand ever-increasing resources each time a new router is added (at an exponential scale). For this purpose, the DIS creates a pseudonode, which is essentially a virtual, logical node representing the LAN. The pseudonode requests adjacency status from all the routers in a multi-access network by sending IS-IS Hello (IIH) PDUs to Level 1 and Level 2 routers (where Level 1 routers share the same address as the DIS and

Level 2 routers do not). Using a pseudonode to alter the representation of the LAN in the link-state database (LSDB) greatly reduces the amount of adjacencies that area routers have to report. In essence, a pseudonode *collapses* a LAN topology, which allows a more linear scale to link-state advertising.

In order to maintain the database synchronization, the DIS periodically sends complete sequence number packets (CSNPs) to all participating routers.

Packet types

Four general packet types (PDUs) are communicated through IS-IS, appearing at both Level 1 and Level 2. They are described below.

- **Intermediate System-to-Intermediate System Hello (IIH) PDU** : As mentioned previously, the IIH PDU, or Hello packet, detects neighboring routers and indicates to the pseudonode the area's adjacency mesh. The Hello packet, flooded to the multicast address, contains the system ID of the sending router, the holding time, the circuit type of the interface on which the PDU was sent, the PDU length, the DIS identifier, and the interface priority (used in DIS election). The Hello packet also informs its area routers that it is the DIS. Hello packets are padded to the maximum IS-IS PDU size of 1492 bytes (the full MTU size) to assist in the detection of transmission errors with large frames or with MTU mismatches between adjacencies. The DIS typically floods Hello packets to the entire LAN every three seconds.
- **Link-state PDU (LSP)** : The LSP contains information about each router in an area and its connected interfaces. LSPs are refreshed periodically and acknowledged on the network by way of sequence number PDUs. If new LSP information is found, based on the most recent complete sequence number PDU (CSNP), out-of-date entries in the link-state database (LSDB) are removed and the LSDB is updated. For a more detailed breakdown of the LSP, see ["LSP structure" on page 2225](#).
- **Complete sequence number PDU (CSNP)**: CSNPs contain a list of all LSPs in the current LSDB. The CSNP informs other area routers of missing or outdated links in the adjacency mesh. The receiving routers then use this information to update their own database to ensure that all area routers converge. In contrast to Hello packets, CSNPs are sent every ten seconds and only between neighbors. In other words, they're never flooded.
- **Partial sequence number PDU (PSNP)** : PSNPs are used to request and acknowledge LSP information from an adjacency. When a router compares a CSNP with its local database and determines a discrepancy, the router requests an updated LSP using a PSNP. Once received, the router stores the LSP in its local database and responds to the DIS with acknowledgement.

Default routing

The default route is used if there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

By default, all routes are displayed in the Routing Monitor list. To display the routes in the routing table, go to **Monitor > Routing Monitor**.

Route leaking

Route leaking is a term that's used to describe the bidirectional flow of information between internal and external routing interfaces. By default, IS-IS leaks routing information from a Level 1 area into a Level 2 area. In order to leak Level 2 routing information into a Level 1 area, you must configure an export policy. The ATT bit uses Type

Level Value (TLV) 128 (for internal reachability) and TLV 130 (for external IP address information) to determine whether or not a route is leaked. For more information about TLVs, see ["Troubleshooting IS-IS" on page 2231](#).

To configure IS-IS route leaking - CLI:

- On a Level 1-2 router:

```
config router isis
    set {redistribute-l2|redistribute6-l2} enable
end
```

- On a Level 1 router:

```
config router isis
    get router {info|info6} routing-table isis
    get router {info|info6} isis route
end
```

Default information originate

You can enable the default-information-originate option to generate and advertise a default route into the FortiGate device's IS-IS-enabled networks. The generated route may be based on routes that the FortiGate learns through a dynamic routing protocol, routes in the routing table, or both. IS-IS doesn't create the default route unless you use the `always` option.

If you experience any issues or if you wish to advertise your own static routes into IS-IS updates, set this to `disable`.

To enable the default information originate option - CLI:

```
config router isis
    set {default-originate | default-originate6}
end
```

Timer options

IS-IS uses various timers to regulate its performance, including garbage, update, and timeout timers. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations. If you change these settings, ensure that the new settings are compatible with local routers and access servers.

To configure the IS-IS timers - CLI:

```
config router isis
    set garbage-timer
    set update-timer
    set timeout-timer
end
```

You will find more information on each timer below.

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There's some randomness added to help prevent network traffic congestion, which could result from all routers

simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, or you'll experience an error.

If you're experiencing significant traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you'll experience timeouts that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the DIS will keep a reachable route in the routing table while no updates for that route are received. If the DIS receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period, or you'll experience an error.

If you're experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods. It may be a considerable amount of time before the DIS is done waiting for all the timers to expire on unresponsive routes.

Garbage timer

The garbage timer is the amount of time (in seconds) that the DIS will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This results in a smaller routing table, which is useful if you have a very large network or if your network changes frequently.

IS-IS interface advertisements

You can use the `adv-passive-only` CLI command to configure which IS-IS interfaces the FortiGate advertises. If you set this command to enable, the FortiGate advertises only passive interfaces. If you set this to disable, the FortiGate advertises all IS-IS enabled interfaces.

To configure IS-IS interface advertisements - CLI:

```
config route isis
  set {adv-passive-only|adv-passive-only6} {enable | disable}
end
```

Loopback interfaces

You can configure loopback interfaces to run IS-IS.

To configure loopback interfaces to run IS-IS - CLI:

```
config router isis
  config isis-interface
    edit <name>
      set network-type loopback
    end
  end
end
```

Authentication

In routing protocols, it's typically desirable to establish authentication rules that prevent malicious and otherwise unwanted information from being injected into the routing table. IS-IS routing protocol utilizes TLV 10 to establish authentication. For more information about TLVs, see ["TLV" on page 2225](#).

Initially, IS-IS used plain cleartext to navigate the authentication rules, but this was found to be insecure since the cleartext packets were unencrypted and could be exposed to packet sniffers. As per [RFC 3567](#), HMAC-MD5 and enhanced cleartext authentication features were introduced in IS-IS, both of which encrypt authentication data, making them considerably more secure than using plain cleartext authentication.

HMAC-MD5 authentication

Hashed Message Authentication Codes - Message Digest 5 (HMAC-MD5) is a mechanism for applying a cryptographic hash function to the message authentication process. It is applied at both Level 1 and Level 2 routing. In IS-IS, an HMAC-MD5 can be applied to each type of LSP, on different interfaces, and with different passwords.

Authentication data is hashed using an AH (Authentication Header) key. From [RFC 2085](#):

The "AH Key" is used as a shared secret between two communicating parties. The Key is not a "cryptographic key" as used in a traditional sense. Instead, the AH key (shared secret) is hashed with the transmitted data and thus, assures that an intervening party cannot duplicate the authentication data. [...] Implementation should, and as frequently as possible, change the AH key. Keys need to be chosen at random, or generated using a cryptographically strong pseudo-random generator seeded with a random seed."

Cleartext authentication uses the configuration commands `area-password` and `domain-password` for authentication, but when migrating from cleartext authentication to HMAC-MD5, these command settings are automatically overwritten.

By the year 2005, the MD5 hash function had been identified as vulnerable to collision search attacks and various weaknesses. While such vulnerabilities don't compromise the use of MD5 within HMAC, administrators need to be aware of potential developments in cryptanalysis and cryptographic hash functions in the likely event that the underlying hash function needs to be replaced.

Enhanced cleartext authentication

Enhanced cleartext authentication is an extension to cleartext authentication that allows the encryption of passwords as they are displayed in the configuration. It includes a series of authentication mode commands and an authenticating key chain, and allows for more simple password modification and password management. Enhanced cleartext authentication also provides for smoother migration to and from changing authentication types. Intermediate systems continue to use the original authentication method until all the area routers are updated to use the new method.

Authentication key chain

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. A router migrates from one key to the next according to the scheduled send and receive lifetimes. If an active key is unavailable, the PDU is automatically discarded.

From [RFC 5310](#):

It should be noted that the cryptographic strength of the HMAC depends upon the cryptographic strength of the underlying hash function and on the size and quality of the key.

Troubleshooting IS-IS

Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there's a routing loop, that normal path doubles back on itself which creates a loop. When there are loops, the network has problems.

A routing loop occurs when a normally functioning network has an outage and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it's possible for a route to be attempted that involves going back a hop and trying a different hop forward. If that hop forward is also blocked by the outage, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on the affected routers. The worst part is, this situation will continue until the network administrator changes the router settings or the downed routers come back online.

Routing loop effect on the network

In addition to this “traffic jam” of routed packets, every time the routing table for a router changes, that router sends an update out to all of the IS-IS routers connected to it. In a network loop, it's possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How to spot a routing loop

Any time network traffic slows down, you'll ask yourself if it's a network loop or not. Often slowdowns are normal. They're not a full stoppage and normal traffic resumes in a short period of time.

If the slowdown is a full halt of traffic, or a major slowdown doesn't return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- [Checking your logs](#)
- [Using SNMP network monitoring](#)
- [Using link health monitoring](#)
- [Looking at the packet flow](#)

If you're not running SNMP or link health monitoring, or if you have Fortinet routers that aren't Fortinet products in your network, you can use networking tools, such as ping and traceroute, to define the outage on your network and begin to fix it.

Checking your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On the FortiGate, go to **Log & Report > Log & Archive Access**. You'll want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to link health monitoring), and other similar system events.

Once you've found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensic analysis can better help you prepare for next time.

Using SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it's located, as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops - GUI:

1. Go to **System > Config > SNMP**.
2. Enable **SNMP Agent**.
3. Optionally, enter the **Description**, **Location**, and **Contact** information for this device for easier location of the problem report.
4. In either **SNMP v1/v2c** section or **SNMP v3** section, as appropriate, select **Create New**.
5. Enter the **Community Name** that you want to use.
6. In **Hosts**, select **Add** to add an IP address where you will be monitoring the FortiGate. You can add up to 8 different addresses.
7. Ensure that ports 161 and 162 (SNMP queries and traps) are allowed through your security policies.
8. In **SNMP Event**, select the events you want to be notified about. For routing loops, this should include **CPU Overusage**, **Memory Low**, and possibly **Log disk space low**. If there are problems, the log will fill up quickly, and the FortiGate device's resources will be overused.
9. Select **OK**.
10. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate. Typically, you can configure this software to alert you about outages or CPU spikes that may indicate a routing loop.

Using link health monitoring

Another tool available to you on a FortiGate is the link health monitor. You can detect possible routing loops with link health monitors. You can configure the FortiGate to ping a gateway at regular intervals to ensure it's online and working. When the gateway isn't accessible, that interface is marked as down.

For more information about link health monitoring, see ["Link health monitor" on page 2025](#).

Looking at the packet flow

If you want to see what is happening on your network, look at the packets traveling on the network. In this situation, you're looking for routes that have metrics higher than 15, since that indicates that they're unreachable. Ideally, if you debug the flow of the packets and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you've mapped the problem on your network and determined it's in fact a routing loop, there are a number of steps you can take to correct it.

1. Get any offline routers back online. This may be a simple reboot or you may have to replace hardware. Often, this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Split horizon and poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let us call them routerA, routerB, and routerC. RouterA is linked only to routerB, routerC is linked only to routerB, and routerB is linked to both routerA and routerC. To get to routerC, routerA must go through routerB. If the link to routerC goes down, it's possible that routerB will try to use routerA's route to get to routerC. This route is A-B-C, so it won't work. However, if routerB tries to use it, this begins an endless loop. This situation is called a split horizon because from routerB's point of view, the horizon stretches out in each direction but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that can't use it. In IS-IS, this means that route is marked with a distance of 16.

Simple IS-IS example

This is an example of a typical medium-sized network configuration using IS-IS routing.

Imagine a company with four FortiGate devices connected to one another. A FortiGate at one end of the network connects to two routers, each with its own local subnet. One of these routers uses OSPF and the other router uses RIP.

Your task is to configure the four FortiGate devices to route traffic and process network updates using IS-IS, so that the farthest FortiGate (see 'FGT4' in ["Network layout and assumptions" on page 2234](#)) receives route updates for the two routers at the opposite end of the network. Furthermore, FGT4 has been given a loopback subnet that must be identified by the router running RIP.

Since the internal networks use OSPF and RIP, those protocols need to be redistributed throughout the IS-IS network. To keep the example simple, there will be no authentication of router traffic.

With IS-IS properly configured in this example, if a router fails or temporarily goes offline, the route change will propagate throughout the system.

Network layout and assumptions

Routing domains

IP scheme and interfaces

- It's assumed that each FortiGate is operating in NAT mode, running FortiOS 4.0MR2+.
- All interfaces have been previously assigned and no static routes are required.

- The Authority and Format Identifier (AFI) used is 49 : Locally administered (private).
- The Area identifiers are 0048 and 0049.

Expectations

- FGT4 must get the IS-IS route updates for RTR1 and RTR2 local subnets (10.1.1.0, 10.2.2.0, 10.3.3.0, 10.4.4.0).
- RTR1 must receive (via RIP2) the loopback subnet of FGT4 (10.60.60.1/32).

CLI configuration

The following CLI configuration occurs on each FortiGate (as identified), including only the relevant parts.

FGT1

```
config router isis
  config isis-interface
    edit "port3"
      set circuit-type level-1
      set network-type broadcast
      set status enable
    next
  end
  config isis-net
    edit 1
      set net 49.0048.1921.6818.2136.00
    next
  end
  config redistribute "connected"
  end
  config redistribute "rip"
    set status enable
    set level level-1
  end
  config redistribute "ospf"
    set status enable
    set level level-1
  end
end
config router rip
  config interface
    edit "port2"
      set receive-version 2
      set send-version 2
    next
  end
  config network
    edit 1
      set prefix 10.10.10.0 255.255.255.0
    next
  end
  config redistribute "isis"
    set status enable
  end
end
```

FGT2

```
config router isis
config isis-interface
edit "port3"
set circuit-type level-1
set network-type broadcast
set status enable
next
edit "port2"
set network-type broadcast
set status enable
next
end
config isis-net
edit 1
set net 49.0048.1221.6818.2110.00
next
end
set redistribute-l1 enable
set redistribute-l2 enable
end
```

FGT3

```
config router isis
set is-type level-2-only
config isis-interface
edit "wan1"
set network-type broadcast
set status enable
next
edit "dmz1"
set network-type broadcast
set status enable
next
end
config isis-net
edit 1
set net 49.0048.1921.6818.2108.00
next
edit 2
set net 49.0049.1921.6818.2108.00
next
end
end
```

FGT4

```
config router isis
set is-type level-2-only
config isis-interface
edit "wan1"
set network-type broadcast
set status enable
```

```

        next
    end
    config isis-net
        edit 1
            set net 49.0049.1721.0160.1004.00
        next
    end
    config redistribute "connected"
        set status enable
    end
end

```

Verification

Once the network has been configured, you need to test that it works as expected. Use the following CLI commands on the devices indicated.

Verifying if RTR1 receives loopback subnet of FGT4

```
(RTR1) # get router info routing-table all
```

Result:

```

C    10.1.1.0/24 is directly connected, vlan1
C    10.2.2.0/24 is directly connected, vlan2
C    10.10.10.0/24 is directly connected, dmz1
R    10.40.40.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R    10.50.50.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R    10.60.60.1/32 [120/2] via 10.10.10.1, dmz1, 00:04:07

```

(*) If required, filtering out 10.50.50.0 and 10.40.40.0 from the routing table could be done with a route-map.

Verification on FGT2, which is the border between L1 and L2 routing levels, looking at IS-IS information

```
FGT2 # get router info isis interface
```

Result:

```

```

Troubleshooting

The following diagnose commands are available for further IS-IS troubleshooting and will display all IS-IS activity (sent and received packets):

```
FGT # diagnose ip router isis level info
FGT # diagnose ip router isis all enable
FGT # diagnose debug enable
```

...to stop the debug type output:

```
FGT # diagnose ip router isis level none
```

Output and interpretation depends on the issue faced. You can provide this information to TAC if you open a support ticket.

Multicast forwarding

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on.

Also, RIPv2 uses multicasting to share routing table information, OSPF uses multicasting to send hello packets and routing updates, Enhanced Interior Gateway Routing Protocol (EIGRP) uses multicasting to send routing information to all EIGRP routers on a network segment and the Bonjour network service uses multicasting for DNS.

A FortiGate can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGate devices support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973) and can service multicast servers or receivers on the network segment to which a FortiGate interface is connected. Multicast routing isn't supported in transparent mode (TP mode).

To support PIM communications, the sending and receiving applications and all connecting PIM routers in between must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, either sparse mode or dense mode must be enabled on the PIM-router interfaces. Sparse mode routers can't send multicast messages to dense mode routers. In addition, if a FortiGate is located between a source and a PIM router, two PIM routers, or is connected directly to a receiver, you must create a security policy manually to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one Boot Strap Router (BSR), and if sparse mode is enabled, a number of Rendezvous Points (RPs) and Designated Routers (DRs). When PIM is enabled on a FortiGate, the FortiGate can perform any of these functions at any time as configured.

Sparse mode

Initially, all candidate BSRs in a PIM domain exchange bootstrap messages to select one BSR to which each RP sends the multicast address or addresses of the multicast groups that it can service. The selected BSR chooses one RP per multicast group and makes this information available to all of the PIM routers in the domain through bootstrap messages. PIM routers use the information to build packet distribution trees, which map each multicast group to a specific RP. Packet distribution trees may also contain information about the sources and receivers associated with particular multicast groups.

When a FortiGate interface is configured as a multicast interface, sparse mode is enabled on it by default to ensure that distribution trees are not built unless at least one downstream receiver requests multicast traffic from a specific source. If the sources of multicast traffic and their receivers are close to each other and the PIM domain contains a dense population of active receivers, you may choose to enable dense mode throughout the PIM domain instead.

An RP represents the root of a non-source-specific distribution tree to a multicast group. By joining and pruning the information contained in distribution trees, a single stream of multicast packets (for example, a video feed) originating from the source can be forwarded to a certain RP to reach a multicast destination.

Each PIM router maintains a Multicast Routing Information Base (MRIB) that determines to which neighboring PIM router join and prune messages are sent. An MRIB contains reverse-path information that reveals the path of a multicast packet from its source to the PIM router that maintains the MRIB.

To send multicast traffic, a server application sends IP traffic to a multicast group address. The locally elected DR registers the sender with the RP that is associated with the target multicast group. The RP uses its MRIB to forward a single stream of IP packets from the source to the members of the multicast group. The IP packets are replicated only when necessary to distribute the data to branches of the RP distribution tree.

To receive multicast traffic, a client application can use Internet Group Management Protocol (IGMP) version 1 (RFC 1112), 2 (RFC 2236), or 3 (RFC 3376) control messages to request the traffic for a particular multicast group. The locally elected DR receives the request and adds the host to the multicast group that's associated with the connected network segment by sending a join message towards the RP for the group. Afterward, the DR queries the hosts on the connected network segment continually to determine whether the hosts are active. When the DR no longer receives confirmation that at least one member of the multicast group is still active, the DR sends a prune message towards the RP for the group.

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601: Protocol Independent Multicast - Sparse Mode (PIM-SM). You can use the following CLI commands to configure IPv6 PIM sparse multicast routing:

```
config router multicast6
  set multicast-routing {enable | disable}
  config interface
    edit <interface-name>
      set hello-interval <1-65535 seconds>
      set hello-holdtime <1-65535 seconds>
    end
  config pim-sm-global
    config rp-address
      edit <index>
        set ipv6-address <ipv6-address>
      end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

Dense mode

The packet organization used in sparse mode is also used in dense mode. When a multicast source begins to send IP traffic and dense mode is enabled, the closest PIM router registers the IP traffic from the multicast source (S) and forwards multicast packets to the multicast group address (G). All PIM routers initially broadcast the multicast packets throughout the PIM domain to ensure that all receivers that have requested traffic for multicast group address G can access the information, if needed.

To forward multicast packets to specific destinations afterward, the PIM routers build distribution trees based on the information in multicast packets. Upstream PIM routers depend on prune/graft messages from downstream PIM routers to determine if receivers are actually present on directly-connected network segments. The PIM

routers exchange state refresh messages to update their distribution trees. FortiGate devices store this state information in a Tree Information Base (TIB), which is used to build a multicast forwarding table. The information in the multicast forwarding table determines whether packets are forwarded downstream. The forwarding table is updated whenever the TIB is modified.

PIM routers receive data streams every few minutes and update their forwarding tables using the source (S) and multicast group (G) information in the data stream. Superfluous multicast traffic is stopped by PIM routers that don't have downstream receivers. PIM routers that don't manage multicast groups send prune messages to the upstream PIM routers. When a receiver requests traffic for multicast address G, the closest PIM router sends a graft message upstream to begin receiving multicast packets.

FortiGate devices operating in NAT mode can also be configured as multicast routers. You can configure a FortiGate to be a Protocol Independent Multicast (PIM) router operating in Sparse Mode (SM) or Dense Mode (DM).

PIM support

You can configure a FortiGate to support PIM by going to **Network > Multicast** in the FortiGate GUI and enabling multicast routing. You can also enable multicast routing using the `config router multicast` CLI command. When PIM is enabled, the FortiGate allocates memory to manage mapping information. The FortiGate communicates with neighboring PIM routers to acquire mapping information and, if required, processes the multicast traffic associated with specific multicast groups.

The end-user multicast client-server applications must be installed and configured to initiate Internet connections and handle broadband content such as audio and video information.

Client applications send multicast data by registering IP traffic with a PIM-enabled router. An end user can type in a class D multicast group address, an alias for the multicast group address, or a conference call number to initiate the session.

Rather than sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use the one multicast group address to forward multicast packets to multiple destinations. Because one destination address is used, a single stream of data can be sent. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them. End users can use phone books, a menu of ongoing or future sessions, or some other method through a user interface to select the address of interest.

A class D address in the 224.0.0.0 to 239.255.255.255 range may be used as a multicast group address, subject to the rules assigned by the Internet Assigned Numbers Authority (IANA). All class D addresses must be assigned in advance. Because there isn't a way to determine in advance if a certain multicast group address is in use, collisions may occur (to resolve this problem, end users may switch to a different multicast address).

To configure a PIM domain

1. If you'll be using sparse mode, determine appropriate paths for multicast packets.
2. Make a note of the interfaces that will be PIM-enabled. These interfaces may run a unicast routing protocol.
3. If you'll be using sparse mode and want multicast packets to be handled by specific (static) RPs, record the IP addresses of the PIM-enabled interfaces on those RPs.
4. Enable PIM version 2 on all participating routers between the source and receivers. On FortiGate devices, use the `config router multicast` command to set global operating parameters.

5. Configure the PIM routers that have good connections throughout the PIM domain to be candidate BSRs.
6. If sparse mode is enabled, configure one or more of the PIM routers to be candidate RPs.
7. If required, adjust the default settings of PIM-enabled interfaces.

Multicast forwarding and FortiGate devices

In both transparent mode and NAT mode, you can configure FortiGate devices to forward multicast traffic.

For a FortiGate to forward multicast traffic, you must add FortiGate multicast security policies. Basic multicast security policies accept any multicast packets at one FortiGate interface and forward the packets out another FortiGate interface. You can also use multicast security policies to be selective about the multicast traffic that's accepted, based on source and destination address, and to perform NAT on multicast packets.

In the example shown below, a multicast source on the marketing network with IP address 192.168.5.18 sends multicast packets to the members of network 239.168.4.0. At the FortiGate, the source IP address for multicast packets originating from workstation 192.168.5.18 is translated to 192.168.18.10. In this example, the FortiGate isn't acting as a multicast router.

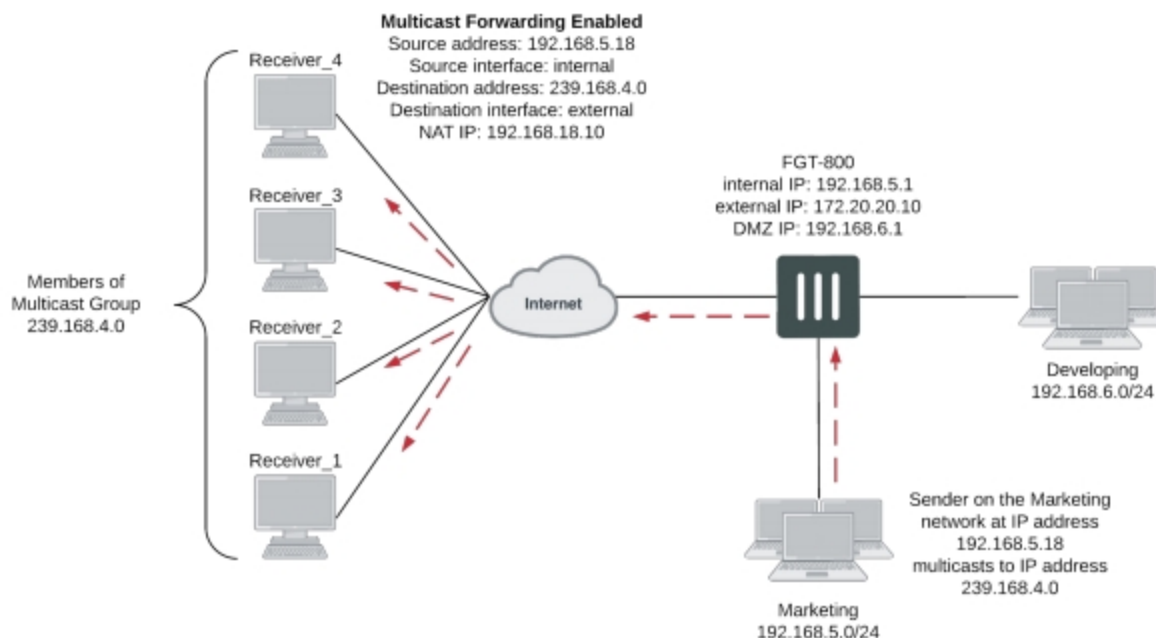

Multicast forwarding and RIPv2

RIPv2 uses multicast to share routing table information. If a FortiGate is installed on a network that includes RIPv2 routers, you must configure the FortiGate to forward multicast packets so that RIPv2 devices can share routing data through the FortiGate. No special FortiGate configuration is required to share RIPv2 data, you can simply use the information in the following sections to configure the FortiGate to forward multicast packets.

RIPv1 uses broadcasting to share routing table information. To allow RIPv1 packets through a FortiGate, you can add standard security policies. Security policies to accept RIPv1 packets can use the ANY predefined firewall service or the RIP predefined firewall service.

Example multicast network including a FortiGate that forwards multicast packets

Configuring FortiGate multicast forwarding

You configure FortiGate multicast forwarding in the CLI. Two steps are required:

1. Add multicast security policies
2. Enable multicast forwarding

This second step is required only if a FortiGate is operating in NAT mode. If the FortiGate is operating in transparent mode, adding a multicast policy enables multicast forwarding.

There's sometimes confusion between the terms “forwarding” and “routing”. These two functions shouldn't be taking place at the same time.

It's mentioned that multicast-forward should be enabled when the FortiGate is in NAT mode and that this will forward any multicast packet to all interfaces. However, this parameter shouldn't be enabled when the FortiGate operates as a multicast router (for example, with a routing protocol enabled). It should only be enabled when there's no routing protocols activated.

Adding multicast security policies

You need to add security policies to allow packets to pass from one interface to another. Multicast packets require multicast security policies. You add multicast security policies from the CLI using the `config firewall multicast-policy` command. As with unicast security policies, you specify the source and destination interfaces and, optionally, the allowed address ranges for the source and destination addresses of the packets.

You can also use multicast security policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast security policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- Source and destination interfaces are optional. If left blank, the multicast will be forwarded to ALL interfaces.
- Source and destination addresses are optional. If left unset, it means ALL addresses.
- The `nat` keyword is optional. Use it when source address translation is needed.

Enabling multicast forwarding

Multicast forwarding is enabled by default. In NAT mode you must use the `multicast-forward` keyword of the `system settings` CLI command to enable or disable multicast forwarding. When `multicast-forward` is enabled, a FortiGate forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add security policies to actually allow multicast packets through the FortiGate. In our example, the security policy allows multicast packets received by the internal interface to exit to the external interface.

Enabling multicast forwarding is only required if a FortiGate is operating in NAT mode. If a FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

To enable multicast forwarding - CLI:

```
config system settings
set multicast-forward enable
```

```
end
```

If multicast forwarding is disabled and the FortiGate drops packets that have multicast source or destination addresses.

You can also use the `multicast-ttl-notchange` keyword of the `system settings` command so that the FortiGate doesn't increase the TTL value for forwarded multicast packets. You should use this option only if packets are expiring before reaching the multicast router.

```
config system settings
    set multicast-ttl-notchange enable
end
```

In transparent mode, a FortiGate doesn't forward frames with multicast destination addresses. Multicast traffic, such as the one used by routing protocols or streaming media, may need to traverse the FortiGate and shouldn't interfere with the communication. To avoid any issues during transmission, you can set up multicast security policies. These types of security policies can only be enabled using the CLI.

When you use multicast security policies, you must disable the `multicast-skip-policy` CLI parameter. To disable enter the commands:

```
config system settings
    set multicast-skip-policy disable
end
```

In this simple example, a check isn't performed on the source or destination interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

To enable the multicast policy - CLI:

```
config firewall multicast-policy
    edit 1
        set action accept
    end
```

In this example, the multicast policy only applies to the source port of WAN1 and the destination port of Internal.

To enable the restrictive multicast policy - CLI:

```
config firewall multicast-policy
    edit 1
        set srcintf wan1
        set dstintf internal
        set action accept
    end
```

In this example, packets are allowed to flow from WAN1 to Internal, and sourced by the address 172.20.120.129, which is represented by the address object "example_addr-1".

To enable the restrictive multicast policy - CLI:

```
config firewall multicast-policy
    edit 1
        set srcintf wan1
        set srcaddr example_addr-1
        set dstintf internal
        set action accept
```

```
end
```

This example shows how to configure the multicast security policy required for the configuration shown. This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address range 239.168.4.0. The policy allows the multicast packets to enter the internal interface and then exit the external interface. When the packets leave the external interface, their source address is translated to 192.168.18.10

```
config firewall multicast-policy
edit 5
    set srcaddr 192.168.5.18 255.255.255.255
    set srcintf internal
    set destaddr 239.168.4.0 255.255.255.0
    set dstintf external
    set nat 192.168.18.10
end
```

This example shows how to configure a multicast security policy so that the FortiGate forwards multicast packets from a multicast server with an IP 10.10.10.10 is broadcasting to address 225.1.1.1. This server is on the network connected to the FortiGate DMZ interface.

```
config firewall multicast-policy
edit 1
    set srcintf DMZ
    set srcaddr 10.10.10.10 255.255.255.255
    set dstintf Internal
    set dstaddr 225.1.1.1 255.255.255.255
    set action accept
edit 2
    set action deny
end
```

Displaying IPv6 multicast router information

You can use the following CLI command to display IPv6 multicast router information (equivalent to the IPv4 version of the command):

```
get router info6 multicast
```

Multicast routing examples

This section contains the following multicast routing configuration examples and information:

- Example FortiGate PIM-SM configuration using a static RP
- FortiGate PIM-SM debugging examples
- Example multicast destination NAT (DNAT) configuration
- Example PIM configuration that uses BSR to find the RP

Example FortiGate PIM-SM configuration using a static RP

The example Protocol Independent Multicast Sparse Mode (PIM-SM) configuration shown below has been tested for multicast interoperability using PIM-SM between Cisco 3750 switches running 12.2 and a FortiGate-800 running FortiOS v3.0 MR5 patch 1. In this configuration, the receiver receives the multicast stream when it joins the group 233.254.200.1.

Example: FortiGate PIM-SM topology

The configuration uses a statically configured rendezvous point (RP) which resides on the Cisco_3750_1. Using a bootstrap router (BSR) wasn't tested in this example. See "Example PIM configuration that uses BSR to find the RP" for an example that uses a BSR.

Configuration steps

The following procedures show how to configure the multicast configuration settings for the devices in the example configuration.

- Cisco_3750_1 router configuration
- Cisco_3750_2 router configuration
- To configure the FortiGate-800 unit
- Cisco_3750_3 router configuration

Cisco_3750_1 router configuration

```
version 12.2

```

To configure the FortiGate-800 unit - GUI:

1. Configure the internal and external interfaces.

- **Internal**

Go to **Network > Interfaces**.

Select the internal interface.

Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.138.253 255.255.255.0
Administrative Access:	PING

Select **OK**.

- **External**

Go to **Network > Interfaces**.
Select the external interface.

Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.130.253 255.255.255.0
Administrative Access:	HTTPS and PING

Select **OK**.

2. Add a firewall addresses.

Go to **Policy & Objects > Addresses**.

- RP

Select **Create New**.

Use the following settings:

Category	Address
Name	RP
Type	Subnet
Subnet/IP Range	169.254.100.1/32
Interface	Any
Visibility	<enabled>

Select **OK**.

- Multicast source subnet

Select **Create New**.

Use the following settings:

Category	Address
Name	multicast_source_subnet

Type	Subnet
Subnet/IP Range	169.254.82.0/24
Interface	Any
Visibility	<enabled>

Select **OK**.

3. Add destination multicast address

Go to **Policy & Objects > Addresses**.

Select **Create New**.

Use the following settings:

Category	Multicast Address
Name	Multicast_stream
Type	Broadcast Subnet
Broadcast Subnet	233.254.200.0/24
Interface	Any
Visibility	<enabled>

Select **OK**.

4. Add standard security policies to allow traffic to reach the RP.

Go to **Policy & Objects > IPv4 Policy**.

- 1st policy

Select **Create New**.

Use the following settings:

Incoming Interface	internal
Source Address	all
Outgoing Interface	external
Destination Address	RP
Schedule	always

Service	ALL
Action	ACCEPT

Select **OK**.

- 2nd policy

Select **Create New**

Use the following settings:

Incoming Interface	external
Source Address	RP
Outgoing Interface	internal
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

Select **OK**.

5. Add the multicast security policy.

Go to **Policy & Objects > Multicast Policy**.

Select **Create New**.

Use the following settings:

Incoming Interface	external
Source Address	multicast_source_subnet
Outgoing Interface	internal
Destination Address	multicast_stream
Protocol	Any
Action	ACCEPT

Select **OK**.

6. Add an access list. (CLI only)

```
config router access-list
```

```

edit Source-RP
  config rule
    edit 1
      set prefix 233.254.200.0 255.255.255.0
      set exact-match disable
    next
  end

```

7. Add some static routes.

Go to **Network > Static Routes**.

- Route 1

Select **Create New**.

Use the following settings:

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	10.31.130.250
Interface	internal
Administrative Distance	<default>
Priority	<default>

Select **OK**.

- Route 2

Select **Create New**.

Use the following settings:

Destination IP/Mask	169.254.0.0/16
Gateway	10.31.138.250
Interface	external
Administrative Distance	<default>
Priority	<default>

Select **OK**.

8. Configure multicast routing.

Go to **Network > Multicast**.

Add the following Static Rendezvous Point(s):

- 169.254.100.1
- Route 1

Select **Create New**.

Use the following settings:

Interface	internal
PIM Mode	Sparse Mode
DR Priority	<not needed in this scenario>
RP Candidate	<not needed in this scenario>
RP Candidate Priority	<not needed in this scenario>

Select **OK**.

- Route 2

Select **Create New**.

Use the following settings:

Interface	external
PIM Mode	Sparse Mode
DR Priority	
RP Candidate	
RP Candidate Priority	

Select **OK**.

Cisco_3750_3 router configuration

```

version 12.2
!
hostname Cisco-3750-3
!
switch 1 provision ws-c3750-24ts
ip subnet-zero
ip routing
!
ip multicast-routing distributed
!
spanning-tree mode pvst
no spanning-tree optimize bpdu transmission
spanning-tree extend system-id
!
interface FastEthernet1/0/23
    switchport access vlan 128
    switchport mode access
!
interface FastEthernet1/0/24

```

```

        switchport access vlan 130
        switchport mode access
    !

    !
    !
ip access-list standard Source-RP
permit 233.254.200.0 0.0.0.255

```

FortiGate PIM-SM debugging examples

Using the example topology shown below, you can trace the multicast streams and states within the three FortiGate devices (FGT-1, FGT-2, and FGT-3) using the debug commands described in this section. The command output in this section is taken from the FortiGate when the multicast stream is flowing correctly from source to receiver.

PIM-SM debugging topology

Checking that the receiver has joined the required group

From the last hop router, FGT-3, you can use the following command to check that the receiver has correctly joined the required group.

```

FGT-3 # get router info multicast igmp groups
IGMP Connected Group Membership
Group Address Interface Uptime Expires Last Reporter
239.255.255.1 port3 00:31:15 00:04:02 10.167.0.62

```

Only 1 receiver is displayed for a particular group, this is the device that responded to the IGMP query request from the FGT-3. If a receiver is active, the expire time should drop to approximately 2 minutes before being refreshed.

Checking the PIM-SM neighbors

Next, the PIM-SM neighbors should be checked. A PIM router becomes a neighbor when the PIM router receives a PIM hello. Use the following command to display the PIM-SM neighbors of FGT-3:

```
FGT-3 # get router info multicast pim sparse-mode neighbour
Neighbor Interface Uptime/Expires Ver DR
Address Priority/Mode
10.132.0.156 port2 01:57:12/00:01:33 v2 1 /
```

Checking that the PIM router can reach the RP

The rendezvous point (RP) must be reachable for the PIM router (FGT-3) to be able to send the *, G join to request the stream. This can be checked for FGT-3 using the following command:

```
FGT-3 # get router info multicast pim sparse-mode rp-mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
RP: 192.168.1.1
Uptime: 07:23:00
```

Viewing the multicast routing table (FGT-3)

The FGT-3 unicast routing table can be used to determine the path taken to reach the RP at 192.168.1.1. You can then check the stream state entries using the following commands:

```
FGT-3 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

(*,*,RP) Entries	This state may be reached by general joins for all groups served by a specified RP.
(*,G) Entries	State that maintains the RP tree for a given group.
(S,G) Entries	State that maintains a source-specific tree for source S and group G.
(S,G,rpt) Entries	State that maintains source-specific information about source s on the RP tree for G. For example, if a source is being received on the source-specific tree, it will normally have been pruned off the RP tree.
FCR	The FCR state entries are for tracking the sources in the <*, G> when <S, G> isn't available for any reason, the stream would typically be flowing when this state exists.

Breaking down each entry in detail:

```
(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: JOINED
Local:
port3
Joined:
Asserted:
FCR:
```

The RP will always be listed in a *, G entry, the RPF neighbor and interface index will also be shown. In this topology, these are the same in all downstream PIM routers. The state is active so the upstream state is joined.

In this case FGT-3 is the last hop router so the IGMP join is received locally on port3. There is no PIM outgoing interface listed for this entry as it is used for the upstream PIM join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.132.0.156
RPF idx: port2
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
Asserted:
Outgoing:
port3
```

This is the entry for the SPT, no RP IS listed. The S, G stream will be forwarded out of the stated outgoing interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: NOT PRUNED
Local:
Pruned:
Outgoing:
```

The above S, G, RPT state is created for all streams that have both a S, G and a *, G entry on the router. This isn't pruned, in this case, because of the topology: the RP and source are reachable over the same interface.

Although not seen in this scenario, assert states may be seen when multiple PIM routers exist on the same LAN, which can lead to more than one upstream router having a valid forwarding state. Assert messages are used to elect a single forwarder from the upstream devices.

Viewing the PIM next-hop table

The PIM next-hop table is also very useful for checking the various states, it can be used to quickly identify the states of multiple multicast streams.

```
FGT-3 # get router info multicast pim sparse-mode next-hop
Flags: N = New, R = RP, S = Source, U = Unreachable
Destination Type Nexthop Nexthop Metric Pref Refcnt
Num Addr Ifindex
-----
10.166.0.11 ..S. 1 10.132.0.156 9 21 110 3
192.168.1.1 .R.. 1 10.132.0.156 9 111 110 2
```

Viewing the PIM multicast forwarding table

Also, you can check the multicast forwarding table showing the ingress and egress ports of the multicast stream.

```
FGT-3 # get router info multicast table

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL threshold)

(10.166.0.11, 239.255.255.1), uptime 04:02:55, stat expires 00:02:25
Owner PIM-SM, Flags: TF
Incoming interface: port2
Outgoing interface list:
port3 (TTL threshold 1)
```

Viewing the kernel forwarding table

Also, the kernel forwarding table can be verified, however this should give similar information to the above command:

```
FGT-3 # diag ip multicast mroute
grp=239.255.255.1 src=10.166.0.11 intf=9 flags=(0x10000000)[ ] status=resolved
last_assert=2615136 bytes=1192116 pkt=14538 wrong_if=0 num_ifs=1
index(ttl)=[6(1),]
```

Viewing the multicast routing table (FGT-2)

If you check the output on FGT-2, there are some small differences:

```
FGT-2 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0

(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: JOINED
Local:
Joined:
external
Asserted:
FCR:
```

The *, G entry now has a joined interface rather than local because it received a PIM join from FGT-3 rather than a local IGMP join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.130.0.237
RPF idx: internal
SPT bit: 1
Upstream State: JOINED
```

```

Local:
Joined:
external
Asserted:
Outgoing:
external

```

The `S, G` entry shows that we have received a join on the external interface and the stream is being forwarded out of this interface.

```

(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: PRUNED
Local:
Pruned:
Outgoing:
External

```

The `S, G, RPT` is different from FGT-3 because FGT-2 is the RP, it has pruned back the SPT for the RP to the first hop router.

Viewing the multicast routing table (FGT-1)

FGT-1 again has some differences with regard to the PIM-SM states. There's no `*, G` entry because it isn't in the path of a receiver and the RP.

```

FGT-1_master # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0

```

Below the `S, G` is the SPT termination because this FortiGate is the first hop router. The RPF neighbor always shows as `0.0.0.0` because the source is local to this device. Both the joined and outgoing fields show as external because the PIM join and the stream is egressing on this interface.

```

(10.166.0.11, 239.255.255.1)
RPF nbr: 0.0.0.0
RPF idx: None
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
external
Asserted:
Outgoing:
external

```

The stream has been pruned back from the RP because the end-to-end SPT is flowing. In this case, there's no requirement for the stream to be sent to the RP.

```

(10.166.0.11, 239.255.255.1, rpt)
RP: 0.0.0.0
RPF nbr: 10.130.0.156
RPF idx: external

```

```

Upstream State: RPT NOT JOINED
Local:
Pruned:
Outgoing:

```

Example multicast DNAT configuration

The example topology shown and described below shows how to configure destination NAT (DNAT) for two multicast streams. Both of these streams originate from the same source IP address, which is 10.166.0.11. The example configuration keeps the streams separate by creating 2 multicast NAT policies.

In this example, the FortiGate devices have the following roles:

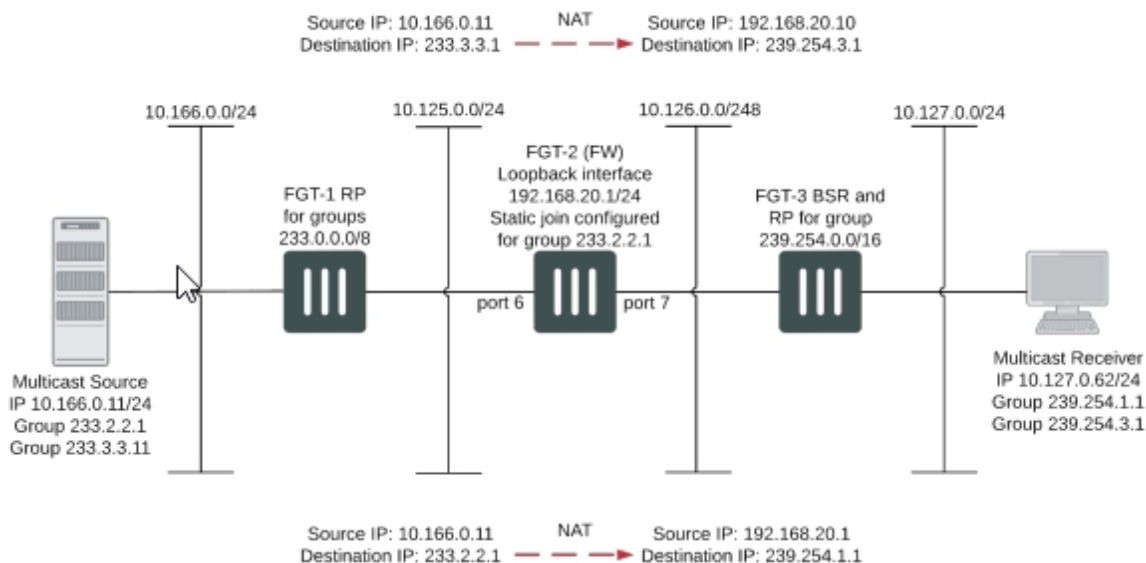

- FGT-1 is the RP for dirty networks, 233.0.0.0/8.
- FGT-2 performs all firewall and DNAT translations.
- FGT-3 is the RP for the clean networks, 239.254.0.0/16.
- FGT-1 and FGT-3 are functioning as PM enabled routers and could be replaced can be any PIM enabled router.

This example only describes the configuration of FGT-2.

FGT-2 performs NAT so that the receivers connected to FGT-3 receive the following translated multicast streams.

- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.2.2.1, FGT-3 translates the source and destination IPs to 192.168.20.1 and 239.254.1.1
- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.3.3.1, FGT-3 translates the source and destination IPs to 192.168.20.10 and 239.254.3.1

Example multicast DNAT topology

To configure FGT-2 for DNAT multicast

1. Add a loopback interface. In the example, the loopback interface is named `loopback`.

```
config system interface
```

```

edit loopback
    set vdom root
    set ip 192.168.20.1 255.255.255.0
    set type loopback
next
end

```

2. Add PIM and add a unicast routing protocol to the loopback interface as if it was a normal routed interface. Also, add static joins to the loopback interface for any groups to be translated.

```

config router multicast
config interface
edit loopback
    set pim-mode sparse-mode
    config join-group
        edit 233.2.2.1
        next
        edit 233.3.3.1
        next
    end
next

```

3. In this example, to add firewall multicast policies, different source IP addresses are required so you must first add an IP pool:

```

config firewall ippool
edit Multicast_source
    set endip 192.168.20.20
    set interface port6
    set startip 192.168.20.10
next
end

```

4. Add the translation security policies.

Policy 2, which is the source NAT policy, uses the actual IP address of port6. Policy 1, the DNAT policy, uses an address from the IP pool. The source and destination addresses will need to be previously created address objects. For this example, 233.3.3.1 255.255.255.255 will be represented by "example-addr_1" and 10.166.0.11 255.255.255.255 will be represented by "example-addr_2". You'll likely want to use something more intuitive from your own network.

```

config firewall multicast-policy
edit 1
    set dnat 239.254.3.1
    set dstaddr example-addr_1
    set dstintf loopback
    set nat 192.168.20.10
    set srcaddr example-addr_2
    set srcintf port6
next
edit 2
    set dnat 239.254.1.1
    set dstaddr 233.2.2.1 255.255.255.255
    set dstintf loopback
    set nat 192.168.20.1
    set srcaddr 10.166.0.11 255.255.255.255
    set srcintf port6
next
end

```

5. Add a firewall multicast policy to forward the stream from the loopback interface to the physical outbound interface.

This example is an any/any policy that makes sure traffic accepted by the other multicast policies can exit the FortiGate.

```
config firewall multicast-policy
  edit 3
    set dstintf port7
    set srcintf loopback
  next
end
```

Example PIM configuration that uses BSR to find the RP

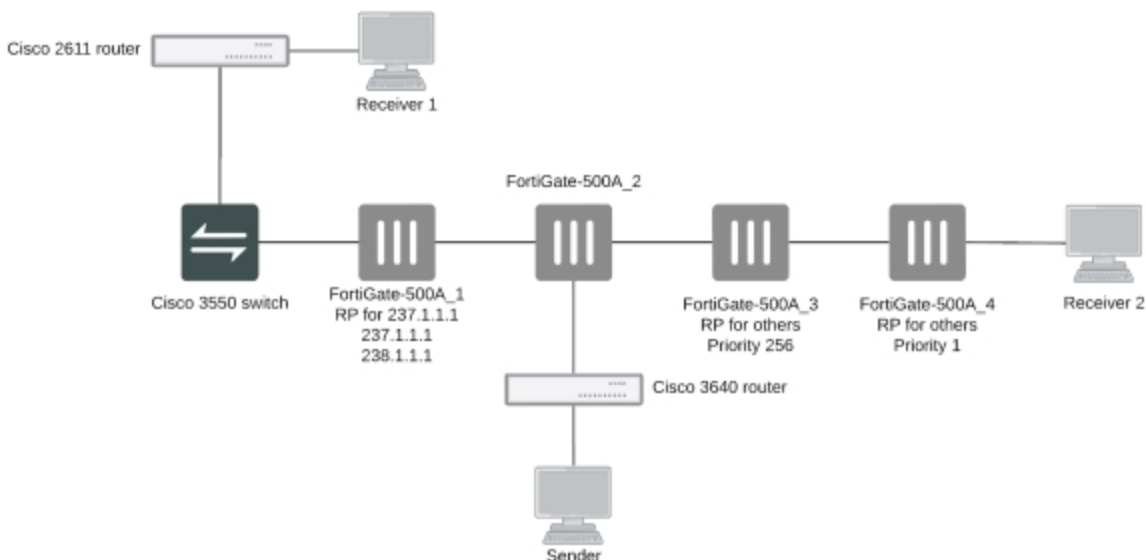

This example shows how to configure a multicast routing network for a network consisting of four FortiGate-500A devices (FortiGate-500A_1 to FortiGate-500A_4). A multicast sender is connected to FortiGate-500A_2. FortiGate-500A_2 forwards multicast packets in two directions to reach Receiver 1 and Receiver 2.

The configuration uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

This example describes:

- Commands used in this example
- Configuration steps
- Example debug commands

PIM network topology using BSR to find the RP

Commands used in this example

This example uses CLI commands for the following configuration settings:

- Adding a loopback interface (lo0)
- Defining the multicast routing
- Adding the NAT multicast policy

Adding a loopback interface

Where required, the following command is used to define a loopback interface named lo0.

```
config system interface
  edit lo0
    set vdom root
    set ip 1.4.50.4 255.255.255.255
    set allowaccess ping https ssh snmp http telnet
    set type loopback
  next
end
```

Defining the multicast routing

In this example, the following command syntax is used to define multicast routing.

The example uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface lo0 must join the 236.1.1.1 group (source).

```
config router multicast
  config interface
    edit port6
      set pim-mode sparse-mode
    next
    edit port1
      set pim-mode sparse-mode
    next
    edit lo0
      set pim-mode sparse-mode
      set rp-candidate enable
      config join-group
        edit 236.1.1.1
        next
      end
      set rp-candidate-priority 1
    next
  end
  set multicast-routing enable
  config pim-sm-global
    set bsr-allow-quick-refresh enable
    set bsr-candidate enable
    set bsr-interface lo0
    set bsr-priority 200
  end
end
```

Adding the NAT multicast policy

In this example, the incoming multicast policy does the address translation.

The NAT address should be the same as the IP address of the of loopback interface. The DNAT address is the translated address, which should be a new group.

```
config firewall multicast-policy
edit 1
set dstintf port6
set srcintf lo0
next
edit 2
set dnat 238.1.1.1
set dstintf lo0
set nat 1.4.50.4
set srcintf port1
next
```

Configuration steps

In this sample, FortiGate-500A_1 is the RP for the group 228.1.1.1, 237.1.1.1, 238.1.1.1, and FortiGate-500A_4 is the RP for the other group which has a priority of 1. OSPF is used in this example to distribute routes including the loopback interface. All firewalls have full mesh security policies to allow any to any.

- In the FortiGate-500A_1 configuration, the NAT policy translates source address 236.1.1.1 to 237.1.1.1
- In the FortiGate-500A_4 configuration, the NAT policy translates source 236.1.1.1 to 238.1.1.1
- Source 236.1.1.1 is injected into network as well

The following procedures include the CLI commands for configuring each of the FortiGate devices in the example configuration.

To configure FortiGate-500A_1

1. Configure multicast routing:

```
config router multicast
config interface
edit port5
set pim-mode sparse-mode
next
edit port4
set pim-mode sparse-mode
next
edit lan
set pim-mode sparse-mode
next
edit port1
set pim-mode sparse-mode
next
edit lo999
set pim-mode sparse-mode
next
edit lo0
set pim-mode sparse-mode
set rp-candidate enable
set rp-candidate-group 1
next
end
set multicast-routing enable
config pim-sm-global
```

```

        set bsr-candidate enable
        set bsr-interface lo0
    end
end

```

2. Add multicast security policies:

```

config firewall multicast-policy
    edit 1
        set dstintf port5
        set srcintf port4
    next
    edit 2
        set dstintf port4
        set srcintf port5
    next
    edit 3
    next
end

```

3. Add router access lists:

```

config router access-list
    edit 1
        config rule
            edit 1
                set prefix 228.1.1.1 255.255.255.255
                set exact-match enable
            next
            edit 2
                set prefix 237.1.1.1 255.255.255.255
                set exact-match enable
            next
            edit 3
                set prefix 238.1.1.1 255.255.255.255
                set exact-match enable
            next
        end
    next
end

```

To configure FortiGate-500A_2

1. Configure multicast routing:

```

config router multicast
    config interface
        edit "lan"
            set pim-mode sparse-mode
        next
    edit "port5"
        set pim-mode sparse-mode
    next
    edit "port2"
        set pim-mode sparse-mode
    next
    edit "port4"
        set pim-mode sparse-mode
    next
end

```

```
edit "lo_5"
    set pim-mode sparse-mode
    config join-group
        edit 236.1.1.1
        next
    end
next
end
set multicast-routing enable
end
```

2. Add multicast security policies:

```
config firewall multicast-policy
edit 1
    set dstintf lan
    set srcintf port5
next
edit 2
    set dstintf port5
    set srcintf lan
next
edit 4
    set dstintf lan
    set srcintf port2
next
edit 5
    set dstintf port2
    set srcintf lan
next
edit 7
    set dstintf port1
    set srcintf port2
next
edit 8
    set dstintf port2
    set srcintf port1
next
edit 9
    set dstintf port5
    set srcintf port2
next
edit 10
    set dstintf port2
    set srcintf port5
next
edit 11
    set dnat 237.1.1.1
    set dstintf lo_5
    set nat 5.5.5.5
    set srcintf port2
next
edit 12
    set dstintf lan
    set srcintf lo_5
next
edit 13
    set dstintf port1
```

```
        set srcintf lo_5
    next
    edit 14
        set dstintf port5
        set srcintf lo_5
    next
    edit 15
        set dstintf port2
        set srcintf lo_5
    next
    edit 16
    next
end
```

To configure FortiGate-500A_3

1. Configure multicast routing:

```
config router multicast
    config interface
        edit port5
            set pim-mode sparse-mode
        next
        edit port6
            set pim-mode sparse-mode
        next
        edit lo0
            set pim-mode sparse-mode
            set rp-candidate enable
            set rp-candidate-priority 255
        next
        edit lan
            set pim-mode sparse-mode
        next
    end
set multicast-routing enable
config pim-sm-global
    set bsr-candidate enable
    set bsr-interface lo0
end
end
```

2. Add multicast security policies:

```
config firewall multicast-policy
    edit 1
        set dstintf port5
        set srcintf port6
    next
    edit 2
        set dstintf port6
        set srcintf port5
    next
    edit 3
        set dstintf port6
        set srcintf lan
    next
    edit 4
        set dstintf lan
```

```
        set srcintf port6
    next
    edit 5
        set dstintf port5
        set srcintf lan
    next
    edit 6
        set dstintf lan
        set srcintf port5
    next
end
```

To configure FortiGate-500A_4

1. Configure multicast routing:

```
config router multicast
config interface
    edit port6
        set pim-mode sparse-mode
    next
    edit lan
        set pim-mode sparse-mode
    next
    edit port1
        set pim-mode sparse-mode
    next
    edit lo0
        set pim-mode sparse-mode
        set rp-candidate enable
        config join-group
            edit 236.1.1.1
            next
        end
        set rp-candidate-priority 1
    next
end
set multicast-routing enable
config pim-sm-global
set bsr-allow-quick-refresh enable
set bsr-candidate enable
set bsr-interface lo0
set bsr-priority 1
end
end
```

2. Add multicast security policies:

```
config firewall policy
    edit 1
        set srcintf lan
        set dstintf port6
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 2
```

```
        set srcintf port6
        set dstintf lan
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 3
        set srcintf port1
        set dstintf port6
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 4
        set srcintf port6
        set dstintf port1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 5
        set srcintf port1
        set dstintf lan
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 6
        set srcintf lan
        set dstintf port1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 7
        set srcintf port1
        set dstintf port1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 8
        set srcintf port6
        set dstintf lo0
        set srcaddr all
```

```
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 9
        set srcintf port1
        set dstintf lo0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 10
        set srcintf lan
        set dstintf lo0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
end
```

SD-WAN

This chapter describes FortiOS 6.0 features for SD-WAN.

Application control settings in SD-WAN rules

You can configure application control and application control groups in SD-WAN rules.

To configure application control in SD-WAN rules - GUI:

1. Go to **Network > SD-WAN Rules**.
2. Select **Create New** or **Edit** an existing rule.
3. In the **Destination** section, in **Destination type** field, select **Internet Service**.
4. In the **Select Entries** side menu, select **Application Control**.
5. Select one or more applications from the list.

To configure application control in SD-WAN rules - CLI:

```
config application group
edit <name>
    set application <application-ID-list>
next
end
```

Internet services in SD-WAN rules

Internet service support is expanded from a single Internet service to support Internet service groups, custom Internet service groups, control-based application identification, and control-based Internet service groups.

To configure Internet services in SD-WAN rules - GUI:

1. Go to **Network > SD-WAN Rules**.
2. **Create New** or **Edit** an existing rule.
3. In the **Destination** section, in **Destination type** field, select **Internet Service**.
4. In the **Select Entries** side menu, select **Internet Service**.
5. Select one or more Internet services from the list.

To configure Internet service groups in SD-WAN rules - CLI:

```
config system virtual-wan-link
config service
edit <priority-rule-ID>
    set internet-service enable
    set internet-service-group <Internet-service-group-list>
    set internet-service-custom-group <custom-Internet-service-group-list>
    set internet-service-ctrl <control-based-Internet-service-ID-list>
    set internet-service-ctrl-group <control-based-Internet-service-group-list>
next
end
```

```
end
```

To configure Internet service groups - CLI:

```
config firewall internet-service-group
  edit <Internet-service-group-name>
    set comment [string]
    set member <Internet-service-group-members>
  next
end
```

To configure custom Internet service groups - CLI:

```
config firewall internet-service-custom-group
  edit <custom-Internet-service-group-name>
    set comment [string]
    set member <custom-Internet-service-group-members>
  next
end
```

Bandwidth and custom profile options in SD-WAN rules

You can configure bandwidth options for the link cost factor, so that a FortiGate selects the link based on available bandwidth of incoming, outgoing, or bidirectional traffic. This is useful because users may use some applications primarily for downloading and other applications primarily for uploading.

You can also configure a custom profile for the link cost factor. A FortiGate selects the best link using the following formula: $\text{Link quality} = (\text{packet-loss-weight} * \text{packet loss}) + (\text{latency-weight} * \text{latency}) + (\text{jitter-weight} * \text{jitter}) + (\text{bandwidth-weight} / \text{bandwidth})$.

To configure bandwidth and custom profile options in SD-WAN rules - GUI:

1. Go to **Network > SD-WAN Rules**.
2. In the **Outgoing Interfaces** section, in the **Strategy** field, select **Best Quality**.
3. After you add interfaces in the **Interface preference** field, a **Quality criteria** field appears.
4. In the **Quality criteria** field, you can select **Downstream** for downstream bandwidth, **Upstream** for upstream bandwidth, **Bandwidth** for bidirectional bandwidth, or **custom-profile-1** to create a custom profile.
5. After you select **custom-profile-1**, you can set the **latency-weight**, **jitter-weight**, **packet-loss-weight**, and **bandwidth-weight**.

To configure bandwidth options in SD-WAN rules - CLI:

```
config system virtual-wan-link
  config service
    edit <priority-rule-ID>
      set link-cost-factor inboundwidth
      set link-cost-factor outboundwidth
      set link-cost-factor bibandwidth
    next
  end
end
```

To configure a custom profile in SD-WAN rules - CLI:

```

config system virtual-wan-link
config service
    edit <priority-rule-ID>
        set link-cost-factor custom-profile-1
        set packet-loss-weight <integer>
        set latency-weight <integer>
        set jitter-weight <integer>
        set bandwidth-weight <integer>
    next
end
end

```

where packet-loss-weight, latency-weight, jitter-weight, and bandwidth-weight are integers in the range of 0 to 10000000.

SLA management

You can configure service level agreement (SLA) management in the FortiGate GUI.

If all links meet the SLA criteria, the FortiGate uses the first link, even if that link isn't the best quality link. If at any time, the link in use doesn't meet the SLA criteria, and the next link in the configuration meets the SLA criteria, the FortiGate changes to that link. If the next link doesn't meet the SLA criteria, the FortiGate uses the next link in the configuration if it meets the SLA criteria, and so on.

If no links meet the SLA criteria, the FortiGate uses the preferred link, which is the first link in the configuration. FortiGate continually checks the links for to see if they meet the SLA criteria.

To configure SLA - GUI:

1. Go to **Network > Performance SLA**.
2. Select **Create New**.
3. In the **Name**, **Protocol**, **Server**, and **Participants** fields, set appropriate values.
4. In the **SLA Targets** section, set appropriate values in the **Latency threshold**, **Jitter threshold**, and **Packet loss threshold** fields. Select **OK**.
The Performance SLA page changes to display information about the SLA.
5. Go to **Network > SD-WAN Rules**.
6. In the **Name** field, set a name for the rule.
7. In the **Destination type** field, select **Internet Service**. In the **Destination** field, select **+**. In the **Select Entries** window, select **Internet Service** and select the appropriate Internet services from the list. Select **Close**.
8. In the **Outgoing Interfaces** section, in the **Strategy** field, select **Minimum Quality (SLA)**.
9. In the **Interface preference** field, select **+**. In the **Select Entries** window, select the appropriate interfaces from the list. Select **Close**.
10. In the **Required SLA target** field, select the appropriate SLA from the drop-down list. Select **OK**.
The SD-WAN Rules page changes to display information about the SD-WAN Rules. You can drag and drop the rules to reorder them.

To configure SLA in health checks - CLI:

```

config system virtual-wan-link

```

```

config health-check
  edit <health-check-name>
    config sla
      edit <SLA-ID>
        set link-cost-factor {latency | jitter | packet-loss}
        set latency-threshold <milliseconds>
        set jitter-threshold <milliseconds>
        set packetloss-threshold <percentage>
      next
    end
  end
end

```

To configure SLA in services - CLI:

```

config system virtual-wan-link
  config service
    edit <priority-rule-ID>
      set mode sla
      config sla
        edit <health-check-name>
          set id <SLA-ID>
        next
      end
    next
  end
end

```

To set link priority mode to SLA in SD-WAN rules - CLI:

```

config system virtual-wan-link
  config service
    edit <priority-rule-ID>
      set mode sla
      set link-cost-threshold <threshold-change-percentage>
      set priority-members <member-sequence-list>
    next
  end
end

```

Multiple server support for health checks

You can now configure multiple servers for health checks in SD-WAN.

To configure server support for health checks - CLI:

```

config system virtual-wan-link
  config health-check
    edit <health-check-name>
      set server <server-list>
    next
  end
end

```

where <server-list> is one or more IP addresses or FQDN names of servers.

IPv6 support for SD-WAN

SD-WAN now supports IPv6. It supports all load balance modes, health checking (ping6), and service rules for source address, source user and group, and destination address.

FortiOS 6.0 also increases the configuration limit for health checks and priority rules in SD-WAN. The limit for both health checks and priority rules is increased from 256 to 4096 globally and 512 to 4096 per VDOM.

To configure SD-WAN member interfaces - CLI:

```
config system virtual-wan-link
  config members
    edit <sequence-number>
      set interface <interface-name>
      set {gateway | gateway6} <gateway-address>
    next
  end
end
```

To enable SD-WAN - CLI:

```
config router {static | static6}
  edit <sequence-number>
    set virtual-wan-link enable
  next
end
```

To configure health check (IPv4) - CLI:

```
config system virtual-wan-link
  config health-check
    edit <health-check-name>
      set address-mode ipv4
      set protocol {ping | tcp-echo | udp-echo | http | twamp}
    next
  end
end
```

To configure health check (IPv6) - CLI:

```
config system virtual-wan-link
  config health-check
    edit <health-check-name>
      set address-mode ipv6
      set protocol ping6
    next
  end
end
```

To configure service rules - CLI:

```
config system virtual-wan-link
  config service
    edit <priority-rule-ID>
      set name <rule-name>
```

```

        set addr-mode {ipv4 | ipv6}
        set member <sequence-number>
        set {dst | dst6} <destination-address-name>
        set {src | src6} <source-address-name>
    next
end
end

```

DSCP tagging of forwarded packets in SD-WAN rules

You can now configure DSCP tagging of forwarded packets based on identified applications in SD-WAN rules.

To configure DSCP tagging of forwarded packets in SD-WAN rules - CLI:

```

config system virtual-wan-link
config service
    edit <priority-rule-ID>
        set dscp-forward {enable | disable}
        set dscp-reverse {enable | disable}
        set dscp-forward-tag <binary>
        set dscp-reverse tag <binary> [6 bits binary, range 000000-111111]
    next
end
end

```

where:

- `dscp-forward-tag <binary>` is the forward traffic DSCP tag. It's a 6 bit binary value in the range of 000000-111111.
- `dscp-reverse tag <binary>` is the reverse traffic DSCP tag. It's a 6 bit binary value in the range of 000000-111111.

SD-WAN and dynamic routing

Dynamic routing is now supported for SD-WAN. You can use dynamic routing and SD-WAN. Using BGP, SD-WAN can update its rules using dynamic routes.

To set a route tag in route map rules - CLI:

```

config router route-map
    edit <name>
        config rule
            edit <rule-ID>
                set match-community <BGP-community-list>
                set set-route-tag <route-tag>
            next
        end
    next
end

```

where `<route-tag>` is a number from 0 to 4294967295.

To set health check members - CLI:

```

config system virtual-wan-link
config health-check
    edit <health-check-name>

```

```

        set members <member-sequence-number-list>
    next
end
end

```

To add a route tag in SD-WAN rules - CLI:

```

config system virtual-wan-link
config service
    edit <priority-rule-ID>
        set route-tag <route-map-route-tag>
    next
end
end

```

where <route-tag> is a number from 0 to 4294967295.

Link priority in SD-WAN rules

You can configure the priority for links in SD-WAN rules. You can use the `set mode` command to control how the priority rule sets the priority of interfaces in SD-WAN. If you set this to `priority`, a FortiGate assigns priorities to the interfaces based on the order of the interfaces that you configure using the `set priority-members` command.

In priority mode, when the difference between two links is within the amount that you configure for the `link-cost-threshold`, the FortiGate uses the link with the higher priority, which is the first member in the `priority-members` list.

In SLA mode, the FortiGate assigns the link based on SLA settings.

To set link priority mode in SD-WAN rules - CLI:

```

config system virtual-wan-link
config service
    edit <priority-rule-ID>
        set mode priority
        set link-cost-threshold <threshold-change-percentage>
        set priority-members <member-sequence-list>
    next
end
end

```

SD-WAN rule for address negation

When traffic travels through a FortiGate, it can match a software-defined wide area network (SD-WAN) rule first, even if it's meant for another interface, resulting in a traffic interruption. To avoid this, you can configure an implicit rule for address negation so that SD-WAN policy-based routing (PBR) rules don't match traffic unless the traffic is meant for SD-WAN interfaces.

You can enable address negation for both destination and source address matches. During the process of matching rules, if the rule is an SD-WAN rule, the FortiGate checks the outgoing interface first. If the interface isn't an SD-WAN member interface, the rule is ignored.

To enable the negation of destination address match - CLI:

```

config system virtual-wan-link

```

```
config service
  edit <id>
    set dst-negate enable
  next
end
```

To enable the negation of source address match - CLI:

```
config system virtual-wan-link
  config service
    edit <id>
      set src-negate enable
    next
end
```

SD-WAN CLI changes

The following CLI changes have been made for SD-WAN:

- Removed the timeout option from the link health monitor. You can no longer use the `set timeout` command under the `config system link-monitor` command.
- Removed the timeout option from the health check. You can no longer use the `set timeout` command under the `config health-check` command.

Troubleshooting

Netflow support

Netflow is a networking feature, introduced by Cisco, to collect and export information about traffic flow through routers. IPFIX (Internet Protocol Flow Information Export) is the standardized Internet Protocol based on NetFlow version 9. The standards requirements for IPFIX are outlined in RFC 3197, and its basic specifications and other information are documented in RFC 5103, RFC 6759, and RFC 7011 through RFC 7015.

To enable and configure NetFlow traffic - CLI:

```
config system netflow
  set collector-ip <collector IP>
  set collector-port <NetFlow collector port>
  set csource-ip <Source IP for NetFlow agent>
  set cactive-flow-timeout <time in minutes of timeout to report active flows>
  set cinactive-flow-timeout <time in seconds of timeout for periodic report of finished flows>
end
```

You can also configure these settings per VDOM, using the following CLI command:

```
config system vdom-netflow
```

You must also enable a Netflow sampler on specific interfaces.

sFlow support

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiOS implements sFlow version 5.

sFlow uses packet sampling to monitor network traffic. The sFlow Agent captures packet information at defined intervals and sends them to an sFlow Collector for analysis, providing real-time data analysis. The information sent is only a sampling of the data for minimal impact on network throughput and performance.

The sFlow Agent is embedded in the FortiGate. Once configured, the FortiGate sends sFlow datagrams of the sampled traffic to the sFlow Collector, also called an sFlow Analyzer. The sFlow Collector receives the datagrams, and provides real-time analysis and graphing to indicate where potential traffic issues are occurring. sFlow Collector software is available from a number of third party software vendors.

sFlow data captures only a sampling of network traffic, not all traffic like the traffic logs on the FortiGate. Sampling works by the sFlow Agent looking at traffic packets when they arrive on an interface. A decision is made whether the packet is dropped and allowed to be to its destination or if a copy is forwarded to the sFlow Collector. The sample used and its frequency are determined during configuration.

sFlow is not supported on virtual interfaces such as vdom link, ipsec, ssl.root or gre.

The sFlow datagram sent to the Collector contains the information:

- Packet header (e.g. MAC,IPv4,IPv6,IPX,AppleTalk,TCP,UDP, ICMP)
- Sample process parameters (rate, pool, etc.)
- Input/output ports

- Priority (802.1p and TOS)
- VLAN (802.1Q)
- Source/destination prefix
- Next hop address
- Source AS, Source Peer AS
- Destination AS Path
- Communities, local preference
- User IDs (TACACS/RADIUS) for source/destination
- URL associated with source/destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

sFlow agents can be added to any type of FortiGate interface. sFlow isn't supported on some virtual interfaces such as VDOM link, IPsec, gre, and ssl.root.

For more information on sFlow, Collector software and sFlow MIBs, visit www.sflow.org.

Configuration

sFlow configuration is available only in the CLI. Configuration requires two steps: enabling the sFlow Agent and configuring the interface for the sampling information.

To enable sFlow - CLI:

```
config system sflow
    set collector-ip <ip_address>
    set collector-port <port_number>
    set source-ip <ip_address>
end
```

The default port for sFlow is UDP 6343.

To configure in VDOM - CLI:

```
config system vdom-sflow
    set vdom-sflow enable
    set collector-ip <ip_address>
    set collector-port <port_number>
    set source-ip <ip_address>
end
```

To configure sFlow agents per interface - CLI:

```
config system interface
    edit <interface_name>
        set sflow-sampler enable
        set sample-rate <every_n_packets>
        set sample-direction [tx | rx | both]
        set polling-interval <seconds>
    next
end
```

Packet capture

When troubleshooting networks, it helps to look inside the header of the packets. This helps to determine if the packets, route, and destination are all what you expect. Packet capture can also be called a network tap, packet sniffing, or logic analyzing.

To use the packet capture - GUI:

1. Go to **Network > Packet Capture**.
2. Select **Create New** or select an existing entry if you have already made one that fits your needs.
3. Select the interface to monitor and select the number of packets to keep.
4. Select **Enable Filters**.
5. Enter the information you want to gather from the packet capture.
6. Select **OK**.

To run the capture, select the play button in the progress column in the packet capture list. If it's not active, **Not Running** also appears in the column cell. The progress bar indicates the status of the capture. You can stop and restart it at any time.

When the capture is complete, select the **Download** icon to save the packet capture file to your hard disk for further analysis.

Packet capture tells you what is happening on the network at a low level. This can be very useful for troubleshooting problems, such as:

- Finding missing traffic
- Seeing if sessions are setting up properly
- Locating ARP problems such as broadcast storm sources and causes
- Confirming which address a computer is using on the network if they have multiple addresses or are on multiple networks
- Confirming routing is working as you expect
- Wireless client connection problems
- Intermittent missing PING packets
- A particular type of packet is having problems, such as UDP, which is commonly used for streaming video

If you're running a constant traffic application, such as ping, packet capture can tell you if the traffic is reaching the destination, how the port enters and exits the FortiGate, if the ARP resolution is correct, and if the traffic is returning to the source as expected. You can also use packet switching to verify that NAT, or other configuration, is translating addresses or routing traffic the way that you want it to.

Before you start capturing packets, you need to have a good idea of what you are looking for. Capture is used to confirm or deny your ideas about what is happening on the network. If you try capture without a plan to narrow your search, you can end up with too much data to effectively analyze. On the other hand, you need to capture enough packets to really understand all of the patterns and behavior that you're looking for.

Chapter 18 - Parallel Path Processing (Life of a Packet)

This FortiOS Handbook chapter contains the following sections:

[Parallel Path Processing](#) introduces the concept of Parallel Path Processing.

[Packet flow ingress and egress: FortiGates without network processor offloading](#) describes the overall packet flow through a FortiGate with no network offloading (NP) hardware.

[Packet flow: FortiGates with NP6 processors first packet of a new session](#) similar to the previous section, the first packet in a new session that can be offloaded is processed in much the same way as on a FortiGate with no network processors.

[Packet flow: FortiGates with NP6 processors - packets in an offloaded session](#) describes the much simpler packet flow for a packet from an offloaded session.

[UTM/NGFW packet flow: flow-based inspection](#) describes how single pass UTM/NGFW processing occurs in a flow-based FortiGate or VDOM.

[UTM/NGFW packet flow: proxy-based inspection](#) describes how UTM/NGFW processing occurs in a proxy-based FortiGate or VDOM.

[UTM/NGFW packet flow: explicit web proxy](#) describes how Explicit web proxy processing occurs.

[Comparison of inspection types](#) shows how different security functions map to different inspection types.

Parallel Path Processing

Parallel Path Processing (PPP) uses the firewall policy configuration to choose from a group of parallel options to determine the optimal path for processing a packet. Most FortiOS features are applied through Firewall policies and the features applied determine the path a packet takes. Using firewall policies you can impose UTM/NGFW processing on content traffic that may contain security threats (such as HTTP, email and so on). Many UTM/NGFW processes are offloaded and accelerated by CP8 or CP9 processors. Using the policy configuration you can apply a range of protection from basic IPS attack protection that looks for network-based attacks to full scale advanced threat management (ATM), application control, antivirus, DLP and so on.

You can also create policies for traffic that does not pose security threats and bypass UTM/NGFW checking. This control allows you to improve network performance without compromising security. On FortiGates with network processors (for example the NP6) much of the traffic that does not require UTM/NGFW processing can be offloaded to the NP6 processors freeing up FortiGate processing resources for other higher risk traffic.

In addition, many FortiGate models support NTurbo to offload flow-based UTM/NGFW sessions to network processors. Flow-based sessions can also be accelerated using IPSA technology to enhance offloading of pattern matching to CP8 and CP9 content processors.

This chapter begins with an overview of packet flow ingress and egress and includes a section that shows how NP6 offloading optimizes packet flow for packets that don't require UTM/NGFW processing and for packets that use NTurbo to offload flow-based UTM/NGFW processing.

Next this chapter breaks down how packets pass through UTM/NGFW processing both for a single-pass flow-based UTM/NGFW processing and a proxy-based UTM/NGFW processing.

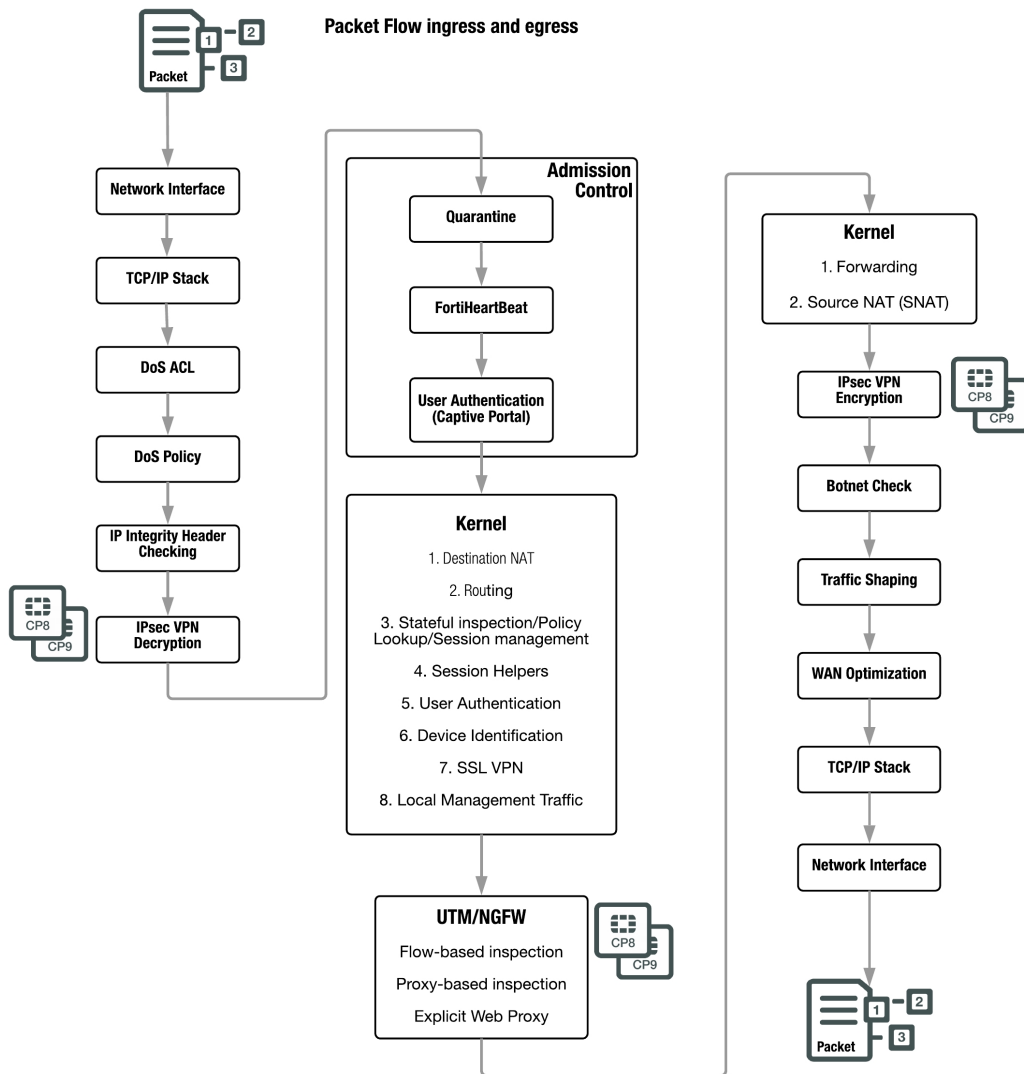

High-level list of processes that affect packets

In general packets passing through a FortiGate can be affected by the following processes. This is a complete high-level list of all of the processes. Not all packets see all of these processes. The processes a packet encounters depends on the type of packet and on the FortiGate software and hardware configuration.

- **Ingress packet flow**
 - Network Interface
 - TCP/IP stack
 - DoS ACL
 - DoS Policy
 - IP integrity header checking
 - IPsec VPN decryption
- **Admission Control**
 - Quarantine
 - FortiTelemetry
 - User Authentication
- **Kernel**
 - Destination NAT
 - Routing
 - Stateful inspection/Policy
Lookup/Session management
 - Session Helpers
 - User Authentication
 - Device Identification
 - SSL VPN
 - Local Management Traffic
- **UTM/NGFW**
 - Flow-based inspection
 - NTurbo
 - IPSA
 - Proxy-based inspection
 - Explicit Web Proxy
- **Kernel**
 - Forwarding
 - Source NAT (SNAT)
- **Egress packet flow**
 - IPsec VPN Encryption
 - Botnet check
 - Traffic shaping
 - WAN Optimization
 - TCP/IP stack
 - Network Interface

Packet flow ingress and egress: FortiGates without network processor offloading

This section describes the steps a packet goes through as it enters, passes through and exits from a FortiGate. This scenario shows all of the steps a packet goes through if a FortiGate does not contain network processors (such as the NP6).

Ingress

All packets accepted by a FortiGate pass through a network interface and are processed by the TCP/IP stack. Then if **DoS policies** or **Access Control List (ACL) policies** have been configured the packet must pass through these as well as automatic **IP integrity header checking**.

DoS scans are handled very early in the life of the packet to determine whether the traffic is valid or is part of a DoS attack. The DoS module inspects all traffic flows but only tracks packets that can be used for DoS attacks (for example, TCP SYN packets), to ensure they are within the permitted parameters. Suspected DoS attacks are blocked, other packets are allowed.

IP integrity header checking reads the packet headers to verify if the packet is a valid TCP, UDP, ICMP, SCTP or GRE packet. The only verification that is done at this step to ensure that the protocol header is the correct length. If it is, the packet is allowed to carry on to the next step. If not, the packet is dropped.

Incoming **IPsec packets** that match configured IPsec tunnels on the FortiGate are decrypted after header checking is done.

If the packet is an IPsec packet, the IPsec engine attempts to decrypt it. If the IPsec engine can apply the correct encryption keys and decrypt the packet, the unencrypted packet is sent to the next step. Non-IPsec traffic and IPsec traffic that cannot be decrypted passes on to the next step without being affected. IPsec VPN decryption is offloaded to and accelerated by CP8 or CP9 processors.

Admission control

Admission control checks to make sure the packet is not from a source or headed to a destination on the quarantine list. If configured admission control then imposes FortiTelemetry protection that requires a device to have FortiClient installed before allowing packets from it. Admission control can also impose captive portal authentication on ingress traffic.

Kernel

Once a packet makes it through all of the ingress steps, the FortiOS kernel performs the following checks to determine what happens to the packet next.

Destination NAT

Destination NAT checks the NAT table and determines if the destination IP address for incoming traffic must be changed using DNAT. DNAT is typically applied to traffic from the internet that is going to be directed to a server on a network behind the FortiGate. DNAT means the actual address of the internal network is hidden from the internet. This step determines whether a route to the destination address actually exists. DNAT must take place before routing so that the FortiGate can route packets to the correct destination.

Routing

Routing uses the routing table to determine the interface to be used by the packet as it leaves the FortiGate. Routing also distinguishes between local traffic and forwarded traffic. Firewall policies are matched with packets depending on the source and destination interface used by the packet. The source interface is known when the packet is received and the destination interface is determined by routing.

Stateful inspection/policy lookup/session management

Stateful inspection looks at the first packet of a session and looks in the policy table to make a security decision about the entire session. Stateful inspection looks at packet TCP SYN and FIN flags to identify the start and end of a session, the source/destination IP, source/destination port and protocol. Other checks are also performed on the packet payload and sequence numbers to verify it as a valid session and that the data is not corrupted or poorly formed.

When the first packet of a session is matched in the policy table, stateful inspection adds information about the session to its session table. So when subsequent packets are received for the same session, stateful inspection can determine how to handle them by looking them up in the session table (which is more efficient than looking them up in the policy table).

Stateful inspection makes the decision to drop or allow a session and apply security features to it based on what is found in the first packet of the session. Then all subsequent packets in the same session are processed in the same way.

When the final packet in the session is processed, the session is removed from the session table. Stateful inspection also has a session idle timeout that removes sessions from the session table that have been idle for the length of the timeout.

See the Stateful Firewall Wikipedia article (https://en.wikipedia.org/wiki/Stateful_firewall) for an excellent description of stateful inspection.

Session helpers

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall. FortiOS includes the following session helpers:

- PPTP
- H323
- RAS
- TNS
- TFTP
- RTSP
- FTP
- MMS
- PMAP
- SIP
- DNS-UDP
- RSH
- DCERPC
- MGCP

User authentication

User authentication added to security policies is handled by the stateful inspection, which is why Firewall authentication is based on IP address. Authentication takes place after policy lookup selects a policy that includes authentication.

Device identification

Device identification is applied if required by the matching policy.

SSL VPN

Local SSL VPN traffic is treated like special management traffic as determined by the SSL VPN destination port. Packets are decrypted and are routed to an SSL VPN interface. Policy lookup is then used to control how packets are forwarded to their destination outside the FortiGate. SSL encryption and decryption is offloaded to and accelerated by CP8 or CP9 processors.

Local management traffic

Local management traffic terminates at a FortiGate interface. This can be any FortiGate interface including dedicated management interfaces. In multiple VDOM mode local management traffic terminates at the management interface. In transparent mode, local management traffic terminates at the management IP address.

Local management traffic includes administrative access, some routing protocol communication, central management from FortiManager, communication with the FortiGuard network and so on. Management traffic is allowed or blocked according to the Local In Policy list which lists all management protocols and their access control settings. You configure local management access indirectly by configuring administrative access and so on.

Management traffic is processed by applications such as the web server which displays the FortiOS GUI, the SSH server for the CLI or the FortiGuard server to handle local FortiGuard database updates or FortiGuard Web Filtering URL lookups.

Local management traffic is not involved in subsequent stateful inspection steps.

SSL VPN traffic terminates at a FortiGate interface similar to local management traffic. However, SSL VPN traffic uses a different destination port number than administrative HTTPS traffic and can thus be detected and handled differently.

UTM/NGFW

If the policy matching the packet includes security profiles, then the packet is subject to Unified Threat Management (UTM)/Next Generation Firewall (NGFW) processing. UTM/NGFW processing depends on the inspection mode of the FortiGate: Flow-based (single pass architecture) or proxy-based. Proxy-based processing can include Explicit web proxy traffic. Many UTM/NGFW processes are offloaded and accelerated by CP8 or CP9 processors.

Single pass flow-based UTM/NGFW inspection identifies and blocks security threats in real time as they are identified using single-pass Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

Proxy-based UTM/NGFW inspection can apply both flow-based and proxy-based inspection. Packets initially encounter the IPS engine, which can apply single-pass flow-based IPS and Application Control (as configured). The packets are then sent to the proxy for proxy-based inspection. Proxy-based inspection can apply VoIP inspection, DLP, AntiSpam, Web Filtering, Antivirus, and ICAP.

Explicit web proxy inspection is similar to proxy based inspection.

Content processors (CP8 and CP9)

Most FortiGate models contain Security Processing Unit (SPU) Content Processors (CPs) that accelerate many common resource intensive security related processes. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 and CP9 processors. Older CP versions still in use in currently operating FortiGate models include the CP4, CP5, and CP6.

CP9 capabilities

The CP9 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration with over 10Gbps throughput
 - IPS pre-scan
 - IPS signature correlation
 - Full match processors
- High performance VPN bulk data engine
 - IPsec and SSL/TLS protocol processor
 - DES/3DES/AES128/192/256 in accordance with FIPS46-3/FIPS81/FIPS197
 - MD5/SHA-1/SHA256/384/512-96/128/192/256 with RFC1321 and FIPS180
 - HMAC in accordance with RFC2104/2403/2404 and FIPS198
 - ESN mode
 - GCM support for NSA "Suite B" (RFC6379/RFC6460) including GCM-128/256; GMAC-128/256
- Key Exchange Processor that supports high performance IKE and RSA computation
 - Public key exponentiation engine with hardware CRT support
 - Primary checking for RSA key generation
 - Handshake accelerator with automatic key material generation
 - True Random Number generator
 - Elliptic Curve support for NSA "Suite B"
 - Sub public key engine (PKCE) to support up to 4096 bit operation directly (4k for DH and 8k for RSA with CRT)
- DLP fingerprint support
 - TTTD (Two-Thresholds-Two-Divisors) content chunking
 - Two thresholds and two divisors are configurable

CP8 capabilities

The CP8 content processor provides the following services:

- Flow-based inspection (IPS, application control etc.) pattern matching acceleration
- High performance VPN bulk data engine
 - IPsec and SSL/TLS protocol processor
 - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
 - ARC4 in compliance with RC4
 - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
 - HMAC in accordance with RFC2104/2403/2404 and FIPS198
- Key Exchange Processor support high performance IKE and RSA computation
 - Public key exponentiation engine with hardware CRT support
 - Primarily checking for RSA key generation
 - Handshake accelerator with automatic key material generation
 - Random Number generator compliance with ANSI X9.31
 - Sub public key engine (PKCE) to support up to 4096 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by many applications)
- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

Kernel

Traffic is now in the process of exiting the FortiGate. The kernel uses the routing table to forward the packet out the correct exit interface.

The kernel also checks the NAT table and determines if the source IP address for outgoing traffic must be changed using SNAT. SNAT is typically applied to traffic from an internal network heading out to the internet. SNAT means the actual address of the internal network is hidden from the internet.

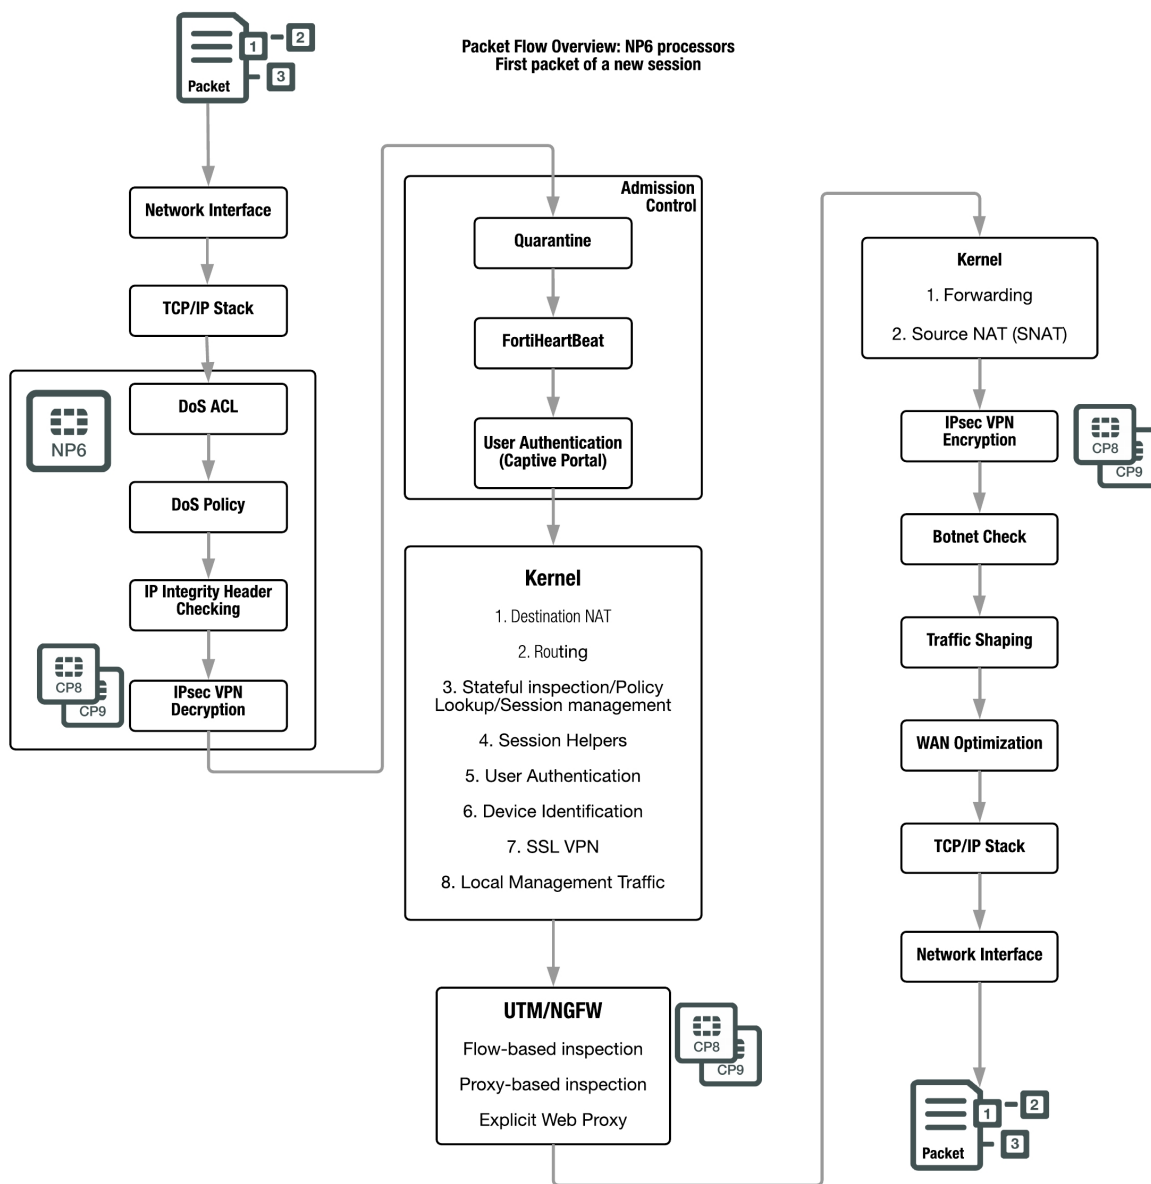

Egress

Before exiting the FortiGate, outgoing packets that are entering an IPsec VPN tunnel are encrypted and encapsulated. IPsec VPN encryption is offloaded to and accelerated by CP8 or CP9 processors. Packets are then subject to botnet checking to make sure they are not destined for known botnet addresses.

Traffic shaping is then imposed, if configured, followed by WAN Optimization. The packet is then processed by the TCP/IP stack and exits out the egress interface.

Packet flow: FortiGates with NP6 processors first packet of a new session

On a FortiGate with NP6 processors the first packet in a new session is handled the same way as on a FortiGate with no NP6 processors. Except that some processes, such as DoS, ACL, IP integrity checking, and IPsec VPN decryption are accelerated by the NP6 processor.

Network processors (NP6)

NP6 and NP6lite network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP6 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP6 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP6 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP6 processor plus the network processing load is removed from the CPU. In addition the NP6 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

NP6lite processors have the same architecture and function in the same way as NP6 processors. All of the descriptions of NP6 processors in this document can be applied to NP6lite processors except where noted.

Session keys (and IPsec SA keys) are stored in the memory of the NP6 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP6. There is no dependence on getting the right pair of interfaces since the offloading is done by the receiving NP6.

The key to making this possible is an Integrated Switch Fabric (ISF) that connects the NP6s and the FortiGate unit interfaces together. Many FortiGate units with NP6 processors also have an ISF. The ISF allows any port connectivity. All ports and NP6s can communicate with each other over the ISF. There are no special ingress and egress fast path requirements as long as traffic enters and exits on interfaces connected to the same ISF.

Some FortiGate units, such as the FortiGate-1000D include multiple NP6 processors that are not connected by an ISF. Because the ISF is not present fast path acceleration is supported only between interfaces connected to the same NP6 processor. Since the ISF introduces some latency, models with no ISF provide low-latency network acceleration between network interfaces connected to the same NP6 processor.

Each NP6 has a maximum throughput of 40 Gbps using 4 x 10 Gbps XAUI or Quad Serial Gigabit Media Independent Interface (QSGMII) interfaces or 3 x 10 Gbps and 16 x 1 Gbps XAUI or QSGMII interfaces.

There are at least two limitations to keep in mind:

- The capacity of each NP6 processor. An individual NP6 processor can support between 10 and 16 million sessions. This number is limited by the amount of memory the processor has. Once an NP6 processor hits its session limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP6 processors. To be able to do this you need to be aware of which interfaces connect to which NP6 processors and distribute incoming traffic accordingly.
- The NP6 processors in some FortiGate units employ NP direct technology that removes the ISF. The result is very low latency but no inter-processor connectivity requiring you to make sure that traffic to be offloaded enters and exits the FortiGate through interfaces connected to the same NP processor.

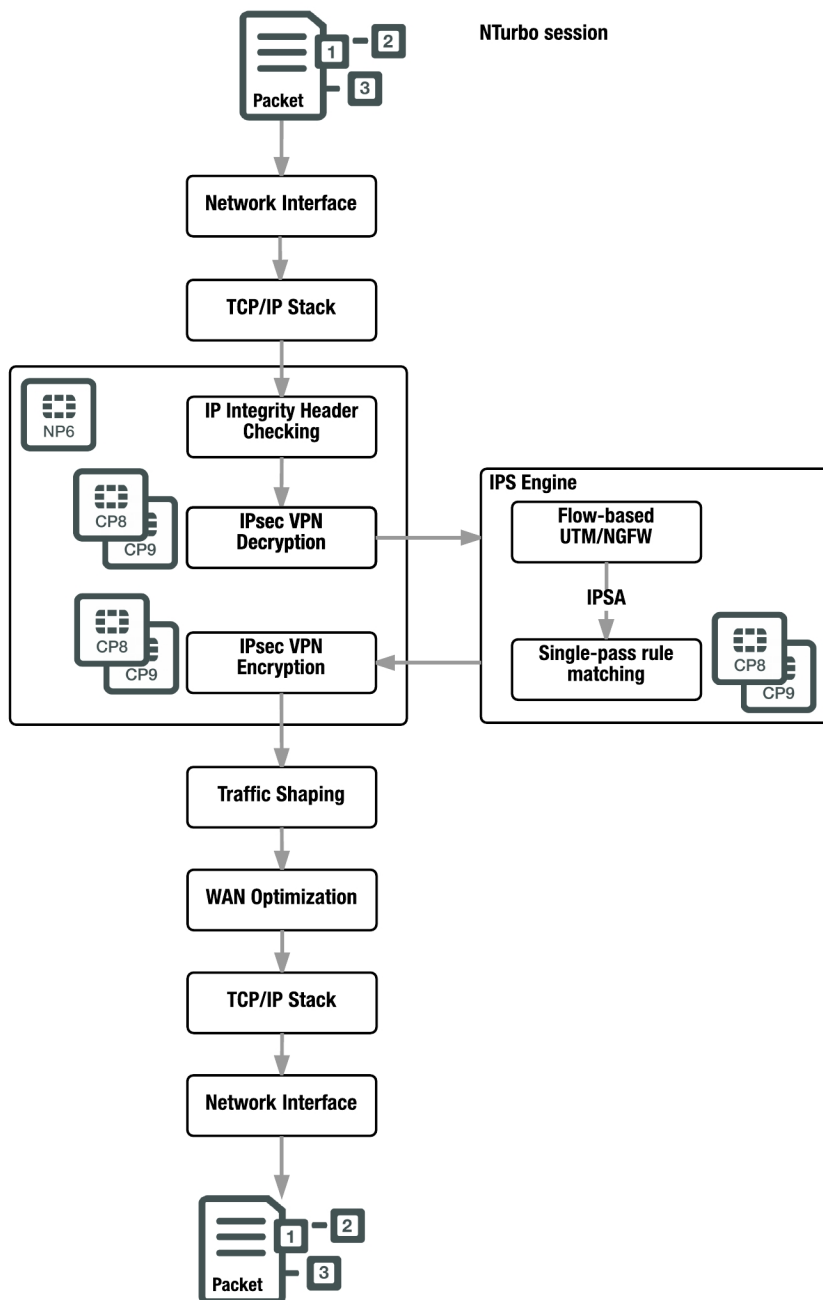

Packet flow: FortiGates with NP6 processors - packets in an offloaded session

The first packet of a session determines if the session can be offloaded. As long as there is no proxy-based UTM/NGFW, if your FortiGate includes NP6 processors, most sessions can be offloaded to them. After the first packet, subsequent packets in an offloaded session skip routing, UTM/NGFW, and kernel processors and are just forwarded out the egress interface by the NP6 processor. As well, security measures such as DoS policies, ACL, and so on are accelerated by the NP6 processor.

Packet flow: FortiGates with NP6 processors - packets in an NTurbo session

If your FortiGate supports NTurbo, many flow-based UTM/NGFW sessions can be offloaded to NP6 processors.

After the first packet, subsequent packets in an offloaded flow-based UTM/NGFW session skip routing, and kernel processors. Flow-based UTM/NGFW operations are still handled by the CPU with IPSA offloading pattern matching to CP8 or CP9 processors.

If a security threat is found the session is dropped. Otherwise, packets that are not blocked by UTM/NGFW are forwarded out of the egress interfaces by the NP6 processor.

NTurbo is not compatible with DoS policies, session helpers, or and most types of tunneling. If any of these features are present, flow-based UTM/NGFW sessions are not offloaded by NTurbo.

UTM/NGFW packet flow: flow-based inspection

Flow-based UTM/NGFW inspection identifies and blocks security threats in real time as they are identified using single-pass architecture that involves Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

If a FortiGate or a VDOM is configured for flow-based inspection, depending on the options selected in the firewall policy that accepted the session, flow-based inspection can apply **IPS**, **Application Control**, **Web Filtering**, **DLP**, and **AntiVirus**. Flow-based inspection is all done by the IPS engine and as you would expect, no proxying is involved.

Flow-based DLP is supported but not recommended. Flow-based DLP is not available from the GUI, but can be configured from the CLI.

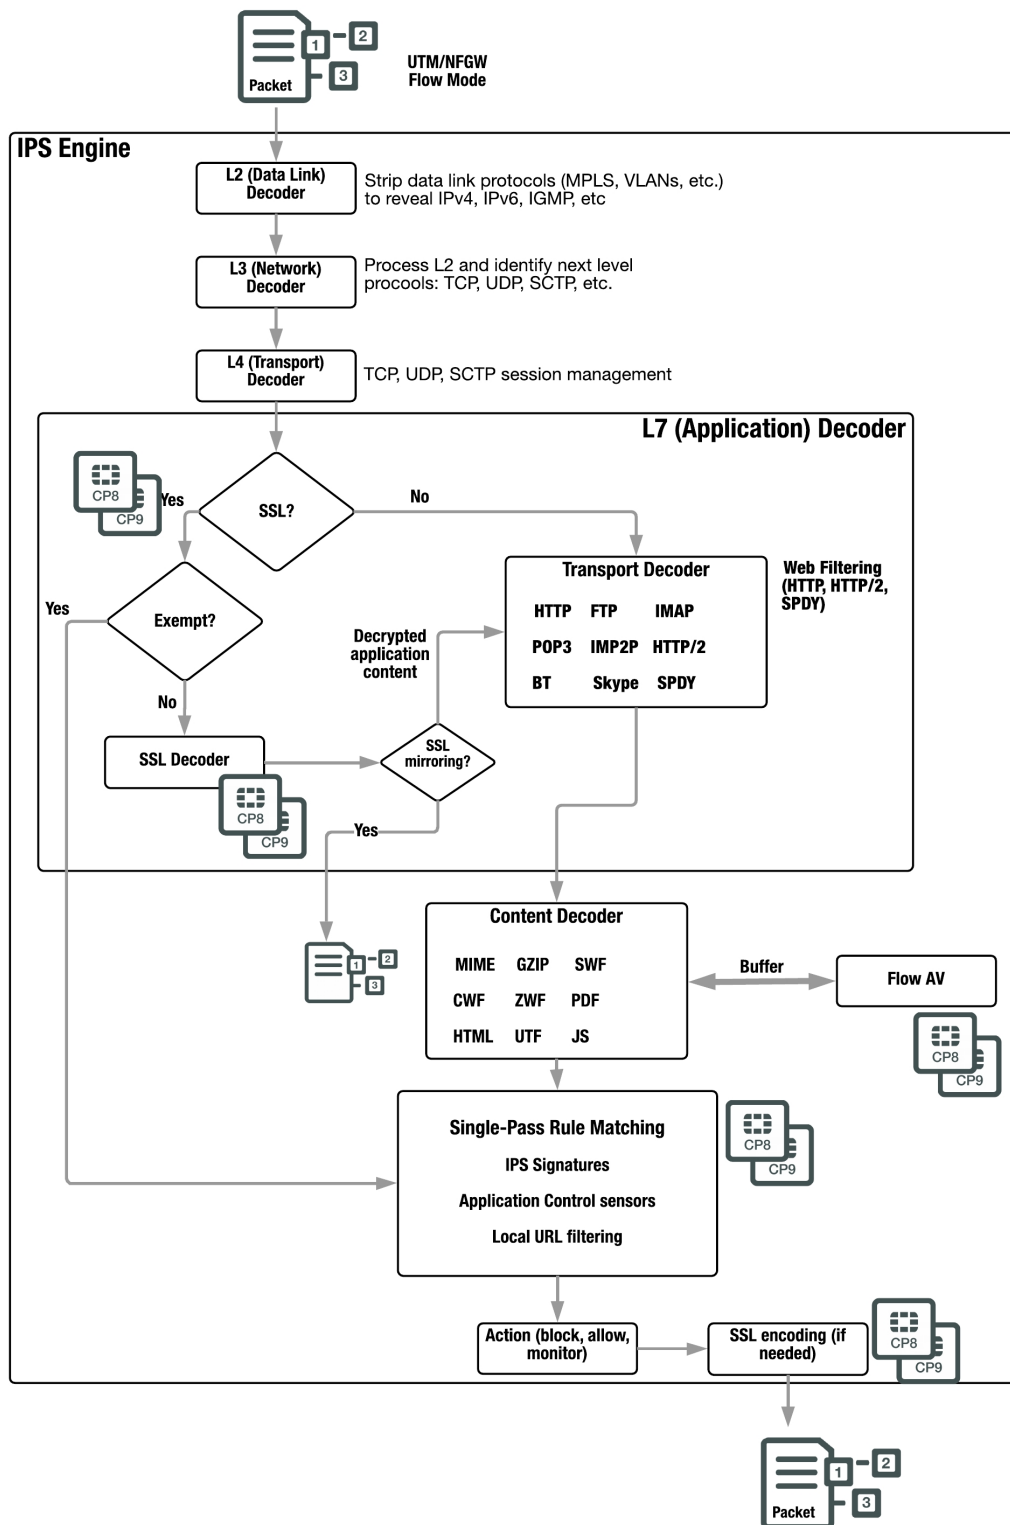

Before flow-based inspection can be applied the IPS engine uses a series of decoders to determine the appropriate security modules to be applied depending on the protocol of the packet and on policy settings. In addition, if SSL inspection is configured, the IPS engine also decrypts SSL packets. SSL decryption is offloaded and accelerated by CP8 or CP9 processors.

If your configuration includes SSL mirroring, the IPS engine copies decrypted application content, wraps it inside a TCP packet (with IP and ethernet headers), and sends it to the configured mirror interface. The TCP connection tuple is carried over from the original SSL connection. For the Ethernet frame, destination address is broadcast (FF:FF:FF:FF:FF:FF) and source address is all zeros.

All of the applicable flow-based security modules are applied simultaneously in one single pass, and pattern matching is offloaded and accelerated by CP8 or CP9 processors. IPS, Application Control, flow-based Web Filtering and flow-based DLP filtering happen together. Flow-based antivirus caches files during protocol decoding and submits cached files for virus scanning while the other matching is carried out.

Flow-based inspection typically requires less processing resources than proxy-based inspection and since its not a proxy, flow-based inspection does not change packets (unless a threat is found and packets are blocked). Flow-based inspection cannot apply as many features as proxy inspection (for example, flow-based inspection does not support client comforting and some aspects of replacement messages).

IPS and Application Control are only applied using flow-based inspection. Web Filtering, DLP and Antivirus can also be applied using proxy-based inspection.

UTM/NGFW packet flow: proxy-based inspection

If a FortiGate or VDOM is configured for proxy-based inspection then a mixture of flow-based and proxy-based inspection occurs. Packets initially encounter the IPS engine, which uses the same steps described in [UTM/NGFW packet flow: flow-based inspection on page 2298](#) to apply single-pass IPS and Application Control if configured in the firewall policy accepting the traffic.

The packets are then sent to the FortiOS UTM/NGFW proxy for proxy-based inspection. The proxy first determines if the traffic is SSL traffic that should be decrypted for SSL inspection. SSL traffic to be inspected is decrypted by the proxy. SSL decryption is offloaded to and accelerated by CP8 or CP9 processors.

If your configuration includes SSL mirroring, the IPS engine copies decrypted application content, wraps it inside a TCP packet (with IP and ethernet headers), and sends it to the configured mirror interface. The TCP connection tuple is carried over from the original SSL connection. For the Ethernet frame, destination address is broadcast (FF:FF:FF:FF:FF:FF) and source address is all zeros.

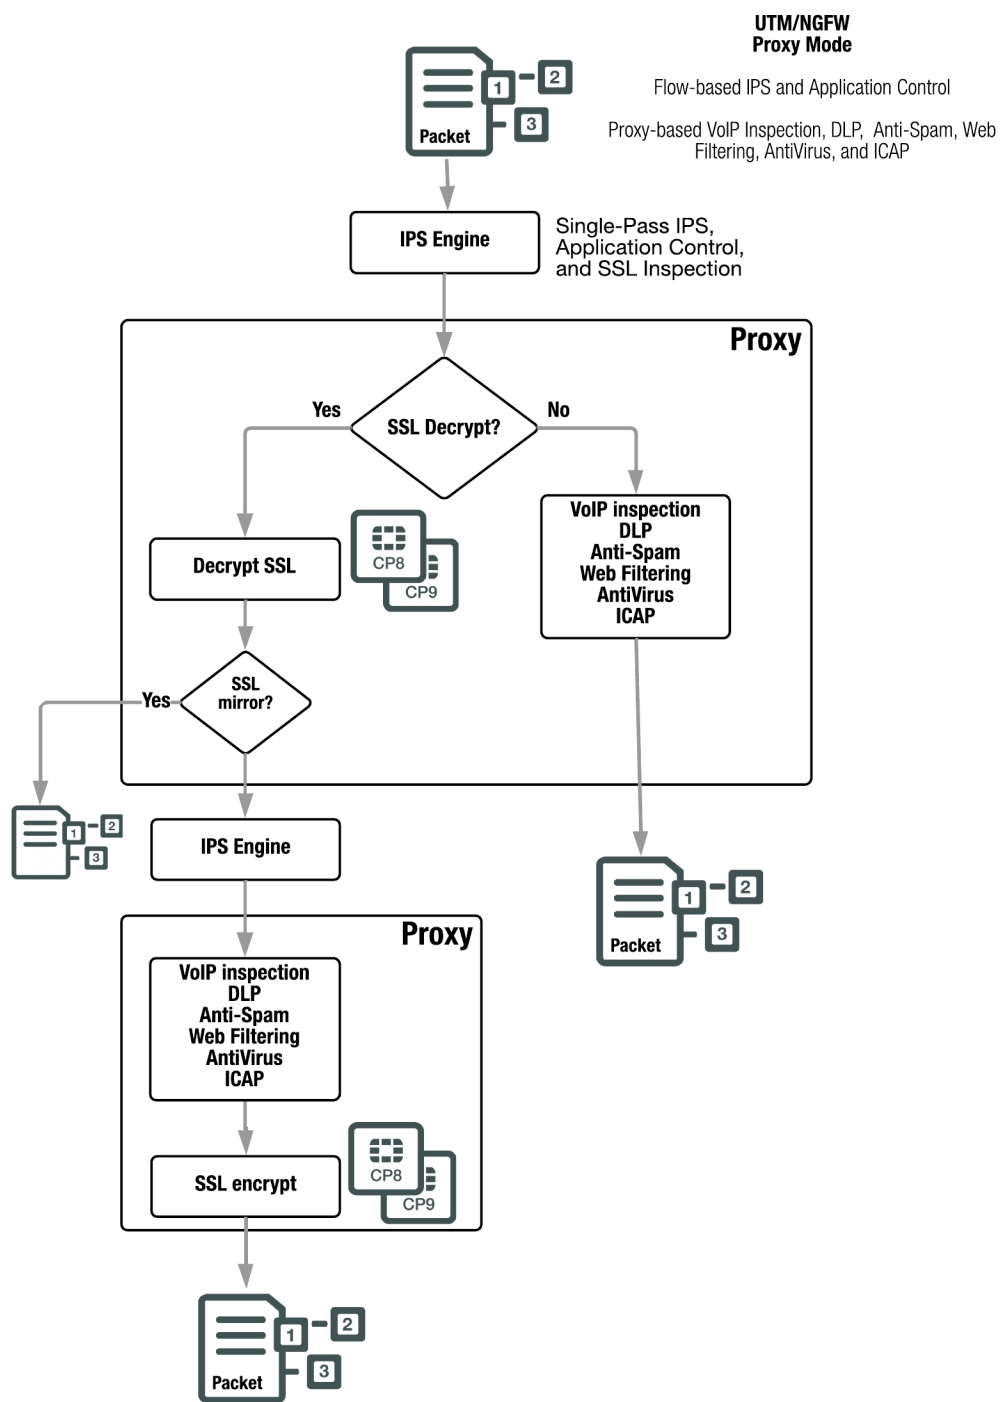

Proxy-based inspection extracts and caches content, such as files and web pages, from content sessions and inspects the cached content for threats. Content inspection happens in the following order: **VoIP inspection**, **DLP**, **Ant-Spam**, **Web Filtering**, **AntiVirus**, and **ICAP**.

If no threat is found the proxy relays the content to its destination. If a threat is found the proxy can block the threat and replace it with a replacement message.

Decrypted SSL traffic is sent to the IPS engine (where IPS and Application Control can be applied) before re-entering the proxy where actual proxy-based inspection is applied to the decrypted SSL traffic. Once decrypted SSL traffic has been inspected it is re-encrypted and forwarded to its destination. SSL encryption is offloaded to and accelerated by CP8 or CP9 processors. If a threat is found the proxy can block the threat and replace it with a replacement message.

The proxy can also block VoIP traffic that contains threats. VoIP inspection can also look inside VoIP packets and extract port and address information and open pinholes in the firewall to allow VoIP traffic through.

ICAP intercepts HTTP and HTTPS traffic and forwards it to an ICAP server. The FortiGate is the surrogate, or “middle-man”, and carries the ICAP responses from the ICAP server to the ICAP client; the ICAP client then responds back, and the FortiGate determines the action that should be taken with these ICAP responses and requests.

UTM/NGFW packet flow: explicit web proxy

If the explicit web proxy is enabled on a FortiGate or VDOM, a mixture of flow-based and proxy-based inspection occurs. One or more interfaces configured to listen for web browser sessions on the configured explicit web proxy port (by default 8080) accept all HTTP and HTTPS sessions on the explicit proxy port that match an explicit web proxy policy.

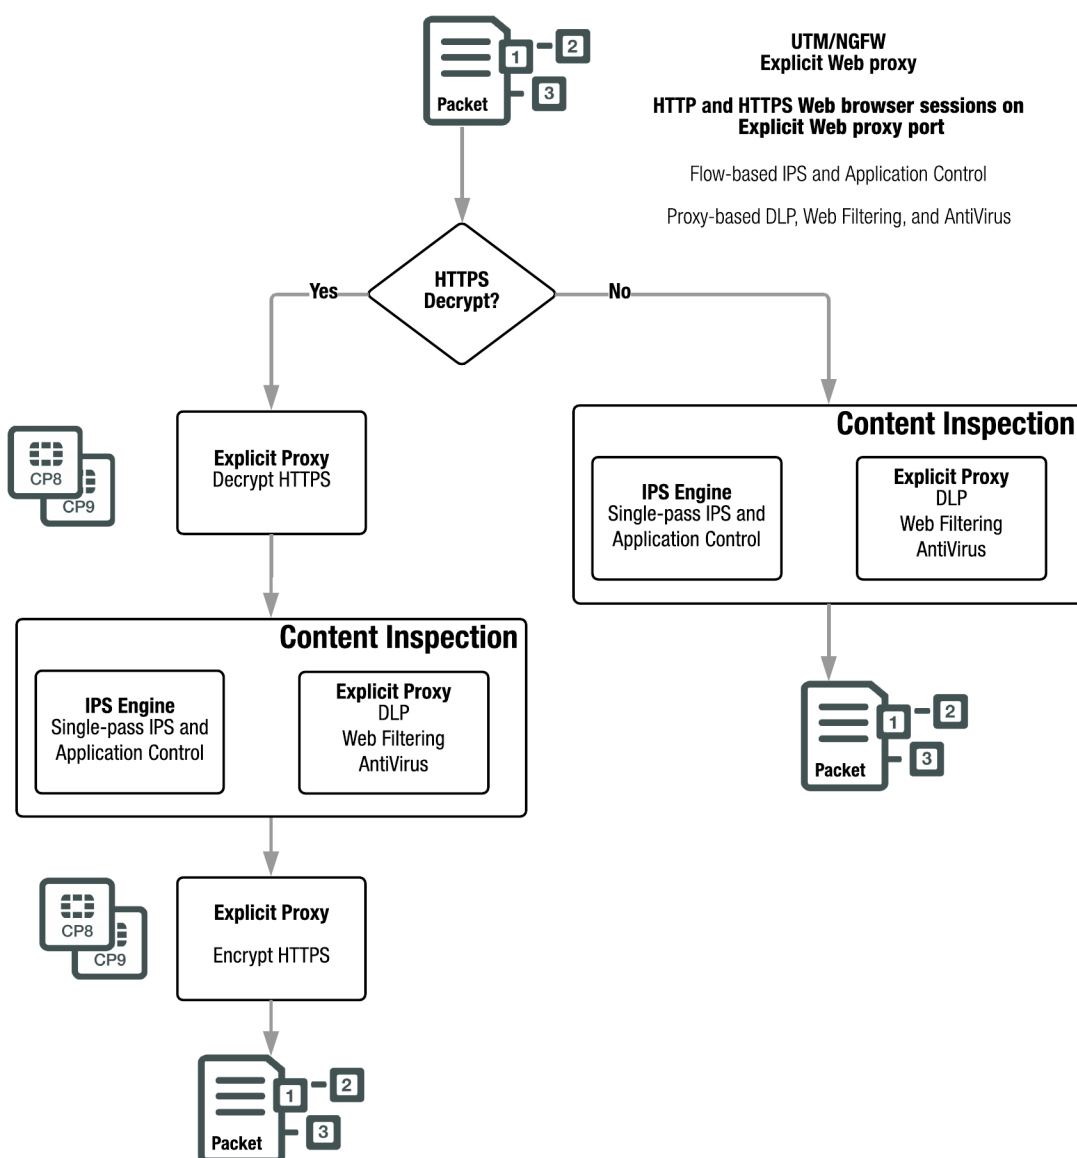

Plain text explicit web proxy HTTP traffic passes in parallel to both the IPS engine and the explicit web proxy for content scanning. The IPS engine applies IPS and application control content scanning. The explicit web proxy applies DLP, web filtering, and AntiVirus content scanning.

If the IPS engine and the explicit proxy do not detect any security threats, FortiOS relays the content to a destination interface. If the IPS engine or the explicit proxy detect a threat, FortiOS can block the threat and replace it with a replacement message.

Encrypted explicit web proxy HTTPS traffic passes to the explicit web proxy for decryption. Decrypted traffic once again passes in parallel to the IPS engine and the explicit web proxy for content scanning.

If the IPS engine and the explicit proxy do not detect any security threats, the explicit proxy re-encrypts the traffic and FortiOS relays the content to its destination. If the IPS engine or the explicit proxy detect a threat, FortiOS can block the threat and replace it with a replacement message. The explicit proxy offloads HTTPS decryption and encryption to CP8 or CP9 processors.

FortiOS uses routing to route explicit web proxy sessions through the FortiGate to a destination interface. Before a session leaves the exiting interface, the explicit web proxy changes the source addresses of the session packets to the IP address of the exiting interface. A FortiGate operating in transparent mode changes the source address to the transparent mode management IP address. You can also configure the explicit web proxy to keep the original client IP address.

Comparison of inspection types

The tables in this section show how different security functions map to different inspection types.

Mapping security functions to inspection types

The table below lists FortiOS security functions and shows whether they are applied by the kernel, flow-based inspection or proxy-based inspection.

FortiOS security functions and inspection types

Security Function	Kernel (Stateful inspection)	Flow-based inspection	Proxy-based inspection
Firewall	yes		
IPsec VPN	yes		
Traffic Shaping	yes		
User Authentication	yes		
Management Traffic	yes		
SSL VPN	yes		
IPS		yes	
Antivirus		yes	yes
Application Control		yes	
Web filtering		yes	yes
DLP		yes	yes
Email Filtering			yes
VoIP inspection			yes
ICAP			yes

More information about inspection methods

The three inspection methods each have their own strengths and weaknesses. The following table looks at all three methods side-by-side.

Inspection methods comparison

Feature	Stateful	Flow	Proxy
Inspection unit per session	first packet	selected packets, single pass architecture, simultaneous application of configured inspection methods	complete content, configured inspection methods applied in order
Memory, CPU required	low	medium	high
Level of threat protection	good	better	best
Authentication	yes		
IPsec and SSL VPN	yes		
Antivirus protection		yes	yes
Web Filtering		yes	yes
Data Leak Protection (DLP)		yes	yes
Application control		yes	
IPS		yes	
Delay in traffic	minor	no	small
Reconstruct entire content		no	yes

Chapter 19 - Sandbox Inspection

This guide explains how to set up sandbox inspection using FortiSandbox with a FortiGate. It contains the following sections:

- [An Overview of Sandbox Inspection](#): General information about how sandbox inspection works.
- [Using FortiSandbox with a FortiGate](#): How to set up sandbox inspection on a FortiGate.
- [Sandbox Integration](#): Integrating sandbox inspection with FortiGate, FortiSandbox, and FortiClient.
- [Sandbox Inspection FAQ](#): Frequently asked questions to help troubleshoot sandbox inspection.

An Overview of Sandbox Inspection

This section contains information about how Fortinet sandbox inspection works.

- [What is Sandbox Inspection?](#)
- [FortiSandbox Appliance vs FortiSandbox Cloud](#)
- [Sending Files for Sandbox Inspection](#)

What is Sandbox Inspection?

Sandbox inspection is a network process that allows files to be sent to a separate device, such as FortiSandbox, to be inspected without risking network security. This allows the detection of threats which may bypass other security measures, including zero-day threats.

You can configure your FortiGate device to send suspicious files to FortiSandbox for inspection and analysis. The FortiGate queries scan results and retrieves scan details. The FortiGate can also download malware packages as a complimentary AV signature database to block future appearances of the same malware and download URL packages as complimentary web filtering black list.

When a FortiGate sends files for sandbox inspection, the FortiSandbox uses virtual machines (VMs) running different operating systems to test the file and to determine if it is malicious. If the file exhibits risky behavior, or is found to contain a virus, a new signature can be added to the FortiGuard AntiVirus signature database.

When a FortiGate learns from FortiSandbox that a terminal is infected, the administrator can push instruction for self-quarantine on a registered FortiClient host.

FortiSandbox can process multiple files simultaneously since the FortiSandbox has a VM pool. The time to process a file depends on hardware and the number of sandbox VMs used to scan the file. It can take 60 seconds to five minutes to process a file.

FortiSandbox Appliance vs FortiSandbox Cloud

FortiSandbox is available as a physical or virtual appliance (FortiSandbox Appliance), or as a cloud advanced threat protection service integrated with FortiGate (FortiSandbox Cloud).

To select the settings for **Sandbox Inspection**, such as the FortiSandbox type, server, and notifier email, go to **Security Fabric > Settings**.

The table below highlights the supported features of both types of FortiSandbox:

Feature	FortiSandbox Appliance (including VM)	FortiSandbox Cloud
Sandbox inspection for FortiGate	Yes (FortiOS 5.0.4+)	Yes (FortiOS 5.2.3+)
Sandbox inspection for FortiMail	Yes (FortiMail OS 5.1+)	Yes (FortiMail OS 5.3+)
Sandbox inspection for FortiWeb	Yes (FortiWeb OS 5.4+)	Yes (FortiWeb OS 5.5.3+)
Sandbox inspection for FortiClient	Yes (FortiClient 5.4+ for Windows only)	No
Sandbox inspection for network share	Yes	No
Sandbox inspection for ICAP client	Yes	No
Manual File upload for analysis	Yes	Yes
Sniffer mode	Yes	Yes
File Status Feedback and Report	Yes	Yes
Dynamic Threat Database updates for FortiGate	Yes (FortiOS 5.4+)	Yes (FortiOS 5.4+)
Dynamic Threat Database updates for FortiClient	Yes (FortiClient 5.4 for Windows only)	Yes (FortiClient 5.6+ for Windows only)

Note that FortiMail keeps its own Dynamic Threat Database. For more information, see the [FortiSandbox documentation](#).

Sending Files for Sandbox Inspection

Sending files to the FortiSandbox appliance or to FortiSandbox Cloud does not block files immediately. Instead, the files assist in the discovery of new threats and the creation of new signatures to be added to the global FortiGuard AntiVirus database. Files deemed malicious are also immediately added to a custom Malware Package which is downloaded by the FortiGate every two minutes for live detection.

Enable **Sandbox Inspection** by going to **Security Fabric > Settings**. You can also configure the FortiSandbox type, server, and notifier email.

To see options for sending files for sandbox inspection, go to **Security Profiles > AntiVirus**. There are two options for sending files: **None** or **All Supported Files**. If **All Supported Files** is selected, users can withhold files from being submitted for inspection by type or name pattern.

To learn how to connect the FortiSandbox, go to ["Using FortiSandbox with a FortiGate" on page 2309](#)

Using FortiSandbox with a FortiGate

This section contains information about how to use sandbox inspection with FortiSandbox and FortiGate. It includes the following sections:

- [Connecting a FortiGate to FortiSandbox](#)
- [FortiSandbox Console](#)

Connecting a FortiGate to FortiSandbox

The procedures for connecting a FortiGate to FortiSandbox differ depending whether you are using [FortiSandbox Appliance](#) or [FortiSandbox Cloud](#).

If you are using FortiSandbox in a Fortinet Security Fabric, consult the [Fortinet Cookbook](#) site for the [Fortinet Security Fabric collection](#) of recipes.

Once the FortiGate is connected to FortiSandbox, an AntiVirus profile can be configured to send suspicious files for inspection. Sandbox integration can also be configured, for more information see "[Sandbox Integration](#)" on [page 2311](#).

Connecting to FortiSandbox Appliance

1. Connect the FortiSandbox Appliance to your FortiGate so that port 1 and port 3 on the FortiSandbox are on different subnets.

FortiSandbox port 3 is used for outgoing communication triggered by the execution of the files under analysis. While the FortiSandbox can accept files through any port, it is recommended to connect port 3 to a dedicated interface on your FortiGate to protect the rest of the network from threats currently being investigated by the FortiSandbox. Note too that port 1 can be used to accept files but is generally reserved for managing the FortiSandbox.

2. FortiSandbox port 3 must be able to connect to the Internet. On the FortiGate, go to **Policy & Objects > IPv4 Policy** and create a policy allowing connections from the FortiSandbox to the Internet (using the isolated interface on the FortiGate mentioned above). On FortiSandbox, network settings for port3 can be configured by going to **Scan Policy > General**.
3. On the FortiSandbox, go to **Network > System Routing** and add static routes for port 1.
4. On the FortiSandbox, go to **Dashboard** and locate the **System Information** widget. Now that the FortiSandbox has Internet access, it can activate its VM licenses. Wait until a green arrow shows up beside **Windows VM** before continuing to the next step.
5. On the FortiGate, go to **Security Fabric > Settings**. Select **Enable Sandbox Inspection** and select **FortiSandbox Appliance**. Set the **IP Address** and enter a **Notifier Email**. If you select **Test Connectivity**, the **Status** shows as **Service is not configured** because the FortiGate has not been authorized to connect to the FortiSandbox.
6. On the FortiSandbox, go to **Scan Input > Device**. **Edit** the entry for the FortiGate. Under **Permissions & Policy > Authorized**, select the checkbox and click **OK** to authorize the FortiGate.

- On the FortiGate, go to **Security Fabric > Settings** and select **Test Connectivity** for the FortiSandbox. The **Status** now shows that **Service is online**.

Connecting to FortiSandbox Cloud

Before you can connect a FortiGate to FortiSandbox Cloud, you need an active FortiCloud account. For more information, see the [FortiCloud documentation](#).

Once you have created a FortiCloud account, sandbox inspection should be enabled by default. To verify this, go to **Security Fabric > Settings**, enable **Sandbox Inspection**, and set to **FortiSandbox Cloud**.

To see the results from FortiSandbox Cloud in the FortiGate logs, go to **Log & Report > Log Settings** and enable **Send Logs to FortiCloud** and set **GUI Preferences** is to display logs from FortiCloud.

FortiSandbox Console

The FortiSandbox console is available at **FortiView > FortiSandbox**. The console displays all samples submitted for inspection. Information on the console can be filtered by checksum, file name, result, source, status, and user name.

Add Filter		Files	Source	5 minutes	1 hour	24 hours
Source	File Name	Status	Submitted			
vickimartin (192.168.200.110)	Breakpoints.js	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	Corp_Reverb.css	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	FortiOS%205.2%20CLI_sx.js	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	Language.js	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	MadCapAll.js	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	Slideshow.css	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	Toc.js	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	Toc_Chunk6.js	Clean	10/02/2015 09:40:00			
vickimartin (192.168.200.110)	Web.css	Clean	10/02/2015 09:40:00			

If you right-click on an entry, you can choose to **Drill Down to Details**, **Quarantine Source Address**, or **Quarantine FortiClient Device**.

Information about the FortiSandbox database and sandboxing statistics are available at **Security Fabric > Settings** once sandbox inspection is enabled. The **Advanced Threat Protection** dashboard widget shows you the number of files that your FortiGate unit has uploaded or submitted to FortiSandbox.

Refer to [FortiSandbox documentation](#) for details on what you can access through the FortiSandbox GUI .

Sandbox Integration

Sandbox integration adds another level to sandbox inspection, allowing you to set up automatic actions to protect your network from files FortiSandbox determines are malicious. These actions include: receiving AntiVirus signature updates from FortiSandbox, adding the originating URL of any malicious file to a blocked URL list, and extending sandbox scanning to FortiClient devices.

This section contains the following topics:

- [Overview](#)
- [Example Configuration](#)

Overview

FortiSandbox integration involves three different FortiGate security profiles: [AntiVirus](#), [Web Filtering](#), and [FortiClient Profiles](#).

A FortiGate can retrieve scan results and details from FortiSandbox, and also receive antivirus and web filtering signatures to supplement the current signature database. When FortiGate learns from FortiSandbox that an endpoint is infected, the administrator can push instruction for self-quarantine on a registered FortiClient host.

When integrated with a FortiGate unit, the following protocols are supported by FortiSandbox: HTTP, HTTPS, FTP, FTPS, POP3, POP3S, IMAP, IMAPS, SMTPS, MAPI, MAPIS, SMB, and supported IM protocols.

AntiVirus

When FortiSandbox discovers a malicious file, it can create an AntiVirus signature for that file and add that signature to both the local FortiGate malware database and the FortiGuard AntiVirus signature database. Through FortiSandbox integration, this signature can be sent to a FortiGate to block the file from re-entering the network and to prevent the future retransmission of that file to FortiSandbox.

Use of the FortiSandbox AntiVirus database is enabled in an AntiVirus profile, found at **Security Profiles > AntiVirus**. It can also be configured using the following CLI commands:

```
config antivirus profile
  edit <profile>
    set analytics-db enable
  end
```

Web Filtering

FortiSandbox integration can also be used to allow FortiSandbox to add a URL filter blocking the source of a discovered malicious file to the FortiGate's blocked URL list.

Blocking malicious URLs discovered by FortiSandbox is enabled in a Web Filter profile, found at **Security Profiles > Web Filter**. It can also be configured using the following CLI commands:

```
config webfilter profile
  edit <profile>
    config web
      set blacklist enable
    end
```

FortiClient Profiles

Extended FortiSandbox scanning is currently only supported by FortiClient 5.4 for Windows. It can also only be used with FortiSandbox Appliance.

When extended FortiSandbox scanning is enabled for FortiClient, files downloaded by FortiClient can be sent to the FortiSandbox for inspection. Also, if a suspicious file is discovered, FortiClient can be configured to wait until sandbox inspection is complete before allowing that file to be accessed.

AntiVirus signatures can also be pushed by the FortiGate to FortiClient.

If a FortiClient device attempts to download a file that FortiSandbox discovers is malicious, the FortiSandbox notifies the FortiGate. The administrator can take action to quarantine the device. When a quarantine is in effect, FortiClient cuts off other network traffic from the device directly, preventing it from infecting or scanning the local network. When a device is under quarantine, FortiClient cannot be shutdown or uninstalled. A user is also unable to unregister from the FortiGate that quarantined them, or register to another FortiGate unit. A quarantine can only be lifted by the administrator of the FortiGate where the FortiClient device is registered.

Extending FortiSandbox scanning can be configured in the **Security** settings of a FortiClient Profile, found at **Security Profiles > FortiClient Compliance**. It can also be configured using the following CLI commands:

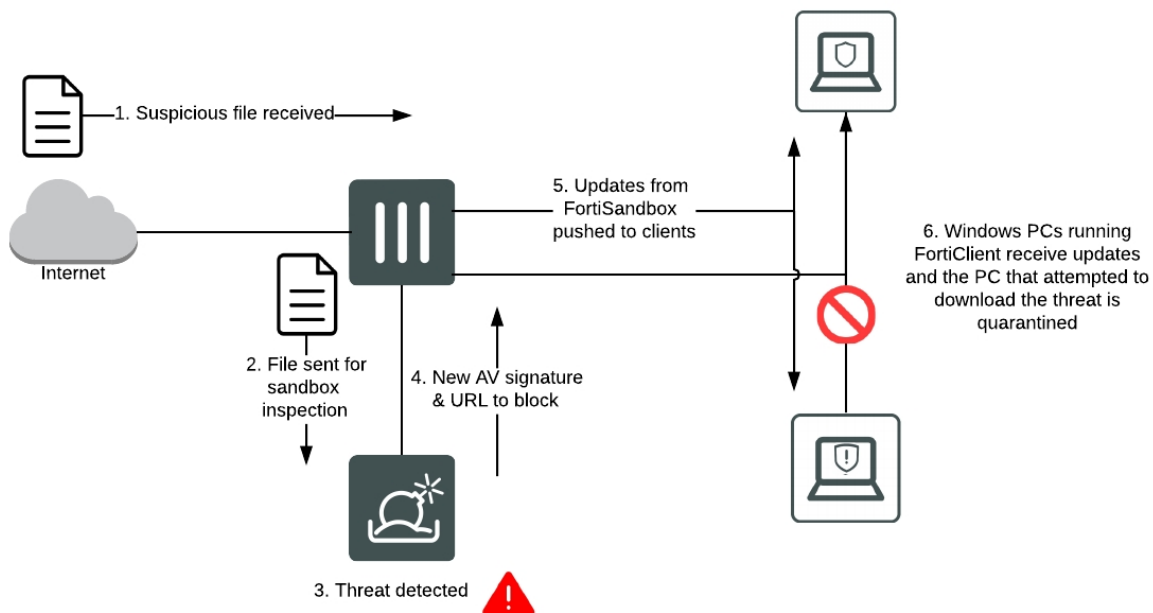

```
config endpoint-control profile
edit <profile>
config forticlient-winmac-settings
set forticlient-av enable
set av-realtime-protection enable
set sandbox-analysis enable
set sandbox-address <address>
end
```

Extending FortiSandbox scanning can also be configured directly in the FortiClient **AntiVirus** settings. If you are using FortiClient version 5.6+, the **Sandbox Detection** feature can be used to send files to FortiSandbox for analysis without having to install the AntiVirus feature. See the FortiClient 5.6 Administration Guide for details.

The number of files sent from a single device to FortiSandbox can be limited by [configuring the submission limit](#) on the FortiSandbox. This allows users to prioritize which devices get the greater share of FortiSandbox resources.

Example Configuration

The following example configuration sets up FortiSandbox integration using AntiVirus, Web Filtering, and a FortiClient profile. This configuration assumes that a connection has already been established between the FortiSandbox Appliance and the FortiGate.

1. Go to **Security Fabric > Settings** and confirm that **Sandbox Inspection** is enabled and the **FortiSandbox Appliance** is connected.
2. Go to **Security Profiles > AntiVirus** and edit the default profile. Under **Inspection Options**, select **All Supported Files** to be sent for inspection and enable **Use FortiSandbox Database**. You have the option of withholding files by name or pattern. Select **Apply**.
3. Go to **Security Profiles > Web Filter** and edit the default profile. Under **Static URL Filter**, enable **Block malicious URLs discovered by FortiSandbox**. Select **Apply**.
4. Go to **Security Profiles > FortiClient Compliance** and edit the default profile. Under **Security Posture Check**, enable **Realtime Protection**. Next, enable **Scan with FortiSandbox**. Select **Apply**.
5. Go to **Policy & Objects > IPv4 Policy** and view the policy list. If a policy has AntiVirus and Web Filtering profiles scanning applied, the profiles will be listed in the **Security Profiles** column. If scanning needs to be added to any security policy (excluding the **Implicit Deny** policy) select the **+** button in the **Security Profiles** column for that policy, then select the default **AntiVirus Profile**, the default **Web Filter Profile**, the appropriate **Proxy Options**, and select the **deep-inspection** profile for **SSL/SSH Inspection** (to ensure that encrypted traffic is inspected).
6. Select **OK**.

Results

If your FortiGate discovers a suspicious file, it will be sent to the FortiSandbox. To view information about the files that have been sent on the FortiGate, go to **FortiView > FortiSandbox** to see a list of file names and current status.

To view results on the FortiSandbox, go to the **Dashboard** and view the **Scanning Statistics** widget. There may be a delay before results appear on the FortiSandbox.

Open FortiClient using a Windows PC on the internal network. Make sure it is registered to your FortiGate. Go to the **AntiVirus** tab and open **Settings**. You will see that the **Realtime Protection** settings match the FortiClient profile configured on the FortiGate. These settings cannot be changed using FortiClient.

If a PC running FortiClient downloads a suspicious file that the FortiSandbox determined was malicious, a quarantine would be applied automatically. While the quarantine is in effect, FortiClient cannot be shutdown on the PC. It can not be uninstalled or unregistered from the FortiGate. The quarantine can only be released from the FortiClient Monitor on the FortiGate.

Sandbox Inspection FAQ

The following are some frequently asked questions about using sandbox inspection with FortiSandbox and FortiGate.

Why is the FortiSandbox Cloud option not available when sandbox inspection is enabled?

This option is only available if you have already created a FortiCloud account. For more information, see the [FortiCloud documentation](#).

Why don't results from FortiSandbox Cloud appear in the FortiGate GUI?

Go to **Log & Report > Log Settings** and make sure **Send Logs to FortiCloud** is enabled and **GUI Preferences** is set to **Display Logs from FortiCloud**.

Why are the FortiSandbox Appliance VMs inactive?

Make sure that port 3 on the FortiSandbox has an active Internet connection. This is required in order to active the FortiSandbox VMs.

Why aren't files are being scanned by FortiSandbox?

Make sure an AntiVirus profile that sends files to FortiSandbox is enabled for all policies that require sandbox inspection.

Is FortiSandbox supported by FortiGate when in NAT or Transparent mode?

Yes, both NAT and Transparent mode are supported.

Are FortiGates behind a NAT device supported? If so how many?

Yes, multiple FortiGates can be supported in-line with FortiSandbox. Currently, there is a limitation where the FortiSandbox will see all FortiGates only as one device so there is no way to differentiate reports but all material will be sent.

If the FortiGate has a dynamic IP, will the FortiSandbox automatically update the FortiGate?

Yes. Dynamic IPs™ are supported and the FortiGate will not have to be reconfigured on the FortiSandbox each time.

Chapter 20 - Fortinet Security Fabric

Introduction

The Fortinet Security Fabric is an end-to-end security solution that gives you control, integration, and easy management of security across your entire organization. The Security Fabric provides an intelligent architecture that interconnects discrete security solutions into an integrated whole to detect, monitor, block, and remediate attacks across the entire enterprise attack surface.

This document is a complete reference guide for the Security Fabric, including an overview of what the Security Fabric is, what devices are included in the Security Fabric and how they work together to secure your network, and how to configure and manage the Security Fabric.

What's new in FortiOS 6.0.2

The following list contains new Fortinet Security Fabric features added in FortiOS 6.0.2:

Automation features

- You can now test automation stitches in the GUI or by using the `diagnose automation test` command.
- When an automation stitch is triggered, the FortiGate creates an event log.

For more information, see ["Automation stitches" on page 2349](#).

Fabric Connector features

- FortiOS supports SDN Connectors to Google Cloud Platform (GCP).
- SDN Connectors to Amazon Web Services no longer require setting a VPC ID.
- SDN Connectors to Microsoft Azure no longer require setting an Azure subscription ID or Azure resource group.
- You can set the region for Azure to the Germany Azure Server or the US Government Azure Server.

For more information, see ["Fabric Connectors" on page 2362](#).

What's new in FortiOS 6.0.1

The following list contains new Fortinet Security Fabric features added in FortiOS 6.0.1:

New features

- Chaining and delaying actions for AWS Lambda and webhook
- Diagnose commands for automation stitches
- Available services for Fabric Connectors
- Verifying Fabric Connector status
- FortiManager in backup mode

6.0.1 GUI changes

- The options to configure single sign-on are now located at **Security Fabric > Fabric Connectors**.
- Automation stitches are available for FortiGate devices that don't belong to a Security Fabric.
- Two new triggers are available: **Security Rating Summary** and **AV & IPS DB Update**.
- The **Event Log** trigger now shows a list of events that can be used as triggers.
- The **FortiExplorer Notification** action now has warning and information message options.
- The **IOC level threshold** option is now called the **Threat level threshold**.
- The triggers for **Conserve Mode** and **High CPU** are now available only in the CLI.

What's new in FortiOS 6.0.0

The following list contains new Fortinet Security Fabric features added in FortiOS 6.0:

- [Automation stitches](#)
- [Security Fabric Rating license](#)
- [To authorize serial numbers of devices from the root FortiGate](#)
- [Joining the Security Fabric by device request](#)
- For Physical and Logical Topology enhancements, see:
 - [The WAN Cloud icon](#)
 - [Switch stacking](#)
 - [FortiAP and FortiSwitch integrations](#)
 - [Distinguishing client traffic from server traffic](#)
 - [Using the Search bar to find information in the topology views](#)
- [FortiMail Stats widget](#)
- [Desynchronizing the FortiAnalyzer, FortiSandbox, and FortiManager](#)
- [Fabric Connectors](#)

Fortinet Security Fabric overview

The Fortinet Security Fabric provides a visionary approach to security that allows your organization to deliver intelligent, powerful, and seamless security. Fortinet offers security solutions for endpoints, access points, network elements, the data center, applications, cloud, and data, designed to work together as an integrated Security Fabric that can be integrated, analyzed, and managed to provide end-to-end protection for your network. Your organization can also add third-party products that are members of the Fabric-Ready Partner Program to the Security Fabric.

All elements in the Security Fabric work together as a team to share policy, threat intelligence, and application flow information. This collaborative approach expands network visibility and provides fast threat detection in real time and the ability to initiate and synchronize a coordinated response, no matter which part of the network is being compromised. The Security Fabric allows your network to automatically see and dynamically isolate affected devices, partition network segments, update rules, push out new policies, and remove malware.

The Security Fabric is designed to cover the entire attack surface and provide you with complete visibility into your network. It allows you to collect, share, and correlate threat intelligence between security and network devices,

centrally manage and orchestrate policies, automatically synchronize resources to enforce policies, and coordinate a response to threats detected anywhere across the extended network. The unified management interface provides you with cooperative security alerts, recommendations, audit reports, and full policy control across the Security Fabric that will give you confidence that your network is secure.

Access security

The Security Fabric secures the access layer of your organization's network. It integrates various access points in a network, such as endpoints, applications, the cloud, and IoT devices, regardless of their distribution, into an end-to-end solution that covers all attack surfaces.

Secure access architecture extends coordinated security policies to the edge of the wired and wireless network, where most vulnerabilities are targeted. It protects the access layer, guarding against data breaches and security threats from both internal user devices and IoT products.

Client security

Client security, through FortiClient, provides easy-to-manage, automated, fully customizable endpoint security for various devices. FortiClient provides end-to-end threat visibility and control by natively integrating endpoints into the security architecture and offers unified endpoint features, including compliance, protection, and secure access. It also offers integrated patch management and vulnerability shielding to harden all endpoints.

FortiClient integrates with the Security Fabric to provide real-time actionable visibility to stop threats to your organization's network at the endpoints.

For more information about FortiClient, see <http://www.forticlient.com/>.

Application security

The Security Fabric protects your organization's sensitive and proprietary data that is managed by applications, and ensures the security and availability of your organization's applications. It allows Fortinet application security products, and those of third-party vendors, to work together to boost security across core networks, remote devices, and the cloud. This provides your organization with a network architecture that is secure, aware, actionable, scalable, and open.

Fortinet's robust and integrated application security solution provides a complete end-to-end high-performance solution that protects your organization's valuable information by using a combination of Fortinet products which are deeply integrated into the Security Fabric for direct communications. These products include web application firewalls for application security, DDoS attack mitigation appliances for DDoS protection, advanced application delivery controllers (ADCs) to meet the demands of secure application traffic, sandboxing to isolate malicious code for inspection, and email security gateways that can detect and prevent email-borne threats from getting to your users.

Cloud security

The Security Fabric is designed to extend deep into different cloud environments to ensure that policies are consistent and enforced across all distributed resources. Within the unified security architecture, virtual firewalls can be deployed across private, public, and hybrid clouds to establish north-south and east-west microsegmentation. The Security Fabric weaves cloud applications into the broader environment, governed by seamless, universal security and compliance policies and managed using transparent visibility across the entire attack surface. Combining Fortinet Cloud Security with an existing enterprise firewall deployment extends the

same powerful security, as well as the same intelligence and dynamic risk mitigation to applications located either in the cloud or on-premise.

NOC and SOC security

Fortinet's security operations center solution covers both IT and security risk management across your entire organization. The solution is a comprehensive approach to managing risk that includes adaptive awareness of the threat landscape, rapid local and global threat detection, reduced complexity in managing alerts and alarms, and reporting and analytics so you can better understand how your organization's risk profiles are being managed.

When Fortinet devices are unified into a Security Fabric, with compatible operating systems and shared intelligence, the security operations solution also includes information from network elements beyond Fortinet devices. The solution allows your network operations center (NOC) and security operations center (SOC) to share information, integrating and cross-correlating the data from each operations center. This additional context, visibility, and focus breaks down the barrier between your NOC and SOC, and gives you a comprehensive view across your entire Security Fabric so you can quickly find and respond to threats.

Advanced threat intelligence

Fortinet's Advanced Threat Protection (ATP) solution allows your organization to detect and mitigate against threats, both known and unknown, and share that information locally to deliver a coordinated defense.

The ATP solution relies on many types of security technologies, products, and research applied from the network edge through to endpoint devices. To deliver the most effective protection, they are integrated with other security elements from the Enterprise Firewall and Cloud solutions to work together automatically, continuously handing off data from one element to the next to identify, evaluate, and respond to attacks across the entire environment.

The ATP framework delivers end-to-end protection across the attack chain and consists of three elements: prevention, detection, and mitigation, with continuous threat monitoring and analytics from FortiGuard Labs.

For more information about the Advanced Threat Protection Solution, see <http://www.fortinet.com/atp>.

Partner API

The Fortinet Fabric-Ready Partner Program is an interoperability program for technology alliance partners. Technology alliance partners integrate their products with the Fortinet Security Fabric using Fortinet Security Fabric APIs. Their products are then able to actively collect and share threat and mitigation information from one end of the security solution to the other, which improves threat intelligence, enhances overall threat awareness, and broadens threat response.

Inclusion in the program means that Fabric-Ready Partners have collaborated with Fortinet and leveraged the Fortinet Security Fabric APIs to develop and validate integrated end-to-end security solutions that are ready for deployment.

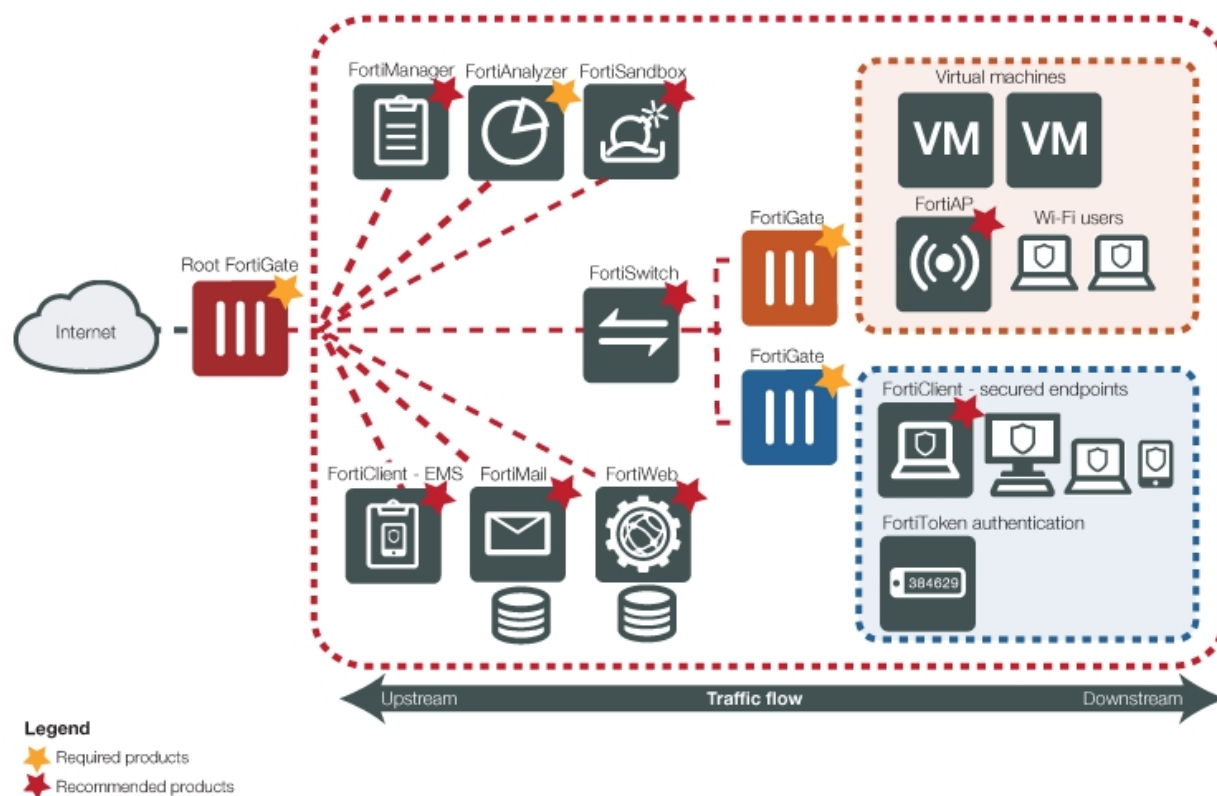

The Fabric-Ready Partner Program allows Fortinet technology alliance partners to build on Fortinet products and solutions which help your organization get even more value from your security deployment.

For more information about the Fortinet Fabric-Ready Partner Program, see

<https://www.fortinet.com/partners/partnerships/alliance-partners.html>

The Security Fabric solution components

The Fortinet Security Fabric consists of various components that work together to form the Security Fabric that secures your organization's network. The following diagram shows an example Security Fabric that contains both required and recommended Fortinet products:

Devices in the Security Fabric

The Security Fabric implementation consists of:

- Required devices
- Recommended devices
- Optional devices

Required devices

The following table shows devices that are required in the Fortinet Security Fabric:

Device	Description
FortiGate	<p>FortiGate is a next-generation firewall (NGFW) that provides enterprise-class protection against network, content, and application-level threats.</p> <p>FortiGate devices are the core of the Security Fabric and can have one of the following roles in the Security Fabric:</p> <ul style="list-style-type: none"> • Root FortiGate: The root FortiGate is the main component in the Security Fabric. It is typically located on the edge of the network and connects the internal devices and networks to the Internet through your ISP. From the root FortiGate, you can see information about the entire Security Fabric from the Physical and Logical Topology pages in the Security Fabric menu. • Internal Segmentation Firewall (ISFW): After a root FortiGate is installed, all other FortiGate devices in the Security Fabric act as ISFWs. An ISFW is a firewall that is located at strategic points in your internal network, rather than on the network edge. This allows extra security measures to be taken around key network components, such as servers that contain valuable intellectual property. ISFW FortiGate devices create network visibility by sending traffic and information about the devices that are connected to them to the root FortiGate.
FortiAnalyzer	<p>FortiAnalyzer collects, analyzes, and correlates log data from Fortinet devices throughout your organization's network, and allows you to view all firewall traffic and generate reports from a single console.</p> <p>FortiAnalyzer gives you increased visibility into your organization's network and simplifies network logging by storing and displaying all log information in one place. It provides centralized monitoring and awareness of threats, events, and network activity by collecting and correlating logs from Security Fabric devices, such as FortiGate, FortiClient, FortiSandbox, FortiWeb, and FortiMail. This gives you a deeper and more comprehensive view across your entire Security Fabric. You can use the robust security alert information and real-time threat intelligence that FortiAnalyzer provides to quickly identify and respond to security threats across your organization's network.</p>

Recommended devices

The following table shows devices that Fortinet recommends you have in the Fortinet Security Fabric:

Device	Description
FortiAP	<p>FortiAP is a wireless access point that provides integrated, secure, identity-driven wireless LAN access for your organization's network.</p> <p>You can add FortiAP devices to extend the Security Fabric to your wireless devices. Devices connected to a FortiAP appear in the Physical and Logical Topology pages in the Security Fabric menu.</p>

Device	Description
FortiClient	<p>FortiClient adds endpoint control to devices that are located in the Security Fabric, allowing only traffic from compliant devices to flow through the FortiGate. This is done through FortiClient compliance profiles.</p> <p>In the Security Fabric, FortiClient compliance profiles are applied by the first FortiGate that a device's traffic flows through. This is often an ISFW FortiGate. Device registration and on-net status information for a device that is running FortiClient appears only on the FortiGate that applies the FortiClient profile to the device.</p>
FortiClient EMS	<p>FortiClient Enterprise Management Server (EMS) is a security management solution that provides scalable and centralized management of multiple endpoint devices.</p> <p>FortiClient EMS is used in the Security Fabric to provide visibility across your network, to securely share information, and assign security profiles to endpoints.</p>
FortiMail	<p>FortiMail is a secure email gateway that uses various threat prevention methods, including antispam, antimalware, sandboxing, and anomaly detection.</p> <p>FortiMail integrates with other Fortinet products, as well as third-party virtual and cloud platforms, to help establish a seamless Security Fabric across the entire attack surface. FortiMail anti-spam processing helps offload other devices in the Security Fabric that would typically carry out this process.</p>
FortiManager	<p>FortiManager is an easy-to-use, single pane of glass management console, that gives you total visibility, full control, and complete protection of your organization's network.</p> <p>Using the FortiManager in the Security Fabric allows you to simplify the network management of devices in the Security Fabric by centralizing management access in a single device. This allows you to easily control the deployment of security policies, FortiGuard content security updates, firmware revisions, and individual configurations for devices in the Security Fabric.</p>
FortiSandbox	<p>FortiSandbox is an advanced threat protection appliance that improves your security architecture by identifying and validating threats in a separate, secure environment.</p> <p>You can add FortiSandbox to your Security Fabric to improve security with sandbox inspection. Sandbox integration allows FortiGate devices in the Security Fabric to automatically receive signature updates from FortiSandbox and add the originating URL of any malicious file to a blocked URL list.</p>

Device	Description
FortiSwitch	<p>FortiSwitch is a secure access switch that can be integrated into the Fortinet Security Fabric through the FortiLink protocol. FortiLink allows FortiSwitch ports to become logical extensions of the FortiGate. This allows the FortiGate to auto-discover a connected FortiSwitch for provisioning, including the attachment of policy to ports or VLANs. With an integrated access layer, the FortiGate provides consolidated visibility and reporting with Physical and Logical Topology views of the Security Fabric in the Security Fabric menu.</p> <p>You can add a FortiSwitch to the Security Fabric when it is managed by a FortiGate within the Security Fabric, and connected to an interface that uses FortiTelemetry.</p> <p>Devices connected to the FortiSwitch appear in the Physical and Logical Topology pages in the Security Fabric menu, and security features, such as FortiClient compliance profiles, are applied to them.</p>
FortiWeb	<p>FortiWeb is a web application firewall that protects hosted web applications from attacks that target known and unknown exploits.</p> <p>In the Security Fabric, FortiWeb defends the application attack surface from attacks that target application exploits. You can also configure FortiWeb to apply web application firewall features, virus scanning, and web filtering to HTTP traffic to help offload other devices in the Security Fabric that would typically carry out these processes.</p>

Optional devices

The following table shows devices that are optional in the Fortinet Security Fabric:

Device	Description
Other Fortinet products	Many other Fortinet products can be added to the Security Fabric, including FortiAuthenticator, FortiToken, FortiCache, and FortiSIEM.
Third-party products	Third-party products that belong to the Fortinet Fabric-Ready Partner Program .

Security Fabric topology views

You can see the Security Fabric topology in the root FortiGate GUI. Two viewing options are available: the Physical Topology view and the Logical Topology view.

The Physical Topology view displays the physical structure of your network, by showing the devices in the Security Fabric and the connections between them. The Logical Topology view displays the logical structure of your network, by connection, by showing information about logical and physical network interfaces in the Security Fabric and the interfaces that connect devices in the Security Fabric. Only Fortinet devices are shown in the topology views.

For more information about the topology views, see ["Using the Fortinet Security Fabric" on page 2337](#).

Security Fabric Rating

The Security Fabric Rating provides a method to continually monitor and improve your organization's Security Fabric configuration. The Security Fabric Rating is a feature on the FortiGate that analyzes your Security Fabric deployment, identifies potential vulnerabilities, and highlights best practices that you can use to improve the overall security and performance of your network.

Using the Security Fabric Rating helps you to:

- Tune your network configuration
- Deploy new hardware and software
- Have more visibility into your network
- Gain more control over your network
- Adhere to your organization's compliance requirements

The Security Fabric Rating provides a Security Fabric Score based on how many security checks your network passes and fails during the test. By checking the Security Fabric Score, and implementing the recommendations, you can have confidence that your network is getting more secure over time.

For more information about running a Security Fabric Rating check, see ["Using the Fortinet Security Fabric" on page 2337](#).

FortiTelemetry

FortiTelemetry is a protocol that Fortinet products in the Security Fabric use to communicate with each other. It connects Security Fabric devices and allows dynamic status updates to travel between them. The Security Fabric uses FortiTelemetry to link various security sensors and tools together to collect, coordinate, and respond to malicious behavior anywhere it occurs in your network in real time.

You must enable FortiTelemetry on interfaces that connect Fortinet devices in the Security Fabric.

Configuring the Fortinet Security Fabric

This section contains information about how to configure a Fortinet Security Fabric:

- [Forming the Security Fabric](#)
- [Setting up data collection with FortiAnalyzer](#)
- [Adding a FortiSandbox to the Security Fabric](#)
- [Adding a FortiManager to the Security Fabric](#)
- [Adding FortiClient EMS to the Security Fabric](#)

System requirements

To set up the Security Fabric in FortiOS 6.0, the devices that you want to include in the Security Fabric must meet the Product Integration and Support requirements in the [FortiOS Release Notes](#).

Some features of the Security Fabric are available only in certain firmware versions and models. Not all FortiGate models can run the FortiGuard Security Rating Service if they are the root FortiGate in a Security Fabric. For more information, see the Special Notices in the [FortiOS Release Notes](#).

For more information about upgrading the Security Fabric to version 6.0, see the [Fortinet Security Fabric Upgrade guide](#).

Prerequisites

- Determine which devices you want to have in the Security Fabric.
- Ensure devices meet the [Configuring the Fortinet Security Fabric](#)
- If devices are not already installed in your network, complete basic installation and configuration tasks by following the instructions in the device documentation.
- Disable virtual domains (VDOMs) on all FortiGate devices that you want to add to the Security Fabric.
- Configure all FortiGate devices that you want to add to the Security Fabric to use NAT/route mode.

Forming the Security Fabric

To form the Security Fabric, you configure the root FortiGate and then the ISFW FortiGate devices. Although you can configure any of the FortiGate devices in the Security Fabric to be the root FortiGate, you typically configure the edge FortiGate as the root FortiGate. This setup allows you to view the full topology of the Security Fabric from the top down.

The following procedures include configuration steps for a typical Security Fabric implementation, where the root FortiGate is the edge FortiGate and the ISFW FortiGate devices are all FortiGate devices that are downstream from the root FortiGate.

Adding devices to the Security Fabric

You can easily and securely allow FortiGate, FortiAP and FortiSwitch to join the Security Fabric without sharing the password of the root FortiGate. You can authorize these device serial numbers from the root FortiGate or allow the device to join by request. New authorization requests include the serial number of the device, the device IP address, and a list of High Availability (HA) members.

HA members can contain up to four serial numbers and this list is used to ensure that, in the event of failover, the secondary FortiGate is still authorized.

After a FortiGate or FortiWiFi joins the Security Fabric, any connected FortiAP or FortiSwitch automatically appears in the topology. You can then authorize these additional devices from the FortiGate or FortiWiFi they're connected to or the root FortiGate.

To authorize serial numbers of devices from the root FortiGate

When you add the serial number of a Fortinet device to the trusted list on the root FortiGate, the device can join the Security Fabric as soon as it connects. After you authorize the new FortiGate, additional connected FortiAP and FortiSwitch devices automatically appear in the topology tree. From the topology tree, it's easier for you to authorize them with one click.

To authorize a FortiGate or a FortiWiFi from the root FortiGate:

1. Connect to the root FortiGate. To add the serial number of the new FortiGate to the Security Fabric trusted list, enter the following commands:

```
config system csf
  config trusted-list
    edit <serial-number>
  end
end
```

2. To enable FortiTelemetry on an interface, go to **Network > Interfaces** and edit the interface that connects to the FortiGate or FortiWiFi you are authorizing. Under Administrative Access, enable **FortiTelemetry**. For best practices, under Networked Devices, you can also enable **Device Detection**.
3. Connect to the FortiGate you're adding to the Security Fabric and set the following settings on the **Security Fabric > Settings** page:

FortiGate Telemetry	Enable FortiGate Telemetry .
Group name	Set the Group name to the same Security Fabric group name that's configured on the root FortiGate.
Group password	Leave this field blank.
Connect to upstream FortiGate	Enable Connect to upstream FortiGate .
FortiGate IP	Enter the IP address of the root FortiGate or upstream FortiGate you're connecting to.
Apply	Select Apply .

4. Connect to the root FortiGate. Open the **Security Fabric > Settings** page and verify that the FortiGate that you added appears in the Security Fabric Topology.

Joining the Security Fabric by device request

Your device can request to join the Security Fabric from another FortiGate. However, you must have the group name and the IP address of the root FortiGate. The administrator of the root FortiGate in the Security Fabric

must also authorize your device before it can join the Security Fabric.

The root FortiGate must already have FortiTelemetry enabled on the interface that the device is connecting to.

To enable FortiTelemetry on an interface, go to **Network > Interfaces** and edit the interface that connects to the FortiGate or FortiWiFi you are authorizing. Under Administrative Access, enable **FortiTelemetry**. For best practices, under Networked Devices, you can also enable **Device Detection**.

To join the Security Fabric by device request - GUI:

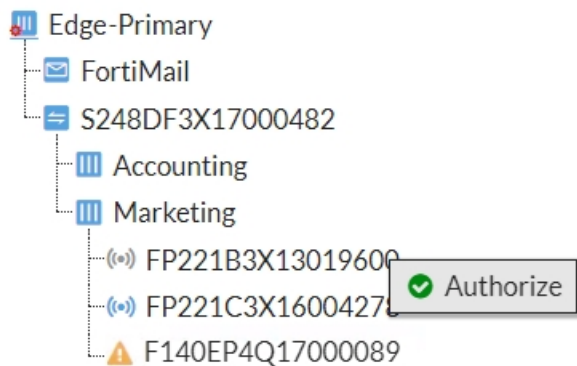

1. Connect to the unauthorized FortiGate or FortiWiFi, and go to **Security Fabric > Settings**.
2. From the Security Fabric Settings page, enable **FortiGate Telemetry**.
3. Enter the group name in the **Group name** field.
4. Leave the **Group password** blank.
5. To connect, enable **Connect to upstream FortiGate**.
6. Set the **FortiGate IP** to the IP address of the root FortiGate or upstream FortiGate that you want to connect to, and select **Apply**.
7. Connect to the root FortiGate and verify that the unauthorized FortiGate appears in the topology tree in **Security Fabric > Settings**. Hover over the unauthorized FortiGate and the tool tip shows the **Status** as **Waiting for Authorization**.
8. To authorize, click on the unauthorized FortiGate and select **Authorize**.

You can also allow other Fortinet devices to join the Security Fabric. You can authorize both FortiAP and FortiSwitch in the Security Fabric with one click. When you connect a FortiAP or FortiSwitch to an authorized FortiGate or FortiWiFi, the device automatically appears in the topology tree.

To authorize FortiAP and FortiSwitch devices

1. The topology tree is in the Security Fabric Settings page and in the Security Fabric Status widget on the Dashboard page. From either widget, click on the grayed out device icon to authorize or deauthorize it. Authorized devices turn blue and unauthorized products disappear from the topology tree.
2. Connect to the upstream FortiGate that the FortiAP or FortiSwitch is connected to.

The image below shows an unauthorized FortiAP in the topology widget:

Note: You can also deauthorize FortiMail from the topology tree, however you must initially authorize FortiMail in the **Security Fabric > Settings** menu.

The following image shows FortiMail options:

Note: You can't authorize or deauthorize a FortiGate from the topology tree widget. You must disable FortiGate telemetry from the FortiGate you wish to deauthorize, or set the serial number to deny on the root FortiGate to remove it from the Security Fabric topology tree.

The following image shows FortiGate options:

Deauthorizing a device

You can deauthorize a device to remove it from the topology tree widget in the Security Fabric Settings page and in the Security Fabric Dashboard.

To deauthorize a FortiGate or FortiWiFi from the root FortiGate - GUI:

1. Connect to the root FortiGate.
2. To deauthorize the serial number of a trusted FortiGate or FortiWiFi, enter the following CLI commands:

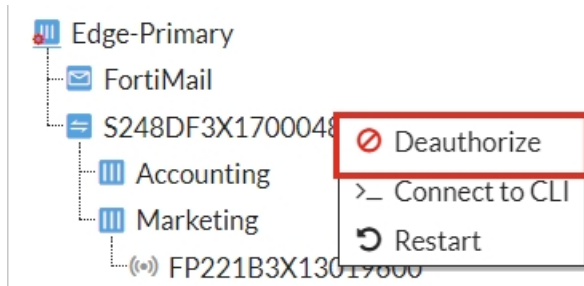

```
config system csf
...
config trusted-list
    edit <serial-number>
        set action deny
    end
end
```

To leave the Security Fabric from a downstream FortiGate or FortiWiFi

1. Connect to the FortiGate or FortiWiFi that you want to deauthorize, and go to **Security Fabric > Settings**.
2. Disable **FortiGate Telemetry**.
3. **Apply** your changes.

To deauthorize a FortiSwitch, FortiAP, or FortiMail - GUI:

1. Connect to the upstream FortiGate and go to **Security Fabric > Settings** to see the topology. Alternatively, you can use the Security Fabric topology widget located in **Dashboard > Main**.
2. Click on the device and select **Deauthorize**. This removes the device from the topology tree.

After deauthorization, the serial numbers of the rejected device are saved in a trusted list that's available only in the CLI. You can view the trusted list using the `show system csf` command. The following example shows how the deauthorized FortiSwitch (from the image above) appears in the `trusted-list` with the action set to deny.

Syntax

```
show system csf
config system csf
  set status enable
  set group-name "Office-Security-Fabric"
  set group-password ENC 1Z2X345V678
  config trusted-list
    edit "FGT6HD391806070"
    next
    edit "S248DF3X17000482"
      set action deny
    next
  end
end
```

Add FortiAnalyzer to the root FortiGate of the Security Fabric

1. In the root FortiGate GUI, select **Security Fabric > Settings**.
2. In the Security Fabric Settings page, enable **FortiGate Telemetry**.
3. **FortiAnalyzer Logging** is automatically enabled.
4. In the **IP address** field, enter the IP address of the FortiAnalyzer that you want the Security Fabric to send logs to. If you select **Test Connectivity**, and this is the first time that you are connecting the FortiGate to the FortiAnalyzer, you will receive an error message because the FortiGate has not yet been authorized on the FortiAnalyzer. You can configure this authorization when you configure the FortiAnalyzer.
5. In the **Upload option** field, select the option for how often you want the FortiGate to send logs to the FortiAnalyzer.
6. If you want log transmissions encrypted, enable the **Encrypt log transmission** option. The log transmissions are encrypted using SSL.
7. Select **Apply**.

Additional CLI commands

You can use the following diagnose commands to view pending authorization requests, accept or deny authorization requests, or troubleshoot commands.

To view pending authorization requests on the root FortiGate - CLI:

```
diagnose system csf authorization pending-list
```

To accept or deny authorization requests to join the Security Fabric - CLI:

```
diagnose system csfd authorization {accept | deny} <serial-number-value>
```

where `serial-number-value` is the serial number of the device that has sent an authorization request to join the Security Fabric.

To view downstream device information - CLI:

```
diagnose system csf downstream
```

Configure ISFW FortiGate devices for the Security Fabric

You must have the group password of the root FortiGate to configure ISFW FortiGate devices for the Security Fabric.

1. In the ISFW FortiGate GUI, select **Security Fabric > Settings**.
2. In the Security Fabric Settings page, enable **FortiGate Telemetry**.
3. In the **Group name** field, enter the group name that you set for the Security Fabric.
4. In the **Group password** field, enter the group password that you set for the Security Fabric.
5. Enable the **Connect to upstream FortiGate** option.
6. In the **FortiGate IP** field, enter the IP address of the port on the upstream FortiGate that this FortiGate connects to. Depending on your network topology, the upstream FortiGate is another ISFW FortiGate or the root FortiGate. The FortiAnalyzer setting is automatically enabled. Settings for the FortiAnalyzer will be retrieved when the ISFW FortiGate connects to the root FortiGate.
7. Select **Apply**.
8. Repeat this procedure on every ISFW in the Security Fabric.

Setting up data collection with FortiAnalyzer

To set up data collection for the Security Fabric, you enable device detection on ISFW FortiGate devices and then connect the FortiAnalyzer to the Security Fabric.

You enable device detection on the interfaces of the ISFW FortiGate devices where you want the devices attached to those interfaces added to the Security Fabric. Only devices detected on those interfaces are shown in the Security Fabric topology views.

Connecting the FortiAnalyzer to the Security Fabric allows the Security Fabric to show historical data for the Security Fabric topology and logs for the entire Security Fabric.

Enable device detection on ISFW FortiGate devices

1. In the ISFW FortiGate GUI, select **Network > Interfaces**.
2. Select the interface that you want to enable device detection on.
3. Select **Edit** and in the **Networked Devices** section, enable **Device Detection**.
4. Select **OK**.
5. Repeat this procedure for every interface that you want to enable device detection on.

Desynchronizing the FortiAnalyzer, FortiSandbox, and FortiManager

If you want to add devices manually, you can edit the **Source IP** for downstream FortiGate devices in the **Central Management** settings. The **Central Management** settings are located in **Security Fabric > Settings**.

However, if you change the **Source IP**, you must change the log settings to `local`.

If you don't want to automatically synchronize the configurations for FortiAnalyzer, FortiSandbox, and FortiManager, you can change the default system settings of the Security Fabric to use local settings.

To use local system settings - CLI:

```
config system csf
    set configuration-sync local
end
```

Where you set the following variables:

Option	Description
default	Synchronizes the configuration for FortiAnalyzer, FortiSandbox, and Central Management to the root FortiGate.
local	Doesn't synchronize the configuration with the root FortiGate, and you must configure settings individually.

Connect the FortiAnalyzer to the Security Fabric

Ensure that all FortiGate devices in the Security Fabric are registered with the same FortiAnalyzer.

1. In the FortiAnalyzer GUI, select **System Settings > Network**.
2. Select **All Interfaces**.
3. Select the port that connects to the root FortiGate.
4. Select **Edit**.
5. In the **IP Address/Netmask** field, enter the IP address used for the Security Fabric configuration on the root FortiGate.
6. In the **Default Gateway** field, enter the IP address of the interface on the root FortiGate that the FortiAnalyzer connects to.
7. Select **OK**.
8. Select **System Settings > Device Manager**.
The FortiGate devices are listed as **Unregistered**.
9. Select the root FortiGate and the ISFW FortiGate devices in the Security Fabric.
10. Select **+ Add Device**.
The FortiGate devices are now listed as **Registered**.
A warning icon will appear beside the root FortiGate, because the FortiAnalyzer requires administrative access to the root FortiGate in the Security Fabric.
11. In the **Authentication** window, complete the **Admin User** and **Password** fields to authenticate the Security Fabric.
After the FortiAnalyzer authenticates the Security Fabric, the FortiAnalyzer shows the full Security Fabric topology.

You can verify that the FortiAnalyzer configuration is successful by selecting **Security Fabric > Settings** on the root and ISFW FortiGate devices. The **Storage usage** field in the **FortiAnalyzer Logging** section should now show storage usage information.

It is recommended that you create a user account for the FortiAnalyzer.

Adding a FortiSandbox to the Security Fabric

The Security Fabric supports both FortiSandbox Appliance and FortiSandbox Cloud. To use FortiSandbox Cloud, you must first activate a FortiCloud account.

To use FortiSandbox in a Security Fabric, you connect the FortiSandbox to the Security Fabric and then configure an antivirus profile to send files to the FortiSandbox. You can also use sandbox inspection in web filtering and FortiClient compliance profiles.

Connect the FortiSandbox to the Security Fabric

You configure FortiSandbox settings on the root FortiGate in the Security Fabric. After you configure these settings, the root FortiGate pushes them to the other FortiGate devices in the Security Fabric.

1. On the root FortiGate, go to **Security Fabric > Settings**.
2. Enable **Sandbox Inspection**.
3. Select either **FortiSandbox Appliance** or **FortiSandbox Cloud**.
4. If you're using a FortiSandbox Appliance, set **Server** to the IP address for the FortiSandbox.
5. Select **Apply**.

To authorize the FortiSandbox appliance, configure the following:

1. On the FortiSandbox, go to **Scan Input > Device**.
2. Edit the root FortiGate.
3. Under **Permissions & Policies**, select **Authorized**.
4. Select **OK**.
5. Authorize the other FortiGate devices in the Security Fabric.

Configure antivirus profiles

1. Go to **Security Profiles > AntiVirus**.
2. Create a new profile, edit an existing profile, or clone and edit an existing profile.
3. Under **Inspection Options**, set **Send Files to FortiSandbox Appliance/Cloud for Inspection** to **All Supported Files**.
4. Enable **Use FortiSandbox Database**.
5. Select **OK**.

Configure web filter profiles

1. Go to **Security Profiles > Web Filter**.
2. Create a new profile, edit an existing profile, or clone and edit an existing profile.

3. Under **Static URL Filter**, enable **Block malicious URLs discovered by FortiSandbox**.
4. Select **OK**.

Configure FortiClient compliance profiles

1. Go to **Security Profiles > FortiClient Compliance Profiles**.
2. Create a new profile, edit an existing profile, or clone and edit an existing profile.
3. Enable **Security Posture Check**.
4. Enable **Realtime Protection** and **Scan with FortiSandbox**.
5. Select **OK**.

Adding a FortiManager to the Security Fabric

When you add a FortiManager to the root FortiGate in the Security Fabric, it automatically synchronizes with any connected Security Fabric devices that are downstream. To add FortiManager to the Security Fabric, you must configure central management on the root FortiGate. Once you configure these settings, the root FortiGate pushes them to the other FortiGate devices in the Security Fabric. The FortiManager must have Internet access.

The following steps also ensure that the FortiGate can receive antivirus and IPS updates and allow remote management through the FortiManager system or FortiCloud service. The FortiManager device provides remote management of a FortiGate over TCP port 541. You must enable the FortiGate management option so the FortiGate can accept management updates to firmware and FortiGuard services.

Registering a FortiGate ensures that it receives updates to FortiGuard services. It also gives you access to technical support. To register the FortiGate, visit the [Fortinet Support](#) website.

To add a FortiManager to the root FortiGate - GUI:

1. On the root FortiGate, go to **Security Fabric > Settings**.
2. Enable **Central Management**.
3. In the **Type** field, select **FortiManager**.
4. Enter the **IP/Domain Name** for the FortiManager.
5. Select **Apply**.
6. On the FortiManager, go to **Device Manager**. The FortiGate devices in the Security Fabric are listed as **Unregistered Devices**.
7. Select the FortiGate devices, then select **+Add**.
8. Select **OK**.

To configure the FortiGate - CLI:

```
config system central-management
  set type fortimanager
  set fmg {<IP_address> | <FQDN_address>}
end
```

For more information about using FortiManager, see "[Central management with FortiManager](#)" on page 2368.

Adding FortiClient EMS to the Security Fabric

You can configure endpoint control for your Security Fabric using FortiClient Endpoint Management System (EMS).

If you disable the **FortiClient Endpoint Management System (EMS)** option found on the **Security Fabric > Settings** page, it deletes all previously configured EMS server entries.

To configure an EMS Server - GUI:

1. To enable endpoint control, go to **System > Feature Visibility** and under Security Features, enable **Endpoint Control**. The FortiClient Endpoint Management System (EMS) section appears in the **Security Fabric > Settings** page.
2. Go to **Security Fabric > Settings** and enable **FortiClient Endpoint Management System (EMS)**.
3. Select the **+** to add it and enter the following:

Name	Enter the name of the EMS server.
Address	Select the FortiClient EMS address from the drop-down menu or select the + to create a new IP address or hostname.
Serial Number	
REST API Calls	

You can add a maximum of 16 EMS Servers.

4. **Apply** your changes.

To configure endpoint control settings - CLI:

```
config endpoint-control settings
    set forticlient-ems-rest-api-call-timeout <value>
end
```

where the value is set between 500 to 30000 milliseconds (default of 5000).

To configure a FortiClient Enterprise Management server - CLI:

```
config endpoint-control forticlient-ems
    edit 1
        set address <firewall-address-name>
        set serial-number <FortiClient-EMS-serial-number>
        set listen-port <listen-port-number>
        set upload-port <upload-port-number>
        set rest-api-auth <FortiClient-EMS-REST-API-authentication>
    next
end
```

where the following values are set to:

Variable	Description
listen-port-number	Set the listening port between 1 and 65535. The default port is 8013.
upload-port-number	Set the uploading port between 1 and 65535. The default port is 8014.

To configure FortiClient registration synchronization settings - CLI:

```
config endpoint-control forticlient-registration-synch
  edit <default-name>
    config {forticlient-winmac-setting | forticlient-android-settings | forticlient-ios-
      settings}
  next
end
```

To configure FortiClient endpoint control profiles - CLI:

```
config endpoint-control profile
  edit <profile-name>
    config {forticlient-winmac-setting | forticlient-android-settings | forticlient-ios-
      settings}
    set forticlient-ems-entries <FortiClient-EMS-entry-name>
  next
end
```

For information about further information about FortiClient EMS, see the [FortiClient EMS Administration Guide](#).

Troubleshooting

The following commands can be useful for testing FortiClient EMS settings, including: signing in or out of FortiClient EMS, quarantining clients using EMS REST API, and adding quarantine calls to the queue. For additional troubleshooting commands, see the [FortiOS CLI Reference](#).

- `diagnose endpoint forticlient-ems-rest-api signin <FortiClient-EMS-entry-name>`
- `diagnose endpoint forticlient-ems-rest-api signout <FortiClient-EMS-entry-name>`
- `diagnose endpoint forticlient-ems-rest-api quarantine-by-ipv4 <ipv4> <FortiClient-EMS-entry-name>`
- `diagnose endpoint forticlient-ems-rest-api unquarantine-by-ipv4 <ipv4> <FortiClient-EMS-entry-name>`
- `diagnose endpoint forticlient-ems-rest-api queue-quarantine-ipv4 <ipv4-address> [,<ipv4-address>...] To add multiple entries, separate the entries by a comma (no spaces).`
- `diagnose endpoint forticlient-ems-rest-api queue-unquarantine-ipv4 <ipv4> [,<ipv4-address>...] To add multiple entries, separate the entries by a comma (no spaces).`
- `diagnose debug application fcnacd_ems <integer>`

Using the Fortinet Security Fabric

Once you set up the Security Fabric, there are various Security Fabric features that you can use to improve your network security, including the following:

- [Understanding the Security Fabric dashboard widgets](#)
- [Viewing the Security Fabric topology](#)
- [Running a Security Fabric Rating](#)
- [Automation stitches](#)

Understanding the Security Fabric dashboard widgets

You can add Security Fabric widgets to the dashboard on the root FortiGate. There are three widgets available: the Security Fabric Status widget, the Security Rating widget, and the FortiMail Statistics widget. The widgets allow you to see information about the status of the Security Fabric when you first log in to the FortiGate.

If any of these widgets do not appear on your dashboard, you can add them using the  settings button in the bottom right corner. On the root FortiGate, select **Dashboard > Main** and the settings button appears when your

mouse hovers over any part of the dashboard.  Select **Add Widget** and under **Security Fabric**, click to add the widget.

The Security Fabric Status widget

The Security Fabric Status widget shows a visual summary of many of the devices in the Security Fabric. You can hover over the icons at the top of the widget to get a quick view of the status of the Security Fabric, including the status of FortiTelemetry and devices in the Security Fabric. You can click to authorize FortiAP and FortiSwitch devices that are connected to an authorized FortiGate.

The widget shows the following information:

- The name of your Security Fabric
- Icons indicating the other Fortinet devices that can be used in the Security Fabric:
 - Devices in blue are connected in your network
 - Devices in gray are unauthorized devices that are connected in your network.
 - Devices in red are not detected in your network, but are recommended for the Security Fabric.
 - An attention icon shows a FortiGate or FortiWiFi waiting for Authorization.
- The names of the FortiGate devices in the Security Fabric

The Security Rating widget

The Security Rating widget shows the latest Security Rating for your Security Fabric. You can configure the widget to show either how your organization's Security Fabric rating compares to the ratings of other organizations that belong to the same industry as your organization or all industries. Your organization's industry is determined from your FortiCare account. You can also configure the widget to either show scores that are specific to your organization's region or all regions. The widget shows the Security Rating score by percentile. To receive a Security Rating score, all FortiGate devices in the Security Fabric must have a valid Security Rating License.

FortiMail Stats widget

The FortiMail Stats widget shows mail detection statistics from FortiMail. You can configure the widget to show statistics from a FortiMail in your Security Fabric. If you have more than one FortiMail in your Security Fabric, you can add additional FortiMail Stats widgets to the Dashboard.

This widget shows both the total number and percentage of email messages that the FortiMail identifies as belonging to non-spam, spam, and virus categories. You can filter the statistics by time period, such as the number of messages per year, per month, and per hour.

FortiMail Stats -  FortiMail		Total ▾	⋮
Total		100	
Non-spam		92 (92%)	
Spam		7 (7%)	
Virus		1 (1%)	

Viewing the Security Fabric topology

You can see the Security Fabric topology in the FortiGate GUI, in the Security Fabric menu. You can choose the Physical Topology or Logical Topology views. In both topology views, you can hover over device icons and use filtering and sorting options to see more information about devices and your organization's network. To view the complete network, you must access the topology views on the root FortiGate in the Security Fabric.

You can also see the Security Fabric topology in the FortiAnalyzer GUI. In the FortiAnalyzer GUI, select **Device Manager**. The FortiGate devices in the Security Fabric are shown as part of a Security Fabric group. An asterisk (*) appears beside the root FortiGate in the Security Fabric. To see the topology of the Security Fabric, right-click on the Security Fabric group and select **Fabric Topology**. Only Fortinet devices are shown in the Security Fabric topology views. The following image shows the FortiAnalyzer GUI.

Device Manager ▾				
	4 Devices Total		1 Devices Unregistered	 0 Devices Log Status Down
+ Add Device  Edit  Delete  More ▾  Column Settings ▾				
<input type="checkbox"/>	▲ Device Name	IP Address	Platform	Logs
<input type="checkbox"/>	✕ Office-Security-Fabric			
<input type="checkbox"/>	Accounting	192.168.65.2	FortiGate-140E-POE	  Real Time
<input type="checkbox"/>	Edge*	192.168.65.2	FortiGate-600D	  Real Time
<input type="checkbox"/>	Marketing	192.168.65.2	FortiGate-81E-POE	  Real Time

The WAN Cloud icon

The WAN cloud icon, in the Physical and Logical Topology views, allows you to receive destination data from the following options in the drop-down menu: Internet, owner IP address, and country/region. These options are available only in the Physical Topology view, when you select **Device Traffic** in the menu in the top right corner.

When you set the WAN cloud icon to **Owner**, the destination hosts are simplified to a fixed size donut chart. This chart shows the percentage division between Internal hosts (with private IP addresses) and Internet hosts. To see which color represents each host, hover over either color. To zoom in on the total number of hosts, click on the donut graph. To see more data for owner details in **FortiView > Destinations**, right-click and select **Destination Owner Details**. You can see the Internet Hosts in the screen shot below.

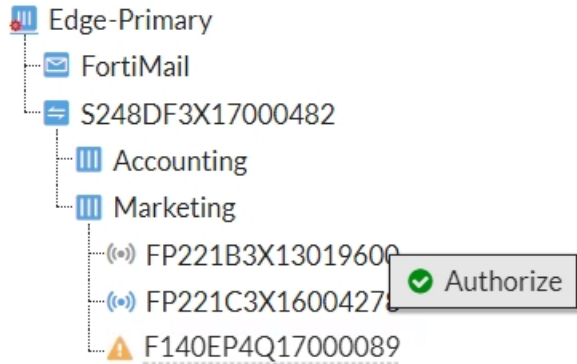

Switch stacking

FortiAP and FortiSwitch links are enhanced in the Security Fabric's Logical and Topological views to show Link Aggregation Groups for the Inter-switch Link (ISL-LAG). This makes it easier to identify which links are physical links and which links are ISL-LAG. To quickly understand connectivity when you look at multiple link connections, ISL-LAG is identified with a thicker single line. To identify ISL-LAG groups with more than two links, you can also look at the port endpoint circles as references.

FortiAP and FortiSwitch integrations

You can see newly discovered FortiAP devices and FortiSwitches in the Security Fabric Topology widget as grayed-out icons, and you can click on any discovered device to authorize it. Once it's authorized, the device icon changes to blue. The following image shows the Security Fabric Topology widget.

The following image shows the same device in the Physical and Logical Topology views.

For an authorized FortiAP, you can right-click to: either **Deauthorize** or **Restart the device**. For an authorized FortiSwitch, you can choose from the following management options: **Deauthorize**, **Connect to CLI**, **Restart** or **Upgrade**.

You can hover over the icon to show the device tooltips. Device tooltips show the connection status and firmware version. FortiSwitch also includes the faceplate and includes the physical port name and number of any devices connected to the FortiSwitch. The following image shows a FortiSwitch device tooltip.

Distinguishing client traffic from server traffic

The Physical and Logical Topology view shows servers and server clusters as rounded square shapes instead of bubbles, and they are grouped separately from endpoint devices to allow you to easily distinguish server traffic from other client traffic. Devices are grouped by device type. For example: Android phones, Apple phones, and Windows PCs.

Identifying compromised hosts from the topology views

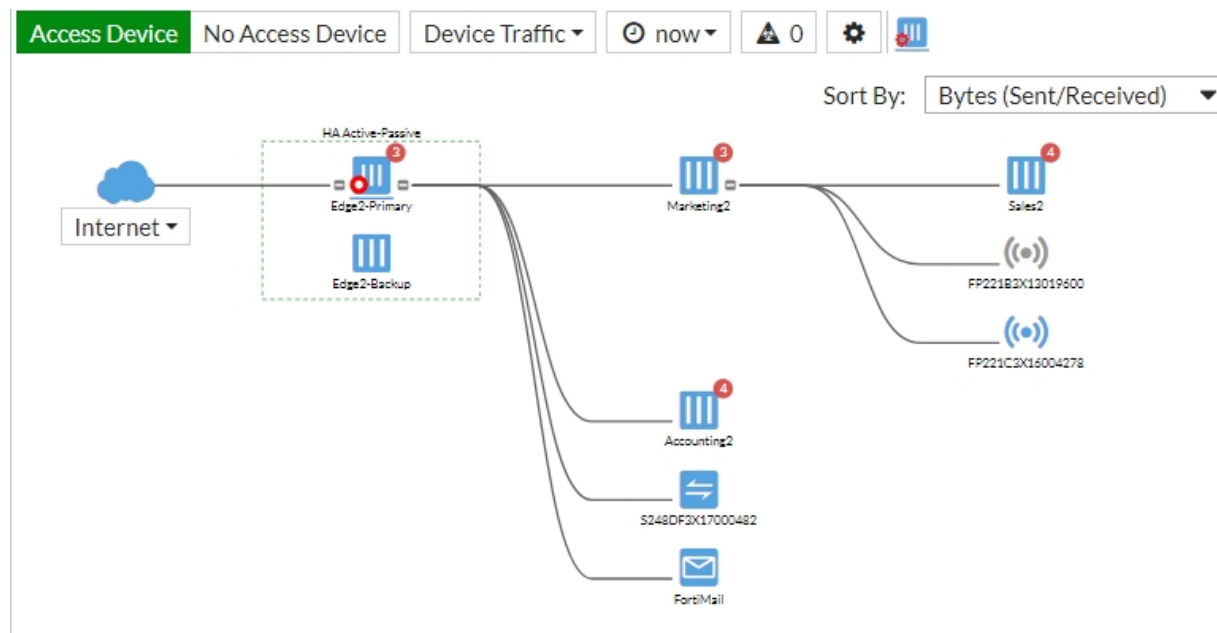

To view compromised hosts on your network and identify threats based on severity, you can click the Compromised Hosts icon in the Physical and Logical Topology views. To filter the compromised hosts by **Device Traffic**, **Device Count** or **IOC Score**, you must set the Bubble Option, located in the top-right corner. The host bubbles show different colors based on the IOC severity level. Confirmed threats appear in an actionable top-down list, located on the right side of the GUI, arranged based on threat severity.

The FortiAnalyzer in the Security Fabric retrieves the detected Indicators of Compromise (IOCs) from FortiGuard services. You can also view compromised host information in the FortiAnalyzer, in **FortiView > Threats > Compromised Hosts**.

View the Physical Topology

The Physical Topology view shows the devices in the Security Fabric and the devices they are connected to. You can also select whether or not to view access layer devices in this topology.

To see the Physical Topology, in the root FortiGate GUI, select **Security Fabric > Physical Topology**.

The Physical Topology view displays your network as a bubble chart of interconnected devices. These devices are grouped based on the upstream device they are connected to. The bubbles appear smaller or larger, based on their traffic volume. You can double-click any bubble to resize it and view more information about the device.

FortiGate devices and other networking devices are depicted as boxes. You can hover over the icon for each FortiGate to see information, such as serial number, hostname, and firmware version. You can hover over the bubbles of other devices to see information about them, such as name, IP address, and traffic volume data.

You can click the **Compromised Hosts** icon , to view compromised hosts on your network and identify threats based on severity.

Security Fabric Rating recommendations are also shown in the topology, beside the icon of the device the recommendations apply to.

View the Logical Topology

The Logical Topology view is similar to the Physical Topology view, but it shows the network interfaces, logical or physical, that are used to connect devices in the Security Fabric.

To see the Logical Topology, in the root FortiGate GUI, select **Security Fabric > Logical Topology**.

The Logical Topology view displays your network as a bubble chart of network connection points. These devices are grouped based on the upstream device interface they are connected to. The bubbles appear smaller or larger, based on their traffic volume. You can double-click any bubble to re-size it.

FortiGate devices and other networking devices are depicted as boxes. You can hover over the icon for each FortiGate to see information, such as serial number, hostname, and firmware version. You can also see each FortiGate interface that has upstream and downstream devices connected to it. You can hover over the name of an interface to see its IP address, network (subnet), and role.

You can click the **Compromised Hosts** icon , to view compromised hosts on your network and identify threats based on severity

Security Fabric Rating recommendations are also shown in the topology, beside the icon of the device the recommendations apply to.

Filter the topology views by specific criteria

You can use filters to narrow down the data on the topology views, so you can find specific information.

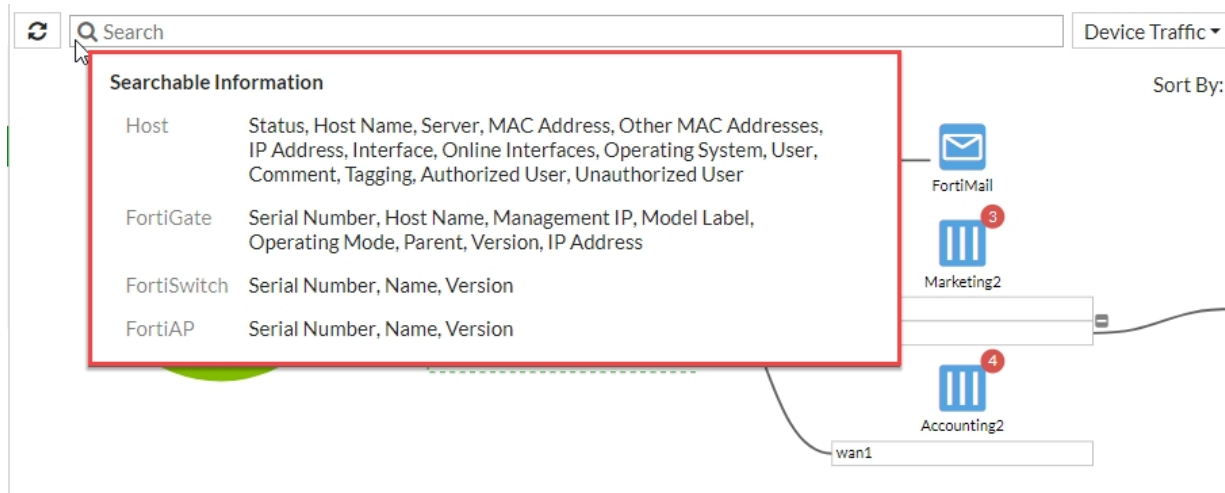

1. In the drop-down menu to the right of the **Search** field, select one of the following:
 - Device Traffic
 - Device Count
 - Device Type
 - Vulnerability
 - Threat Score
 - IOC Score
 - No Device
2. To filter the view by time, in the time period drop-down menu, select one of the following:
 - now
 - 5 minutes
 - 1 hour
 - 24 hours
 - 7 days
3. To sort the topology by traffic options, in the **Sort By** drop-down menu, select one of the following:
 - Bytes (Sent/Received)
 - Packets (Sent/Received)

- Bandwidth
- Session

Using the Search bar to find information in the topology views

The search bar, located above the Physical and Logical Topology views, can help you easily find what you're looking for in the network topology and quickly resolve security issues. For example, you can search for unauthorized hosts and then decide which devices to authorize or remove from your network. The search highlights devices that match your search criteria, and grays out devices that don't match.

To see a list of items that you can search for, mouse over the search bar and a tooltip appears that shows **Searchable Information** list, organized by host and by Fortinet device type. The following image shows the search bar and the **Searchable Information** list:

For hosts, you can search for host information, such as status, host name, and server.

For FortiGate, you can search for device information, such as serial number, host name, and management IP address.

For FortiSwitch and FortiAP, you can search for device information, such as serial number, name and OS version.

Running a Security Fabric Rating

You can run a Security Fabric Rating to analyze your organization's Security Fabric deployment, identify potential vulnerabilities, and highlight best practices that you can use to improve the overall security and performance of your organization's network.

The Security Fabric Rating performs a variety of checks when it analyzes your network. All checks are based on your current network configuration, using real-time monitoring. The check runs across all FortiGate devices in the Security Fabric.

When the check is complete, a list of recommendations is shown. Two views are available: Failed or All Results. You can filter these views further in order to view results from a specific FortiGate or all FortiGate devices. Each view has a chart that shows the results of individual checks, and includes the name and a description of the check, which FortiGate the check was performed on, the impact of the check on the overall security score, and recommendations. If you hover over the result for a check, you can see a breakdown of how the score was determined.

You can choose to automatically apply the recommendations that include the Easy Apply option. By using Easy Apply, you can change the configuration of any FortiGate in the Security Fabric. Further action is required if you want to follow other recommendations.

You can also view recommendations for specific devices in the Physical and Logical Topology views in the Security Fabric menu. If a recommendation is available for a device, a circle containing a number appears. The number shows how many recommendations are available. The color of the circle shows the severity of the highest check that failed. The following table shows the severity that each color represents:

Color	Severity
Red	Critical
Orange	High
Yellow	Medium
Blue	Low

For more information about the Security Fabric Rating, and details about each of the checks that are performed, see the [Fortinet Recommended Security Best Practices](#) document.

Run a Security Fabric check

You must run the Security Fabric Rating check on the root FortiGate in the Security Fabric.

The following image shows the GUI:

Security Rating

Issue	FortiGate	Result	Recommendation
Fabric Security Hardening	4	40	
Firmware & Subscriptions	1		
Network Design & Policies	4		
Threat and Vulnerability Management	3		

Easy Apply >

1. In the root FortiGate GUI, select **Security Fabric > Security Rating**. Click **Show Topology** to view all FortiGate devices in the Security Fabric.
2. To run the check, select **Run Now**.
The check will run. When it completes, it shows the following information:
 - The **Security Rating Score** field shows the score for your Security Fabric
 - The page shows the overall count of how many checks passed or failed, with the failed checks divided by severity
 - Information about each failed check, including which FortiGate failed the check, the effect of the check failure on the security score, and recommendations to fix the issue
 - The **Easy Apply** option appears with recommendations that can be automatically applied by the wizard
3. To move to the **Easy Apply** option page, select **Next**.
4. Select all recommendations that you want to implement in the Security Fabric.
5. Select **Apply Recommendations**.

Not all FortiGate models can run the FortiGuard Security Rating Service if they are the root FortiGate in a Security Fabric. For more information, see the [FortiOS 6.0 Release Notes](#).

Security Fabric Rating license

The Security Rating license is a FortiGuard service and you must purchase a license to access to all the latest features. Security audit checks from FortiOS 5.6 will continue to run, but the following new upgrades are available only when you purchase a Security Rating license:

- Receive FortiGuard updates.
- Run Security Rating checks across each licensed device or all FortiGates in the Security Fabric from the Root FortiGate.
- New 6.0 Rating checks
- Submit rating scores to FortiGuard and receive Security Rating scores from FortiGuard for ranking customers by percentile.

For more information, see the [Fortinet Recommended Security Best Practices](#) document.

Opt out of customer ranking service

You can opt out of submitting Security Rating scores to FortiGuard.

If you opt out of from submitting your network's Security Rating scores, you won't be able to see how your organization's scores compare with the scores of other organizations. Instead, an absolute score is shown.

To disable FortiGuard Security Rating result submission - CLI:

```
config system global
    set fortiguard-audit-result-submission disable
end
```

Logging for Security Fabric Rating

To view the results of past Security Fabric Rating checks, go to **Log & Report > Security Rating Events**.

You can also configure an event filter subtype for the Security Fabric Rating. When you run a check, event logs are created on the root FortiGate that summarize the results of the audit and show detailed information for the individual tests.

To configure logging for the Security Fabric Rating, use the following CLI commands:

```
config log eventfilter
    set security-audit enable
end
```

Understanding the Security Fabric Score

When you run a Security Fabric Rating, your organization's Security Fabric receives a Security Fabric Score. The score will be positive or negative, and a higher score represents a more secure network.

The score is based on how many checks your network passes and fails, as well as the severity level of these checks. The following table shows the weight for each severity level:

Severity level	Weight
Critical	50 points
High	25 points
Medium	10 points
Low	5 points

The check awards points when a check passes, using the following formula:

$$+ <Severity Weight> \times <Secure FortiGate Multiplier>$$

where:

- *Severity Weight* is $<Severity level> / <number of FortiGate devices in the Security Fabric>$
- *Secure FortiGate Multiplier* is determined using logarithms and the number of FortiGate devices in the Security Fabric

For example, if you have four FortiGate devices in the Security Fabric, and all of them pass the Compatible Firmware check, the score for each FortiGate is calculated as: $(50/4) \times 1.292 = 16.2$ points.

All FortiGate devices in the Security Fabric must pass the check in order to receive points. If any of the FortiGate devices in the Security Fabric fail a check, any FortiGate devices in the Security Fabric that passed the check are not awarded points. For the FortiGate that failed the test, the score is calculated using the following formula:

$$- <Severity Weight> \times <Count>$$

where:

- *Severity Weight* is $<Severity level>$
- *Count* is the number of times the check failed during the check

For example, if the check finds two critical FortiClient vulnerabilities, the score for that check is calculated as: $-50 \times 2 = -100$ points.

The score is not affected by checks that do not apply to your network. For example, if you do not have any FortiAP devices in the Security Fabric, you will not receive any points for the FortiAP Firmware Versions check.

Automation stitches

Automation stitches can be used for FortiGate devices that are not part of a Security Fabric.

Automation stitches allow you to decrease response times to security events by automating the activities between different device components in the Security Fabric. You can monitor events from any source in the Security Fabric and set up action responses to any destination.

This section includes:

- [Trigger events](#)
- [Response actions](#)
- [Creating automation stitches](#)
- [Configuring an automation, trigger, and action in the CLI](#)
- [Chaining and delaying actions for AWS Lambda and webhook](#)
- [Diagnose commands for automation stitches](#)

Trigger events

You can configure FortiOS to automatically respond to the following trigger events: IOC, event log, reboot, conserve mode, high CPU, license expiry, HA failover, and configuration changes. The following table provides more information about the trigger event list.

Icon	Trigger	Description
	Compromised Host	<p>An Indicator of compromise (IOC) is detected on a host endpoint.</p> <p>If you configure a Compromised Host trigger you also need to set the IOC level threshold to Medium or High. If you set this to Medium, both medium and high threshold attacks trigger an action.</p> <p>The additional Action options are the following: Access Layer Quarantine, Quarantine FortiClient via EMS, and IP Ban.</p>

Icon	Trigger	Description
	Security Rating Summary	A summary is available for a recently run Security Rating.
	Configuration Change	There is a FortiGate configuration change.
	Reboot	A FortiGate reboot occurs.
	License Expiry	<p>A FortiGuard license is expiring.</p> <p>You must select which type of license you want to be notified about if it expires: FortiCare Support, FortiGuard Web Filter, FortiGuard AntiSpam, FortiGuard AntiVirus, FortiGuard IPS, FortiGuard Management Service, and FortiCloud.</p>
	HA Failover	HA failover occurs.
	AV & IPS DB Update	The antivirus and IPS database updates.

Icon	Trigger	Description
	Event Log	A FortiGate log with a specific event ID occurs. If you configure an Event Log trigger you'll also need to enter a Log ID .
CLI only	Conserve Mode	A FortiGate enters conserve mode due to low memory.
CLI only	High CPU	A FortiGate has high CPU usage.

Response actions

There are four main types of alert notifications you can set up to respond to an event trigger: **Email**, **FortiExplorer Notification**, **AWS Lambda**, and **Webhook**. There are also additional response actions for the Compromised Host (IOC): **Access Layer Quarantine**, **Quarantine FortiClient via EMS** and **IP ban**.

It's recommended that you set a **Minimum Interval** for each action. For more information, see ["Avoiding repeat event notifications" on page 2353](#).

Main Alert Notification Actions

Icon	Action	Description
	Email	Use this action to send a custom email notification. You must enter an email address and subject line.
	FortiExplorer Notification	Use this action to send push notifications to FortiExplorer. For the push to be successful, the FortiGate must be registered with FortiExplorer app on the iOS device you want to receive notifications on.

Icon	Action	Description
	AWS Lambda	<p>Use this action to invoke Amazon Web Services (AWS) Lambda.</p> <p>For the API Gateway endpoint, you can manually enter the URL or you can enter the Parameters individually.</p> <p>For URL, you must enter the following variables:</p> <ul style="list-style-type: none"> • Enter the URL. For example, "1a2b3c.execute-api.us-east-1.amazonaws.com/stagename/notification" • For API Key, enter the same API Key that you use for your AWS API Gateway. <p>For Parameters, you must enter the following variables:</p> <ul style="list-style-type: none"> • Set the Region. For example, "us-east-1" • Set the ID to the REST API ID. For example, "1a2b3c" • Set the Path to the resource you configured in your API Gateway. For example, "notification". • Set the Stage to the stage name from your AWS API Gateway. For example, "stagename". • For the API Key, enter the same API key that you configured in your AWS API Gateway.
	Webhook	<p>Use this action to send data to another application using a REST callback.</p> <p>You must enter the following:</p> <ul style="list-style-type: none"> • For Protocol select HTTP or HTTPS. • For Method select POST, PUT, or GET. • Enter the URI. For example, "website.com/notifications" • Set the Port. • For HTTP Body enter the text you want (up to 1023 characters). For example, {"trigger": "reboot"}. • For HTTP Header, enter the Name and Value you want. For example, "x-notification-source" and "Fortinet".

Additional Compromised Host response actions

Icon	Action	Description
	Access Layer Quarantine	Use this action to impose a dynamic quarantine on multiple endpoints based on the access layer.

Icon	Action	Description
	Quarantine FortiClient via EMS	<p>Use this action to use FortiClient EMS to block all traffic from the source addresses flagged as compromised hosts. Quarantined devices are flagged on the Security Fabric Physical and Logical topology views.</p> <p>Go to Monitor > Quarantine Monitor to view quarantined IP addresses. Addresses are automatically removed from the quarantine after a configurable period of time.</p>
	IP Ban	<p>Use this action to block all traffic from the source addresses flagged by the IOC.</p> <p>Go to Monitor > Quarantine Monitor to view banned IP addresses. Banned IP addresses can only be removed from the list by administrator intervention.</p>

Avoiding repeat event notifications

The **Minimum interval** establishes the amount of time, in seconds, before you receive a repeat alert notification about the same event. This helps avoid receiving multiple alerts on your phone every few minutes for the same offense. When the interval has elapsed, a collated report detailing the activities during that time frame will be sent.

For example, if you were configuring an alert for high CPU usage, and you set the Minimum interval to 86400s (1 day) then you receive one alert when the CPU usage went above 90% and you would not get another alert notification for the same event until the next day. When the 86400s (1 day) elapses, you receive a notification with a summary that let's you know how many times the CPU usage exceeded 90% in the past day.

Creating automation stitches

To create an automation, you can set up a trigger event and response actions that cause the FortiOS to respond in a predetermined way. From the root FortiGate, you can set up triggers for event types, such as compromised host, high CPU, and configuration changes. The automation launches actions in response, such as email alerts, FortiExplorer notifications, and webhooks. The **Compromised Host** trigger has additional actions, such as access layer quarantine and quarantine FortiClient via EMS.

To create and test an automation - GUI:

1. Log in to the root FortiGate, and go to **Security Fabric > Automation**. Select **Create New**.
2. Customize the stitch by selecting a **Trigger** event type and the corresponding **Action** that you would like to automate. You can configure multiple actions for the same event trigger.

Enter the following information:

Name	Enter a name for the new automation.
-------------	--------------------------------------

Status	Select Enabled to enable this automation.
FortiGate	From the drop-down menu, select the FortiGate device to apply this automation to or select All FortiGates (default) to apply to all.
Trigger	<p>Select a Trigger from the following event types:</p> <ul style="list-style-type: none"> • Compromised Host <ul style="list-style-type: none"> • Set IOC level threshold to Medium or High. • Event Log <ul style="list-style-type: none"> • Enter a Log ID. • Reboot • Conserve Mode • High CPU • License Expiry <ul style="list-style-type: none"> • Set the Licensetype to one of the following: FortiCare Support, FortiGuard Web Filter, FortiGuard AntiSpam, FortiGuard AntiVirus, FortiGuard IPS, FortiGuard Management Service, or FortiCloud. • HA Failover • Configuration Changes
Action	<p>If the Trigger event you select occurs, an alert is sent using the methods that you select here. Select at least one of the following Action types:</p> <ul style="list-style-type: none"> • Email <ul style="list-style-type: none"> • Email subject: Enter an email subject. • To: Enter at least one email address. Select the plus + icon to add additional email addresses. • FortiExplorer Notification • AWS Lambda • Webhook <p>NOTE: When you set the trigger to Compromised Host, the following Actions are available:</p> <ul style="list-style-type: none"> • Access Layer Quarantine • Quarantine FortiClient via EMS • IP Ban
Minimum interval (seconds)	Enter a minimum time interval, in seconds, during which you won't receive repeated notifications for the same trigger occurrence. When the minimum time interval expires, you'll receive an alert with a compilation report of any events that occurred during the allotted interval period.

3. Select **OK**.
4. To test the new automation, right-click it and select **Test Automation Stitch**.

When an automation stitch is triggered, the FortiGate creates an event log, which you can view by going to **Log & Report > System Events**.

To create and test an automation - CLI:

```
config system automation-stitch
  edit <automation-stitch-name>
    set status {enable | disable}
    set trigger <trigger-name>
    set action <action-name>
    set destination <serial-number>
  next
end

diagnose automation test <automation-stitch-name> <log>
```

You can configure an automation using the `config system automation-stitch` command shown above. For more information about configuring the **Trigger**<trigger-name> and **Action**<action-name> components, see: ["Configuring an automation, trigger, and action in the CLI" on page 2355](#).

Configuring an automation, trigger, and action in the CLI

This section provides instructions for how to create an automation, and expands on the CLI syntax shown in the introduction by explaining further details, including how to create both a trigger and an action.

To enable the Security Fabric - CLI:

```
config system csf
  set status enable
end
```

To create an "automation-stitch" - CLI:

```
config system automation-stitch
  edit <Automation-stitch-name>
    set status {enable | disable}
    set trigger <trigger-name>
    set action <action-name>
    set destination <serial-number>
  next
end
```

Where the following variables are set:

Variable	Description	Default
<code>edit <Automation-stitch-name></code>	Enter the name of the new automation.	No default

Variable	Description	Default
<code>set status {enable disable}</code>	Enter <code>enable</code> to enable the stitch.	Enable
<code>set trigger <trigger-name></code>	Enter a trigger.	No default
<code>set action <action-name></code>	Enter at least one action you want to occur when a trigger event or schedule occurs.	No default
<code>set destination <serial-number></code>	The <code>destination</code> can be set to a list of device serial numbers, separated by spaces or left blank to use all members of the Security Fabric. Automation stitches are only applied to serial numbers listed in the destination.	All FortiGates

To create an "automation-action" - CLI:

```

config system automation-action
  edit <action-name>
    set action-type {email | ios-notification | alert | disable-ssid | quarantine |
      quarantine-forticlient | ban-ip | aws-lambda | webhook}
    set email-to <email-address>
    set email-subject <subject-name>
    set minimum-interval <seconds>
  next
end

```

Where the following variables are set:

Variable	Description	Default
<code>edit <Automation-action-name></code>	Enter the name of the new automation action.	No default
<code>set action-type</code>	Select an action type from the following: email, ios-notification, alert, disable-ssid, quarantine, quarantine FortiClient, ban IP, AWS Lambda, and webhook.	No default
<code>set email-to <email-address></code>	Enter the email address from which you would like to receive alert notifications. You can add multiple emails by selecting the + icon.	No default
<code>set email-subject <subject-name></code>	Enter the email subject which you would like to see on your email notification alerts.	No default
<code>set minimum-interval</code>	Enter a minimal time interval between 0 to 2592000 seconds, during which a repeat offense of an action will be ignored to help avoid repeat alerts.	Default = 0 seconds

To create an "automation-trigger" - CLI:

```

config system automation-trigger
  edit <trigger-name>
    set trigger-type {event-based | scheduled}
    set event-type {ioc | event-log | reboot | low-memory | high-cpu | license-near-
      expiry | ha-failover | config-change}
    set ioc-level {medium | high}
    set logid [1-99999]
    set license-type {forticare-support | fortiguard-webfilter | fortiguard-antispam
      | fortiguard-antivirus | fortiguard-ips | fortiguard-management | forticloud
      | set trigger-frequency}
    set trigger-frequency {hourly | daily | weekly | monthly}
    set trigger-day <1-31>
    set trigger-hour <0-23>
    set trigger-minute <0-60>
  next
end

```

Where the following variables are set:

Variable	Description	Default
edit <automation-trigger-name>	Enter the name of the new trigger.	No default
set event-type	Select the event type from the following: <ul style="list-style-type: none"> • ioc • event-log • reboot • low-memory • high-cpu • license-near-expiry • ha-failover • config-change 	No default
set ioc-level	Set the IOC level to medium or high. Where: <ul style="list-style-type: none"> • medium sends alerts for both medium and high IOC levels. • high only sends alerts for high IOC levels. NOTE: Only available when event-type is set to ioc.	No default
set logid	Log ID to trigger event. Value from NOTE: Only available when event-type is set to event-log.	No default

Variable	Description	Default
<code>set license-type</code>	<p>Select the license type that you would like to be notified of in the event of expiry. The options include:</p> <ul style="list-style-type: none"> • <code>forticare-support</code> (FortiCare support license) • <code>fortiguard-webfilter</code> (FortiGuard web filter license) • <code>fortiguard-antispam</code> (FortiGuard antispam license) • <code>fortiguard-antivirus</code> (FortiGuard AntiVirus license) • <code>fortiguard-ips</code> (FortiGuard IPS license) • <code>fortiguard-management</code> (FortiGuard management service license) • <code>forticloud</code> (FortiCloud license) <p>NOTE: Only available when <code>event-type</code> is set to <code>license-near-expiry</code>.</p>	No default
<code>set trigger-type</code>	Enter the trigger type as either <code>event-based</code> or <code>scheduled</code> .	No default
<code>set trigger-frequency</code>	<p>How often the trigger is run.</p> <p>The options for the scheduled trigger frequency are the following: hourly, daily, weekly, or monthly.</p> <p>NOTE: Only available when <code>trigger-type</code> is set to <code>scheduled</code>.</p>	Daily.
<code>set trigger-day</code>	Enter an integer value from 1 to 31. This is the day within the month to trigger.	No default
<code>set trigger-hour</code>	<p>Enter the hour of the day on which to trigger from 0 to 23.</p> <p>NOTE: Only available when <code>trigger-type</code> is set to <code>scheduled</code>.</p>	1
<code>set trigger-minute</code>	Enter the minute of the hour on which to trigger (0 - 59, 60 to randomize).	No default

Setting up an automation destination

The `config system automation-destination` command allows you to set the type to the primary FortiGate of an HA cluster or a single FortiGate, and both types of endpoint require it to be set to a destination [by serial number]. Then you can add the destination to any automation stitch. For more information on how to configure an HA cluster as the automation destination see the *High Availability Handbook*.

To set an automation destination:

```
config system automation-destination
  edit <name>
    set type {fortigate | ha-cluster}
    set destination <serial_number>
    set ha-group-id <number>
  next
```

Then you can add the destination to any automation stitch:

```
config system automation-stitch
  edit <stitch-name>
    set destination <destination-name>
  end
```

Chaining and delaying actions for AWS Lambda and webhook

For automation stitches that use the action for **AWS Lambda** or **Webhook**, extra options are available to support chaining and delaying these actions. You can configure these options using the CLI.

To enable chaining actions by delaying an action until the previous action is finished, use the command `set required enable`. This option is only available when `action-type` is set to `aws-lambda` or `webhook`, and it's disabled by default.

To delay the execution of the action, use the command `set delay <seconds>`. This option is only available when `action-type` is set to `aws-lambda` or `webhook`, and it's set to 0 by default.

CLI syntax

```
config system automation-action
  edit <name>
    set action-type {aws-lambda | webhook}
    set required {enable | disable}
    set delay <seconds>
  next
end
```

Diagnose commands for automation stitches

Diagnose commands are available for automation stitches, allowing you to do the following:

- [Test an automation stitch](#)
- [Enable and disable log dumping for automation stitches](#)
- [Display settings for every automation stitch](#)
- [Display history for every automation stitch](#)

Test an automation stitch

To test an automation stitch, use the `diagnose automation test <automation-stitch-name> <log>` command.

Example output

```
# diagnose automation test HA-failover
automation test is done. stitch:HA-failover
```

Enable and disable log dumping for automation stitches

To toggle between enabling and disabling log dumping, use the `diagnose test application autod 1` command.

Example output

```
# diagnose test application autod 1
autod log dumping is enabled

# diagnose test application autod 1
autod log dumping is disabled

autod logs dumping summary:
autod dumped total:0 logs, num of logids:0
```

Display settings for every automation stitch

To display settings for all automation stitches, use the `diagnose test application autod 2` command.

Example output

```
# diagnose test application autod 2
csf: enabled root:yes
total stitches activated: 2

stitch: Compromised-IP-Banned
destinations: all
trigger: Compromised-IP-Banned
actions:
Compromised-IP-Banned_ban-ip type:ban-ip interval:0

stitch: HA-failover
destinations: HA-failover_ha-cluster_25;
trigger: HA-failover
actions:
HA-failover_email type:email interval:0
subject: HA Failover
mailto:admin@example.com;
```

Display history for every automation stitch

To display the history for all your automation stitches, use the `diagnose test application autod 3` command.

Example output

```
# diagnose test application autod 3

stitch: Compromised-IP-Banned

local hit: 0 relayed to: 0 relayed from: 0
last trigger:Wed Dec 31 20:00:00 1969
last relay:Wed Dec 31 20:00:00 1969

actions:
Compromised-IP-Banned_ban-ip:
done: 0 relayed to: 0 relayed from: 0
last trigger:Wed Dec 31 20:00:00 1969
last relay:Wed Dec 31 20:00:00 1969

stitch: HA-failover

local hit: 1 relayed to: 1 relayed from: 1
last trigger:Thu May 24 11:35:22 2018
last relay:Thu May 24 11:35:22 2018

actions:
HA-failover_email:
done: 1 relayed to: 1 relayed from: 1
last trigger:Thu May 24 11:35:22 2018
last relay:Thu May 24 11:35:22 2018
```

Fabric Connectors

You can use Fabric Connectors for FortiGate devices that don't belong to a Security Fabric.

There are three types of Fabric Connectors, which allow you to connect your network to external services. The three types are: SDN, SSO/identity, and threat feeds.

This section contains the following information:

- [Available services for Fabric Connectors](#)
- [Configuring Fabric Connectors](#)
- [Verifying Fabric Connector status](#)
- [Fabric Connector resources](#)

Available services for Fabric Connectors

Fabric Connectors support the following services:

SDN connectors

- Amazon Web Services
- Cisco Application Centric Infrastructure
- Google Cloud Platform
- Microsoft Azure
- Nuage Virtualized Services Platform
- Oracle Cloud Infrastructure
- VMware NSX

SSO/identity connectors

- Poll Active Directory server
- RADIUS single sign-on agent
- Fortinet single sign-on agent

Threat feed connectors

- FortiGuard category
- Firewall IP address
- Domain name

If your FortiGate has VDOMs enabled, SDN and threat feed connectors are global settings, while SSO/identity connectors are available per-VDOM.

Configuring Fabric Connectors

The method that you use to configure a Fabric Connector depends on which type of connector you're using:

- [Creating an SDN Connector](#)
- [Creating an SSO Connector](#)
- [Creating a Threat Feed Connector](#)

Creating an SDN Connector

FortiOS doesn't support multiple SDN Connector instances to Amazon Web Services, Google Cloud Platform, Microsoft Azure, and VMware NSX.

Software-Defined Network (SDN) Connectors provide integration and orchestration of Fortinet products with key SDN solutions. You use SDN Connectors to make sure that any changes in your SDN environment are automatically updated in your network.

To create an SDN Connector, you need to do the following:

- [Gather required information](#)
- [Create the Fabric Connector](#)
- [Create a Fabric Connector address](#)
- [Add the address to a firewall policy](#)

For an example of how to configure a Fabric Connector for Microsoft Azure, see [FortiGate SDN Connector for Azure](#).

Gather required information

Before you can create an SDN Connector, you need to know specific information, which differs depending on which service you're using. You can find this information using your account for the specific service.

Service	Required information for the service
Amazon Web Services	<ul style="list-style-type: none">• Access key ID• Secret access key• Region name• VPC ID (optional)
Cisco Application Centric Infrastructure	<ul style="list-style-type: none">• IP address• Port• Username• Password

Service	Required information for the service
Google Cloud Platform	<ul style="list-style-type: none">• Project name• Service account email• Private key
Microsoft Azure	<ul style="list-style-type: none">• Tenant ID• Client ID• Client secret• Subscription ID (optional)• Resource group (optional)
Nuage Virtualized Services Platform	<ul style="list-style-type: none">• IP address• Port• Username• Password
Oracle Cloud Infrastructure	<ul style="list-style-type: none">• User ID• Tenant ID• Compartment ID• Server region• Certificate
VMware NSX	<ul style="list-style-type: none">• IP address or hostname• Username• Password

Create the Fabric Connector

You can create the Fabric Connector using either the GUI or CLI. The CLI commands that are available vary depending on which service you're using.

Creating a Fabric Connector - GUI:

1. To create a new connector, go to **Security Fabric > Fabric Connectors** and select **Create New**.
2. Select the service you're using and enter the required information for that service.
3. Select **OK**.

Creating a Fabric Connector - CLI:

To create a Fabric Connector using the CLI, use the command `config system sdn-connector`. For more information about this command, see the [FortiOS 6.0 CLI Reference](#).

Create a Fabric Connector address

You use a Fabric Connector address for the following:

- As the source or destination address for firewall policies
- To automatically update changes to the addresses in the environment of the service you're using, based on specified filtering conditions
- To automatically apply changes to the firewall policies that use the address, based on specified filtering conditions

Creating a Fabric Connector address - GUI:

1. To create a new address, go to **Policy & Objects > Addresses** and select **Create New > Address**.
2. Set a **Name** for the address.
3. Set **Type** to **Fabric Connector Address** and set **Fabric Connector Type** to the appropriate service.
4. Set a **Filter**. This filter dynamically creates the members of the address. The types of filters that are supported vary depending on which service you're using.
5. Set a specific **Interface** or leave it as the default **any**.
6. Select **OK**.

Creating a Fabric Connector address - CLI:

```
config firewall address
  edit <name>
    set type dynamic
    set comment <comment>
    set visibility enable
    set associated-interface <interface_name>
    set sdn {aci | aws | azure | nsx | nuage | oci}
    set filter <filter>
  next
end
```

Add the address to a firewall policy

You use a Fabric Connector addresses in a firewall policy as either the source or destination address.

Adding the address to a policy - GUI:

1. To create a new policy, go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Set a **Name** for the policy.
3. Set the appropriate **Incoming Interface** and **Outgoing Interface**.
4. Set the Fabric Connector address as either the **Source** or **Destination** address, as appropriate.
5. Set other policy settings, as required.
6. Select **OK**.

Adding the address to a policy - CLI:

```
config firewall policy
  edit 0
    set name <name>
    set srcintf <port_name>
    set dstintf <port_name>
    set srcaddr <firewall_address>
    set dstaddr <firewall_address>
    set action accept
    set schedule <schedule>
```

```
    set service <service>
  next
end
```

Creating an SSO Connector

SSO Connectors integrate single sign-on (SSO) authentication in your network. SSO allows users to enter their credentials once and have those credentials reused when they access other network resources through your FortiGate.

Connectors are available for the following services:

- Poll Active Directory (AD) server
- RADIUS Single Sign-On (RSSO) agent
- Fortinet Single Sign-On (FSSO) agent

For more information about SSO Connectors, see the [Chapter 3 - Authentication](#).

Creating a Threat Feed Connector

Threat Feed Connectors dynamically import an external block list, in the form of a text file containing a list of either addresses or domains, which resides on an HTTP server. You use block lists to deny access to source or destination IP addresses in web filter and DNS filter profiles, SSL inspection exemptions, and as sources or destinations in proxy policies.

You can configure the following types of threat feeds:

- FortiGuard category
- IP address
- Domain name

For more information about Threat Feed Connectors, see "Overriding FortiGuard website categorization" on page 2455.

Verifying Fabric Connector status

You can only verify the status for Fabric Connectors to AWS, Microsoft Azure, OCI, and VMware NSX.

To verify the status of a Fabric Connector, use one of the following commands:

- `diagnose system sdn status` to verify all connectors
- `diagnose system sdn status <connector_name>` to verify a specific connector

After you enter the command, one of four statuses is displayed:

- `connected`: the connector is connected
- `not connected`: the connector isn't connected
- `disabled`: the related connector entry is set to disabled
- `unknown`: verification of the connector isn't supported

Example output

```
# diagnose sys sdn status
SDN Connector Type Status
-----
aci-sdn-connector aci unknown
aws-sdn-connector aws disabled
azure-sdn-connector azure not connected
nsx-sdn-connector nsx connected
```

Central management with FortiManager

This section describes the basics of using FortiManager as an administration tool for multiple FortiGate devices. It describes the key management features you can use to manage a FortiGate in FortiManager. It contains the following sections:

- [Configuring the FortiManager](#)
- [FortiGuard](#)
- [Firmware updates](#)
- [Administrative domains](#)
- [Backing up and restoring configurations](#)
- [FortiManager in backup mode](#)

For more information about FortiManager, see the [FortiManager Administration Guide](#).

For the FortiGate and the FortiManager to connect properly, both devices must have compatible firmware. To find out if your firmware is compatible, see the [FortiOS Release Notes](#) and [FortiManager Release Notes](#).

Configuring the FortiManager

For information about configuring the connection between your FortiGate devices and FortiManager, see ["Adding a FortiManager to the Security Fabric" on page 2334](#).

After you configure the connection between your FortiGate devices and FortiManager, you can configure the following items on the FortiManager:

- [Configuring updates through FortiManager](#)
- [Using global objects](#)
- [Locking the FortiGate GUI](#)
- [SSL connections](#)

Configuring updates through FortiManager

With the FortiManager system, you can monitor and configure multiple FortiGate devices from one location. You can use the FortiManager Device Manager to view FortiGate devices and make the usual configuration updates and changes, without logging in and out of multiple FortiGate devices.

FortiManager allows you to complete the configuration by going to the Device Manager, selecting the FortiGate, and using the same menu structure and pages as you see in the FortiGate GUI. All changes to the FortiGate configuration are stored locally on the FortiManager until you synchronize with the FortiGate.

When a FortiGate is under the control of a FortiManager device, you shouldn't use the FortiGate to change the configuration. When you try to change options, the FortiGate displays a message stating that it's configured through FortiManager and any changes may be reverted.

Central management configuration supports multiple FortiManager addresses, which helps mainly in the case where the FortiGate is behind NAT.

Using global objects

If you maintain several FortiGate devices within a network, many of the policies and configuration elements are the same across your organization. You can use FortiManager global objects to simplify policy configuration for the FortiGate devices in the network so that you don't have to add and edit many of the same policies on each FortiGate device.

A global object is an object that isn't associated with one device or group. Global objects include security policies, a DNS server, VPNs, and IP pools. You can copy the configurations to the FortiManager device database for a selected device or group of devices. You can also import configurations from the FortiManager device database for a selected device and modify the configuration, as required. When you configure or create a global policy object, the interface, prompts, and fields are the same as creating the same object on a FortiGate using the FortiGate GUI.

Locking the FortiGate GUI

When you use the FortiManager to manage multiple FortiGate devices, a local FortiGate is locked and most administrators are prevented from making configuration changes, using the GUI. The `super_admin` can still make changes to the configuration, but this isn't recommended since it may cause conflicts with the FortiManager.

SSL connections

An SSL connection can be configured to encrypt traffic between FortiManager and the FortiGate devices.

Configuring an SSL connection

Use the following CLI commands in the FortiGate CLI to configure the connection:

```
config system central-management
  set status enable
  set enc-algorithm {default* | high | low}
end
```

The default encryption automatically sets high and medium encryption algorithms. Algorithms used for high, medium, and low follows openssl definitions:

- **High** - Key lengths larger than 128 bits, and some cipher suites with 128-bit keys.

Algorithms are: DHE-RSA-AES256-SHA:AES256-SHA: EDH-RSA-DES-CBC3-SHA: DES-CBC3-SHA:DES-CBC3-MD5:DHE-RSA-AES128-SHA:AES128-SHA

- **Medium** - Key strengths of 128 bit encryption.

Algorithms are: RC4-SHA:RC4-MD5:RC4-MD

- **Low** - Key strengths of 64 or 56 bit encryption algorithms but excluding export cipher suites

Algorithms are: EDH-RSA-DES-CBC-SHA; DES-CBC-SHA; DES-CBC-MD5.

Enable / disable logging of SSL connection events

The following commands allow the user to enable or disable logging of SSL connection events. The default is `disable`.

Syntax

```
config system global
    set log-ssl-connection {enable | disable}
end
```

Enabling or disabling static key ciphers (379616)

The following CLI commands under `system global` let you enable or disable static key ciphers in SSL/TLS connections (e.g., AES128-SHA, AES256-SHA, AES128-SHA256, AES256-SHA256). The default is `enable`.

Syntax

```
config system global
    set ssl-static-key-ciphers{enable | disable}
end
```

FortiGuard

The FortiGuard Distribution Network (FDN) provides FortiGuard services for the FortiManager system and its managed devices and FortiClient agents. The FDN is a world-wide network of FortiGuard Distribution Servers (FDS), which update the FortiGuard services on your FortiManager system on a regular basis so that your FortiManager system is protected against the latest threats.

This section contains the following:

- [Setting up FortiGuard](#)
- [Configuring FortiGuard licensing for devices with limited or no connectivity](#)
- [Troubleshooting your FortiGuard connection](#)

Setting up FortiGuard

In FortiGuard Management, you can configure the FortiManager system to act as a local FDS, or use a web proxy server to connect to the FDN. FortiManager systems acting as a local FDS synchronize their FortiGuard service update packages with the FDN, then provide these updates and look up replies to the FortiGate devices in your private network. The local FDS provides a faster connection, which reduces the Internet connection load and the time that's required to apply frequent updates, such as antivirus signatures, to many devices.

The default port that's used for FortiGuard services is UDP/8888.

The FortiManager system includes the following FortiGuard services:

- Antivirus and IPS engines and signatures (including mobile malware)
- Web filtering and email filtering rating databases and lookups (select systems)
- Vulnerability scan and management support for FortiAnalyzer

To view and configure these services, go to **FortiGuard > Settings** on the FortiManager.

FortiManager can also connect to the FortiGuard Distribution Network (FDN) to receive push updates for IPS signatures and antivirus definitions. These updates can then be used to update multiple FortiGate devices throughout your organization. By using the FortiManager as the host for updates, bandwidth use is minimized as updates are downloaded to one source instead of many.

To receive IPS and antivirus updates from FortiManager, indicate an alternate IP address on the FortiGate.

To configure updates from FortiManager - GUI:

1. In the FortiGate GUI, go to **System > FortiGuard**.
2. Under **AntiVirus & IPS Updates**, enable both **Accept push updates** and **Use override push**.
3. Enter the IP address of the FortiManager.
4. Select **Apply**.

The FortiManager can also operate as a local FDS server when it's in a closed network with no Internet connectivity. For more information, see ["Configuring FortiGuard licensing for FortiGate devices with limited or no connectivity" on page 1](#).

Extended database version OIDs for AV and IPS

New extended database version OIDs ensure accurate display of the AntiVirus and IPS databases in use when you go to **System > FortiGuard**.

IPS signatures page

The IPS signatures list page shows which IPS package is currently deployed. You can change the IPS package by hovering over the information icon next to the IPS package name. Text appears that links directly from the IPS signatures list page to the **System > FortiGuard** page on the FortiGate.

The central management FortiGuard server list can include FQDNs

This feature implements support for FQDN, to make it an option for central-management server-list.

To add FQDN as an address type - GUI:

On **System > FortiGuard > Override FortiGuard Servers > Create New / Edit**, an **FQDN** option, is added for **Address Type**.

CLI changes

```
config server-list
  edit 1
    set server-type {update | rating}
    set addr-type {ipv4 | ipv6 | fqdn} <== added fqdn
    set server-address ipv4
    set server-address6 ipv6
    set fqdn FQDN <== added
  end
end
```

Sending malware statistics to FortiGuard

To support following malware trends and making zero-day discoveries, FortiGate devices send encrypted statistics to FortiGuard about IPS, application control, and antivirus events that FortiGuard services running on

the FortiGate detect. FortiGuard uses the statistics collected to achieve a balance between performance and security effectiveness by moving inactive signatures to an extended signature database.

The statistics include some non-personal information that identifies the FortiGate and its country. This information is never shared with external parties. You can choose to disable the sharing of this information by entering the following CLI command:

```
config system global
    set fds-statistics disable
end
```

Configuring FortiGuard licensing for devices with limited or no connectivity

In some high security environments, Internet service from internal FortiGate devices or for the FortiManager is restricted. This section describes how to configure devices with limited or no internet connectivity to receive FortiGuard updates.

Preliminary steps

1. Register the FortiGate. For a physical FortiGate, use the serial number. For a FortiGate virtual machine (VM), use the registration number. To register the FortiGate, visit the [Fortinet Support](#) website.
2. For FortiGate VMs, the registration process creates a unique license file that's available under **Asset > View/Manage Products**. Select the correct device and download the license file.

This section assumes that:

- Internal FortiGate devices can access a local physical FortiManager or FortiManager VM.
- The FortiManager is running firmware version 6.0.0 or later.

After you have completed the following steps, use the following instructions:

- [Configuring a FortiGate without Internet connectivity to access a local FortiManager as FDN](#)
- [Configure FortiManager without Internet connectivity as a local FDN server](#)

Configuring a FortiGate without Internet connectivity to access a local FortiManager as FDN

By default, FortiGate connects to the public FDN to validate its license and download security feature updates, including databases and engines for security feature updates, such as AntiVirus and IPS. You can configure a FortiGate to use a local FortiManager for both license validation and FDN updates.

For a FortiGate that doesn't have Internet access, you must complete the full configuration before you upload the license. When the FortiGate receives a license file (from the GUI or CLI), it immediately attempts to access the public FDN to validate the license. Until the license is validated, you can't log in to the GUI and some CLI commands aren't available, including the commands that you need to define a local FDN server. This makes it very difficult for you to add the necessary commands to point the FortiGate to a local FortiManager to validate the license.

This document describes how to configure a FortiGate for local FDN access, and provides you with a workaround to fix a FortiGate that can't access a public license validation server.

Follow this procedure to configure a FortiGate to use a local FortiManager for FDN access.

If you complete these steps in a different order, the process may fail, and the FortiGate won't be able to validate the license.

In the FortiGate CLI:

1. Configure central management settings:

```
config system central-management
config server-list
edit 1
set server-type update rating
set server-address <fortimanager_ip>
next
end
set include-default-servers disable
end
```

2. Upload the license using TFTP:

```
execute restore vmlicense tftp <filename>.lic <tftp_ip>
```

The FortiGate reboots.

3. Complete the central management configuration:

```
config system central-management
set fmg <fortimanager_ip>
end
```

In the FortiManager GUI:

You must manually add devices to the FortiManager.

As a result of the CLI commands that you entered on the FortiGate, the device is displayed in the FortiManager GUI, in the **Unregistered Devices** list that's located in the **Device Manager** pane for the root ADOM.

When you enable ADOMs, you must assign the device to an ADOM when you register it.

To add devices manually:

1. Confirm that central management is enabled for the device (as above).
2. In FortiManager, select the root ADOM, and go to **Device Manager**.
3. In the tree menu, click **Unregistered Devices**. The content pane displays the unregistered devices.
4. Select the unregistered device or devices, then click **Add**.
The **Add Device** dialog box opens.
5. If ADOMs are enabled, select the ADOM in the **Add the following device(s) to ADOM** list. If ADOMs are disabled, select **root**.
6. Type the login and password for each device.
7. Click **OK** to register the devices.

The devices are added.

Configure FortiManager without Internet connectivity as a local FDN server

The FortiManager can be operated as a local FDS server when it is in a closed network with no Internet connectivity.

Without a connection to a FortiGuard server, update packages and licenses must be manually downloaded from support, and then uploaded to the FortiManager. Through this feature, known as **Closed Network Mode**, the FortiManager can then provide updates and validate licenses for local FortiGate devices without Internet access.

To configure the FortiManager in Closed Network Mode, complete the following tasks:

- [Enable Closed Network Mode](#)
- [Request FortiGate license validation information](#)
- [Download FortiGuard service update files](#)
- [Configure FortiManager in Closed Network Mode](#)

Enable Closed Network Mode

1. From the FortiManager GUI, go to **FortiGuard > Settings** and disable **Enable Communication with FortiGuard Server**.

Or, from the FortiManager CLI, enable Closed Network Mode by disabling FDS access from the public FDN:

```
config fmupdate publicnetwork
  set status disable
end
```

Once in Closed Network Mode, you must manually import FortiManager service packages, updates, and license upgrades.

Request FortiGate license validation information

1. Create a Customer Service ticket with [Fortinet Support](#) under **Assistance > Create Ticket > Customer Service > Submit Ticket**.
2. Enter the serial number. Under **Category**, select **CS Contract/License**.
3. In the **Comment** field, ask for an "entitlement file" for the FortiGate. Provide the serial number and license number available in **Asset > Manage/View Products > <Select product>**.

Example:

Serial Number: FGVM010000024628

License Number: FGVM0035444

As with asset registration, for large numbers of FortiGate devices you can attach a spreadsheet of serial and license numbers for Customer Service. They will provide a single entitlement file that contains validation information for all FortiGate devices in the spreadsheet. All FortiGate devices must be registered under the same account. Devices registered under different accounts cannot be combined into the same entitlement file.

4. You will receive an entitlement file from Customer Service.

Download FortiGuard service update files

1. From [Fortinet Support](#), navigate to **Download > FortiGuard Service Updates**. Download the **Virus Definition**, **Attack Definition**, and **Mobile Malware** files for the appropriate version of FortiGate and FortiOS. These files are named in the form vsigupdate*.pkg and nids*.pkg.
2. Export the FortiGuard Web Filter and Anti-Spam service updates from a FortiManager that has Internet connectivity by entering the following CLI command:

```
execute fmupdate {ftp | scp | tftp} export <type> <remote_file> <ip> <port>
<remote_path> <user> <password>
```

Enter types `url` and `spam`.

Variable	Description
{ftp scp tftp}	Select the file transfer protocol to use: ftp, scp, or tftp.
<type>	Select the type of file to export or import. The following options are available: av-ips, fct-av, url, spam, file-query, license-fgt, license-fct, custom-url, or domp.
<remote_file>	Update manager packet file name on the server or host.
<ip>	Enter the FQDN or the IP address of the server.
<port>	Enter the port to connect to on the remote SCP host. Range: 1 to 65535 .
<remote_path>	Enter the name of the directory of the file to download from the FTP server or SCP host. If the directory name has spaces, use quotes instead.
<user>	Enter the user name to log into the FTP server or SCP host.
<password>	Enter the password to log into the FTP server or SCP host.

Configure FortiManager in Closed Network Mode

Go to **FortiGuard > Settings** to configure FortiManager as a local FDS server and to upload update packages and licenses.

1. Toggle **OFFEnable Communication with FortiGuard Server** to disable communication with the FortiGuard servers.
2. Toggle **ONEnable Antivirus and IPS Service**.
Select software versions for FortiGate, FortiClient, FortiAnalyzer, and FortiMail.
3. Toggle **ONEnable Web Filter Service**.
When uploaded to FortiManager, the Web Filter database is displayed.
4. Toggle **ONEnable Email Filter Service**.
When uploaded to FortiManager, the Email Filter database is displayed.
5. Under **Upload Options for FortiGate/FortiMail**
 - Upload **AntiVirus/IPS Packages**. Browse for the file you downloaded from the Customer Service Support portal on your management computer. Select **OK** to upload the package to FortiManager. Repeat for each file downloaded from the Customer Service Support portal.
 - Upload **Web Filter Database**. Browse for the file you exported from the FortiManager that is connected to the Internet. Select **OK** to upload the package to FortiManager in the closed network mode. As the database can be large, uploading with the CLI is recommended. See the instructions below.

- Upload **Email Filter Database**. Browse for the file you exported from the FortiManager that is connected to the Internet. Select **OK** to upload the package to FortiManager in closed network mode. As the database can be large, uploading with the CLI is recommended. See the instructions below.
 - Select **Service License** to import the FortiGate license. Browse for the entitlement file on your management computer. Select **OK** to upload the package to FortiManager. A license file can be obtained from support by requesting your account entitlement for the device (see ["Configuring FortiGuard licensing for devices with limited or no connectivity" on page 2372](#)).
6. Under **Upload Options for FortiClient**, select **AntiVirus/IPS Packages** to upload the FortiClient AntiVirus/IPS packages. Browse for the file downloaded from the Customer Service & Support portal on your management computer. Select **OK** to upload the package to FortiManager.

Uploading packages with the CLI

You can upload packages and licenses with the CLI. You should use this method when packages are large, such as database packages.

First, disable communications with the FortiGuard server and enable a closed network with the following CLI commands:

```
config fmupdate publicnetwork
  set status disable
end
```

Then, upload an update package or license by loading the package or license file to an FTP, SCP, or TFTP server.

Run the following CLI command:

```
execute fmupdate { ftp | scp | tftp } import < av-ips | fct-av | url | spam | file-query |
  license-fgt | license-fct | custom-url | domp > <remote_file> <ip> <port> <remote_
  path> <user> <password>
```

Troubleshooting your FortiGuard connection

You can use the following commands to determine the state of license validation and FDN service connectivity, and gather information about connectivity failures. For more information about troubleshooting commands, see the [FortiOS CLI Reference](#).

On a FortiGate, use the following commands:

- `get system status`
- `get webfilter status`
- `get system auto-update version`
- `get system auto-update status`

On a FortiGate VM, use the following commands:

- `diagnose hardware sysinfo vm full`
- `diagnose debug vm-print-license`
- `diagnose hardware sysinfo vminfo`

On a FortiManager, use the following commands:

- `diagnose fmupdate vm-license`

Firmware updates

A FortiManager can also perform firmware updates for multiple FortiGate devices which saves you time because you don't have to upgrade each FortiGate individually.

The FortiManager stores local copies of firmware images, when it downloads images from the Fortinet Distribution Network (FDN) or accepts firmware images that you upload from the management computer.

If you use the FortiManager to download firmware images, the FDN first validates device licenses and support contracts and then provides a list of firmware images that are currently available. For devices with valid Fortinet Technical Support contracts, you can download new firmware images from the FDN and the firmware release notes. After firmware images are downloaded, you can either schedule or immediately upgrade or downgrade the firmware for a device or a group of device.

For more information about updating the FortiGate firmware using FortiManager central management, see the [FortiManager Administration Guide](#).

Administrative domains

FortiManager administrative domains allow the super_admin to create groupings of devices for configured administrators to monitor and manage. FortiManager can manage a large number of Fortinet appliances. This allows you to maintain managed devices that are specific to their geographic location or business division. This also includes FortiGate devices with multiple VDOMs.

Each administrator is tied to an administrative domain (ADOM). When the administrator logs in, they see only those devices or VDOMs that are configured for that administrator and ADOM. The one exception is the super_admin account that can see and maintain all administrative domains and the devices within those domains.

Administrative domains aren't enabled by default and only the super_admin can enable and configure the domains.

The maximum number of administrative domains you can add depends on the FortiManager system model. For more information about the maximums for each model, see the [FortiManager Administration Guide](#).

Backing up and restoring configurations

A FortiManager stores configuration files for backup and restore purposes. A FortiManager also allows you to save revisions of configuration files. Configuration backups occur automatically when you log out or the administrator login session expires.

FortiManager also allows you to view differences between different configurations so that you can identify where changes have been made.

FortiManager in backup mode

Running a FortiManager ADOM in backup mode allows you to use the FortiManager as a central database for address and service objects which are common across multiple devices that are connected to that ADOM. When a FortiManager ADOM is in backup mode, the FortiManager administrator is responsible for managing the database but not the FortiGate configurations.

FortiGate administrators are responsible for making changes to FortiGate devices. When changes are made, the FortiGate administrator is notified of any new, updated, or out-of-sync objects. The administrator can import or update these objects, as needed.

When the FortiManager is in backup mode, the FortiGate configuration is synchronized on demand with FortiManager, similar to how it is done in normal mode and keeps the FortiManager and FortiGate closely synchronized.

Backup mode is useful when you have networks in multiple locations, each with their own administrators who require the ability to make changes quickly.

To add a FortiManager in backup mode, you must first configure an ADOM on the FortiManager that is in backup mode. You can then add the FortiGate to that ADOM using the **Central Management** settings, found at **Security Fabric > Settings**. Make sure to set **Mode** to **Backup**.

To access shared objects from the FortiManager, select the Central Management icon in the GUI header and select **View Details**. A menu opens, showing all FortiManager objects, with options to import, update, or delete objects as necessary.

Chapter 21 - Security Profiles

This FortiOS Handbook chapter contains the following sections:

- [What's New in FortiOS 6.0](#) describes the new security profile features in FortiOS 6.0
- Inside FortiOS highlights the features and benefits of key FortiOS 6.0 components. The technical documentation team maintains these documents as part of the Handbook and as standalone documents which are available at Fortinet's Online Help. Inside FortiOS covers the following security profiles topics:
 - [AntiVirus](#)
 - [Application Control](#)
 - [Intrusion Prevention System](#)
 - [Web Filtering](#)
- [Security profiles overview](#) describes Security Profiles components and their relation to firewall policies, as well as SSL content scanning and inspection.
- [Inspection Modes](#) discusses the FortiGate's inspection modes and how the security profiles function depending on inspection mode.
- [AntiVirus](#) explains how the FortiGate unit scans files for viruses and describes how to configure the antivirus options.
- [Web filter](#) describes basic web filtering concepts, FortiGuard Web Filtering, the order in which the FortiGate unit performs web filtering, and configuration.
- [DNS filter](#) explains how to configure the Domain Name System (DNS) Filter security profile independent of the Web Filter security profile.
- [Application control](#) describes how your FortiGate unit can detect and take action against network traffic based on the application generating the traffic.
- [Intrusion prevention](#) explains basic Intrusion Protection System (IPS) concepts and how to configure IPS options; includes guidance and a detailed table for creating custom signatures as well as several examples.
- [Anti-spam filter](#) explains how the FortiGate unit filters email, how to configure the filtering options, and which actions to take when spam is detected.
- [Data leak prevention](#) describes the DLP features that allow you to prevent sensitive data from leaving your network and explains how to configure the DLP rules, compound rules, and sensors.
- [ICAP support](#) describes how to offload traffic to a separate server specifically set up for the specialized processing of the traffic.
- [FortiClient Compliance Profiles](#) addresses the FortiClient Profiles endpoint protection features and configuration.
- [SSL/SSH Inspection](#) presents SSI and SSH content scanning and inspection with your FortiGate.
- [Custom Application & IPS Signatures](#) describes how to create custom Application Control and IPS signatures.
- [Other security profiles considerations](#) addresses topics like Security Profiles VDOMs, conserve mode, using wildcards and Perl regular expressions, adding External Security Devices, CPU allocation and tuning commands to survive reboot and so on.

What's new in FortiOS 6.0.1

The following list contains new Security Profile features added in FortiOS 6.0.1. Click on a link to navigate to that section for further information.

- ["Option for "Suspicious Files Only" for FortiSandbox submissions" on page 2425](#)

What's new in FortiOS 6.0

The following list contains new Security Profile features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

Inside FortiOS: AntiVirus

AntiVirus uses a suite of integrated security technologies to provide against a variety of threats, including both known and unknown malicious codes (Malware), plus Advanced Targeted Attacks (ATA), also known as Advanced Persistent Threats (APT).

Advanced protection against malware and APTs

Malware and Advanced Persistent Threats can cause significant damages to today's organizations. These malicious codes are commonly designed to steal valuable data, gain unauthorized access, or cause products to degrade. FortiOS's AntiVirus is an industry-proven anti-malware security solution with robust features and deployment options

FortiOS offers the unique ability to implement both Flow- and Proxy-based AV concurrently, depending on traffic type, users, and locations. Flow-based AV offers higher throughput performance while proxy-based solutions are useful in mitigating stealthy malicious codes. The AV detection capabilities are further enhanced with complementary security features and external sandbox integration.

By utilizing the unique Content Pattern Recognition Language (CPRL) built into the FortiASIC Content Processor, FortiOS is able to deliver high performance and low latency anti-malware capabilities. This real-time protection is backed by a team of worldwide researchers.

Highlights

- Certification from multiple industries for best-in-class security and capacity with proven coverage and high performance.
- Multi-layered protection with extended AV components and external file analysis integration.
- Comprehensive remediation actions such as file quarantine and knowledge tools.

Key Features & Benefits

Robust feature set	Allows the flexibility to deploy appropriate protection according to security needs and infrastructure designs.
High performance utilizing FortiASIC and patented CPRL AV signatures	Low latency and high capacity ensures that business applications are not affected while security is enforced.
Backed by FortiGuard Labs that deliver real-time protection	Critical digital assets are covered by continuous protection against latest threats.

Features

Industry's validated protection

FortiOS anti-malware components and FortiGuard AV signatures periodically undergo numerous authoritative certifications. These independent certifications demonstrate that the solution offered is of the highest standard in

performance and accuracy, ensuring organizations are truly protected.

Fortinet has been consistently ranked among the top vendors for Virus Bulletin's RAP (Reactive And Proactive) bimonthly tests. This test measures a product's detection rates over the freshest samples available, as well as samples not seen until after product databases are frozen, thus reflecting both the vendor's ability to handle the huge quantity of newly emerging malware and accurately detect previously unknown malware.

Real time protection

The FortiGuard AntiVirus Service provides fully automated updates to ensure protection against the latest content-level threats via the experienced FortiGuard global network is backed by over 200 researchers. With the release of FortiOS 5.6, botnet protection is part of the FortiGuard AntiVirus contract.

FortiGuard AV service quick facts

- 95,000 malware programs neutralized per minute
- 1.8 Million new and updated AV definitions per week
- Hourly updates of the AV signature database
- 190 TB of threat samples till date

Organizations can also engage the FortiGuard Premier Signature Service, which provides enhanced virus detection and threat analysis support. This service offers submissions for custom AntiVirus signatures on a daily basis, offering prioritized support with guaranteed response times. With the release of FortiOS 5.6, botnet protection is part of the FortiGuard AntiVirus contract.

Unique proxy- and flow-based AV

FortiOS offers organizations the flexibility to select the most appropriate inspection method for different network sessions. This can be implemented by defining policies that match specific source objects (IP, IP ranges, users, and devices), destination objects, applications, and schedules with different AV profiles.

Flow-based AV relies on IPS technology where packets are inspected in real-time and matched against the AV signature database. It offers lower latency and higher throughput than Proxy-based AV. Flow-based AV is recommended for inspecting traffic that requires spontaneous user experience or when serving as an additional AV protection layer.

FortiOS's Proxy-based AV offers the most secure AV protection as it's able to inspect more protocols and provides replacement messages on wider range of applications.

AV acceleration with Content Processor

The FortiASICS Content Processor (CP) accelerates content processing traditionally performed completely by the CPU. The CP reduces the resources required by the CPU when matching an incoming file against the signature database, thus improving system performance and stability.

Proactive protection using patented CPRL

Compact Pattern Recognition Language (CPRL) is a patented and proprietary programming language that allows for further inspection of common patterns to not only protect against threats and their variants but also to predict tomorrow's zero-day malware. It allows FortiGuard analysts to describe entire families of malware with a single program, instead of the traditional signature-based "one signature, one variant" model used by other vendors. With fewer signatures to match, throughput performance and latency naturally improve.

Intelligent behavioral evaluation

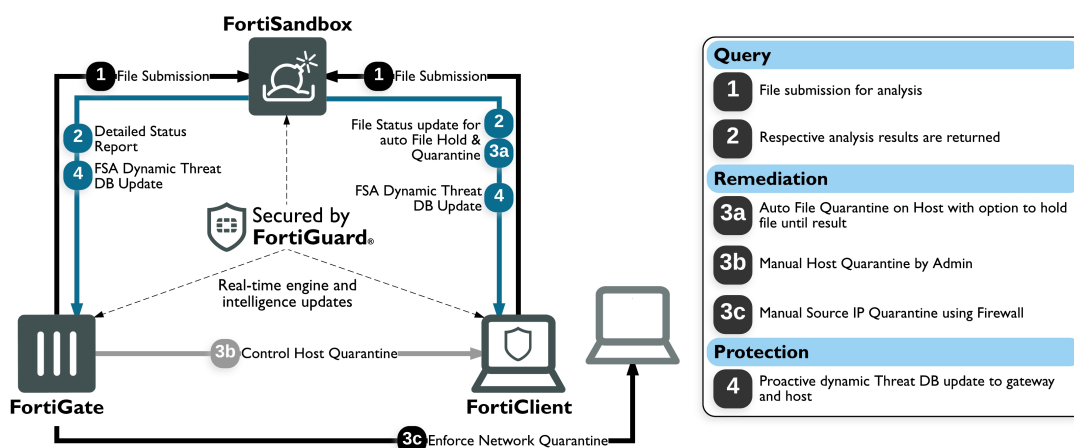

Signature-based security alone is no longer sufficient; it is now critical to understand how devices on your network are behaving. Threat Weight scoring provides a cumulative security ranking of each client device on your network based on a range of behaviors. It provides specific, actionable information that helps identify compromised systems and potential zero-day attacks in real-time.

This unique system attaches predefined scores to various malicious network activities discovered by IPS, application control, URL filtering, etc., to determine the top suspicious users. Administrator can then further inspect these users to undercover unknown threats or APTs via FortiView.

External file analysis integration

FortiOS offers organizations the ability to adopt robust ATP (Advanced Threat Protection) framework that reaches mobile users and branch offices, detecting and preventing advanced attacks that may bypass traditional defenses by examining files from various vectors, including encrypted files. To detect unknown threats, zero-day, and targeted attacks, the FortiGate can engage external resources to perform additional file analysis. Files can be submitted to an on-premise appliance (FortiSandbox) or cloud-based service (FortiSandbox Cloud) after both proxy-based and flow-based AV processing.

It is also possible to configure the FortiGate to automatically receive dynamic signature updates from FortiSandbox and add the originating URL of any malicious file to a blocked URL list. In addition, if the organization deploys integrated endpoint control with FortiClient, an administrator can instruct an infected terminal to self-quarantine.

File filtering

File filtering using data leak prevention (DLP) on the FortiGate offers an effective ways to stop unwanted file transmission instantly. Administrators may implement granular file controls by defining protection profiles using filenames or nearly 50 different file types over mail, web, and file download protocols.

File quarantine

FortiOS offers sophisticated file quarantine capabilities that allow organizations to archive suspicious or blocked files for further examination or to release false positives.

Anti-bot

Organizations may prevent, uncover, and block botnet activities using FortiOS Anti-Bot traffic pattern detection and domain and IP reputation services supplied in real-time by FortiGuard threat experts.

User notification

User notifications are helpful in reducing administration and support burdens, as well as providing user education. FortiOS is able to automatically replace blocked attachments and downloads with detailed information sent to E-mail, FTP, or web users.

Monitoring, logging, and reporting

FortiOS empowers organizations to implement security best practices that require continuous examination of their threat status and adaptation to new requirements. The FortiView widgets provide useful analysis data with detailed and contextual session information, which can be filtered, ranked, and further inspected. System events can also be archived via logs, which in turn can generate useful trending and overview reports.

FortiOS also offers robust in-built E-mail and SMS alert systems, as well as integration with external threat management systems using SNMP and standard-based Syslogs.

Inside FortiOS: Application Control

Application control technologies detect and take action against network traffic based on the application that generated the traffic. Application control uses protocol decoders with signatures that analyze network traffic to detect application traffic, even if the traffic uses nonstandard ports or protocols.

Enhance control and network visibility

Controlling and monitoring applications on a network can seem like a daunting task due to the wide range of available applications. It is no longer an option to simply block or allow TCP and/or UDP ports since most applications do not map to individual ports. For example, controlling traffic on an HTTP or HTTPS port is futile against complex social networking sites and cloud applications.

FortiOS leverages its massive application database to identify applications and their activities while still providing a suitable and sufficient user experience, thanks to FortiASIC Content Processors (CPs), which boost CPU performance. Organizations can adopt more granular control, such as allowing logins but not chatting over selected sites. Traffic shaping may also be applied to the application traffic that is allowed. After applying control measures, continuous monitoring ensures that the measures are effective and allow for changes in application traffic patterns to be managed.

Highlights

- Superior performance using the unique FortiASIC Content Processor that offloads heavy computation from the CPU.
- Flexible implementation with robust deployment modes and granular controls.
- Excellent visibility and management tools that help administrators improve security.
- Application control is a standard part of any FortiCare support contract and the database for Application Control signatures is separate from the IPS database. Access to the database no longer requires a FortiGuard IPS subscription.

Updates for the Application Control signature database require a valid FortiCare support contract.

- Supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).
- Ability to configure application control by adding individual applications or application categories to security policies when operating in flow-based inspection and NGFW policy-based mode.

Key features & benefits

Identifies and controls application traffic	Allows organization to strengthen security policies by controlling evasive application communications.
Leverages FortiGate's hardware acceleration and software optimization	Offers more security without compromising performance.

Granular control and integration with other FortiOS capabilities

Provides administrators the ability to implement the most appropriate configuration for any given organization.

Features

NSS Labs “Recommend” rating for Next Generation Firewall

Fortinet’s entry into the NSS Labs Next Generation Firewall Group Test in 2013, 2014 and 2016 received the “Recommend” rating, placing it as one of the top performing systems. NSS Labs uses respectable real-world testing methodologies to measure Next Generation Firewall protection and performance, including application control.

Superior performance with unique hardware architecture

Unlike a traditional security gateway, which relies heavily on CPUs for packet inspection, the FortiGate’s unique hardware architecture allows FortiOS to automatically utilize appropriate hardware components to achieve optimal performance. This prevents the CPU from becoming a bottleneck as it performs various functions concurrently.

In support of application control, the Content Processor (CP) is a specialized ASIC chip that handles demanding cryptographic computation for SSL inspection and intensive signature matching. By offloading these processes from the CPU, the FortiGate is able to minimize performance degradation when administrators opt for greater security.

Robust deployment modes

FortiOS supports a wide array of network protocols and operating modes, allowing administrators to deploy the most appropriate security for their unique IT infrastructure. FortiOS also supports a variety of routing and switching protocols.

The FortiGate is able to operate in inline route and transparent mode. It can also operate in offline sniffer mode for passive monitoring of user activities. These different operating modes run concurrently by using virtual systems.

Protection at the edge

With today’s BYOD and mobile workforce environment, it is no longer wise to deploy control just at the Internet gateway. Through Fortinet Security Fabric, FortiOS unique wireless and switch controller feature allows organizations to implement better visibility and protection closer to internal devices. Moreover, with FortiClient, administrators can also apply similar policies when mobile users are outside of the protected networks.

Advanced application detection and control

By relying on the FortiOS 3rd Generation IPS engine, the FortiGate is able to inspect many of today's encrypted and evasive traffic, as well as traffic running on new technologies, such as SPDY protocol. The inspection can be applied to both network and IPsec/SSL VPN traffic.

An application and its specific activity are identified using FortiGuard's Application Control database of over 2,500 distinct signatures. These signatures are crafted by researchers across the globe to include applications that may be unique to platforms, regions, and/or languages. It also offers specific application activity identification, such as a Facebook posting or Dropbox file sync. The database is kept up to date via scheduled or manual downloads.

The application database is classified into 20 intuitive categories for ease of use. Administrators may also create specific application overrides that differ from the category settings. These specific applications can be filtered and selected by type of behavior, risk levels, technology type, application vendor and popularity.

Administrators may also apply advanced controls, such as setting up session TTLs for specific applications using CLI commands.

Traffic shaping

Organizations may better utilize bandwidth and protect critical applications by enforcing granular application usage with traffic shaping. Administrators can create various traffic shaping profiles by defining traffic priority and maximum or guaranteed bandwidth. These profiles can then be assigned to targeted applications.

User notification

User education is central to an effective security implementation. In response to this, FortiOS lets you provide user notification when blocking an unauthorized application. The notification appears as an HTML block page for web-based applications.

Advanced notification is possible by implementing Fortinet's browser-embedded frame. And when "off-net" users are denied access, notifications appear via FortiClient's notification pop-ups.

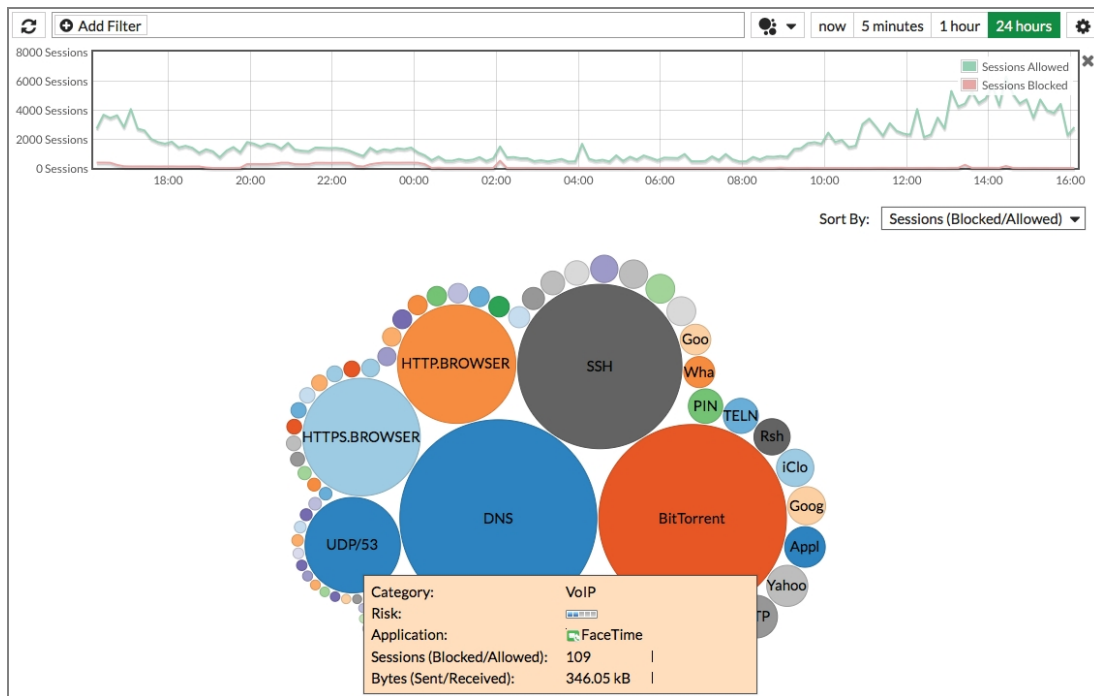

Deep inspection for cloud applications

The prevalence of cloud applications like Dropbox poses a security challenge to today's organizations. Using FortiOS's deep inspection for popular cloud applications, administrators gain deep and useful insights, via FortiView and logs, into activities associated with these applications, such as user IDs, cloud actions, file names, and file sizes. For popular video sites, FortiOS will also be able to track video files viewed.

SSL inspection for encrypted traffic

SSL (Secure Sockets Layer) is a popular encryption standard used to protect Internet traffic but may also be used to evade traditional inspection. FortiOS enables organizations to adopt effective application control even when traffic is encrypted.

Unique hardware components and software optimizations can decrypt traffic with minimal performance impact. The inspection can easily omit sensitive communications, such as financial transaction (thereby complying with privacy policies), or bypass applications that forbid SSL inspection by using granular policy settings.

Monitoring, logging, and reporting

FortiOS empowers organization to implement security best practices that require continuous examination of threat statuses and the ability to adapt to new requirements.

The FortiView widgets provide useful analyses with detailed and contextual session information that can be filtered, ranked, and further inspected. For example, an administrator can instantly query the top applications that are currently consuming bandwidth and drill down to identify their users and help decide if such activities should be blocked.

Network, threat, and system events activities can be archived via syslogs. In turn, these logs can generate useful trending and overview reports.

Lastly, the FortiOS offers robust in-built email and SMS alert systems. Meanwhile, integration with external threat management systems can be achieved with SNMP and standard-based syslogs.

- NGFW policy-based mode

Inside FortiOS: Intrusion Prevention System (IPS)

Intrusion Prevention System (IPS) technology protects your network from cybercriminal attacks by actively seeking and blocking external threats before they can reach potentially vulnerable network devices.

World class next generation IPS capabilities

Today, sophisticated and high volume attacks are the challenges that every organization must recognize. These attacks are evolving, infiltrating ever-increasing vectors and complex network environments. The result is an urgent need for network protection while maintaining the ability to efficiently provide demanding services and applications.

FortiOS's IPS functionality is an industry-proven network security solution that scales up to over 200 Gbps of in-line protection. Powered by purpose-built hardware and FortiASICs, FortiOS is able to achieve attractive TCO while meeting performance requirements. IPS is easy to set up, yet offers feature-rich capabilities, with contextual visibility and coverage. It is kept up-to-date by research teams that work 24 hours a day worldwide, in order to detect and deter the latest known threats as well as zero-day attacks.

Highlights

- Validated best-in-class security and capacity with proven coverage and high performance.
- Comprehensive protection provided by a signatures-based IPS engine, protocol anomaly scanning, and DDOS mitigation.
- Flexible deployment options and actionable implementations for a wide array of network integration and operation requirements.

Key features & benefits

High Performance IPS, powered by FortiASIC	Low latency and high capacity ensure business applications are not affected while security is enforced.
Best-in-class security with superior coverage	Protects critical digital resources from both internal exploits and external cybercriminals, even if sophisticated attacks are crafted.
Backed by FortiGuard Labs that deliver real-time protection	Maintains up-to-date and proactive protection against latest known threats and newly discovered hacking techniques while allowing time for organizations to patch vulnerable systems.

Features

Tested and proven protection

Not only have FortiGates been deployed in some of the largest enterprises in the world since 2002, FortiOS IPS components and FortiGuard IPS signatures are periodically tested and certified by well-known external labs. For example, Fortinet's FortiGate 3000D earned the highest ratings for Security Effectiveness, blocking 99.9 percent

of exploits in the recent NSS Labs DCIPS test. These independent certifications ensure that solutions delivered to customers are of the highest standards in performance, coverage, and accuracy.

Real-time & zero-day protection

The FortiGuard Intrusion Prevention Service (IPS) provides customers with the latest defenses against stealthy network-level threats through a constantly updated database of known threats and behavior-based signatures.

FortiGuard IPS service quick facts

- Over 10,000 signatures consisting of 18,000 rules
- Approximately 470,000 network intrusion attempts resisted per minute
- About 1,000 rules are updated or added per week
- Over 300 Zero-day vulnerabilities discovered to date

This update service is backed by a team of threat experts and a close relationship with major application vendors. The best-in-class team also uncovers significant zero-day vulnerabilities continuously, providing FortiGate units with advanced protection ahead of vendor patches.

Uncompromised performance

The FortiASICS Content Processor (CP) accelerates content processing, which is traditionally done completely by the CPU. The CP reduces the resources required by the CPU when matching an incoming file against the signature database, thus improving system performance and stability.

Protocol decoders and anomaly detection

Protocol decoders are required to assemble the packets and detect suspicious, nonconforming sessions that resemble known attacks or are non-compliant to RFC or standard implementation.

FortiOS offers one of the most comprehensive arrays of protocol decoders in the industry, providing customers with significantly wide coverage in all kinds of environments.

Pattern & rate-based signatures

The pattern signature matching technique is essential in IPS implementation due to its high level of precision and accuracy. FortiOS offers administrators robust pattern signature selection using filters based on severity, target, operating system, application, and protocol. Each of the 10,000+ signatures has a direct link to its detailed entry on the threat encyclopedia and CVE-ID references. After selection, administrators are able to assign associated actions such as monitoring, blocking, or resetting the session.

Rate-based IPS signatures protect networks against application based DoS and brute force attacks. Administrators can configure nearly 30 rate-based IPS signatures and tune them to their needs. Threshold (incidents per minute) and an action to take when the threshold is reached can be assigned to each signature. If the action is set to block, then a timeout period can be set so that the block is removed after a specified duration.

DoS and DDoS mitigation

DoS policies can help protect against DDoS attacks that aim to overwhelm server resources. In FortiOS, the DoS scans precede the policy engine at the incoming interfaces, thus eliminating unnecessary sessions from the

firewall process and state table entry during a surge of attack traffic. This helps to safeguard the firewall from overloading and allows it to perform optimally.

FortiOS DoS policies can be configured to detect and block floodings, port scans, and sweeps. Administrators can set baselines for the amount of concurrent sessions from sources or to destinations. The settings utilize thresholds and can be applied to UDP, TCP, ICMP, IP, and SCTP.

Network interfaces associated with a port attached to a Network Processor (NP) can be configured to offload anomaly checking, further offloading the CPU for greater performance. Some of the anomaly traffic dropped includes LAND attacks, IP protocol with malformed options, and WinNukes.

Quarantine attacks

FortiOS offers sophisticated automatic attack quarantine capabilities which allow organizations to proactively prevent further attacks from known attackers over a predefined duration. Quarantining by duration can be used to protect potentially vulnerable servers until more permanent defense.

Packet logging

Administrators may choose to automatically perform IPS packet logging, which saves packets for detailed analysis when an IPS signature is matched. Saved packets can be viewed and analyzed on the FortiGate unit or by using third-party analysis tools. Packet logging is also useful in determining false positives.

Custom signatures

Custom IPS signatures can be created to further extend protection. For example, you can use custom IPS signatures to protect unusual or specialized applications, or even custom platforms from known and unknown attacks.

Organizations may use FortiConverter to easily convert Snort signatures for FortiOS use.

Apply

Resistant against evasions

Evasion techniques attempt to fool the protocol decoders in IPS products by crafting exotic network streams that would not be handled or reconstructed by the decoders, yet still be valid enough for the target recipient to process. Robust IPS engine is capable of handling both common evasions and sophisticated AETs (Advanced Evasion Techniques) deployed by hackers such as IP Packet Fragmentation, TCP Stream Segmentation, RPC Fragmentation, URL & HTML Obfuscation, and other protocol specific evasion techniques.

Intrusion detection mode

In out-of-band sniffer mode (or one-arm IPS mode), IPS operates as an Intrusion Detection System (IDS), detecting attacks and reporting them but not taking any action against them. In sniffer mode, the FortiGate unit does not process network traffic and instead is connected to a spanning or mirrored switch port, or a network tap. If an attack is detected, log messages can be recorded and alerts sent to system administrators.

Traffic bypass

Since most IPS deployments are in transparent inline mode, active traffic bypass is often desired until normal operation of the device resumes. Some FortiGates offer inbuilt active bypass interfaces while others may use external bypass devices such as the FortiBridge. Administrators are also offered with software fail-open option to tackle instances where the IPS engine fails.

Monitoring, logging, and reporting

FortiOS empowers organizations to implement security best practices that require continuous examination of their threat status and adaptation to new requirements. The FortiView query widgets provide useful analysis data

with detailed and contextual session information, which can be filtered, ranked, and further inspected. System events can also be archived via logs, which in turn can generate useful trending and overview reports.

Inside FortiOS: Web Filtering

A Web Filtering solution is designed to restrict or control the content a reader is authorized to access, delivered over the Internet via the Web browser. It may be used to improve security, prevent objectionable activities, and increase productive within an organization.

Intelligent and effective content control

Web-based threats such as Phishing, drive-by Malware sites, and Botnets are more sophisticated and scrutinized than ever, and as well as increasingly difficult to control due to the rise of mobility in the workplace, even more difficult for you to control. The Web has become the preferred medium of choice for hackers and thieves looking for new ways to disrupt services, steal information, and perform malicious activities for financial gain. In addition, employees who visit websites containing objectionable content can expose your organization to civil or criminal liability.

FortiOS Web Filtering solution utilizes three main components of the web filtering function: the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service. These functions integrate with each other to provide maximum control over what the Internet user can view as well as protection to the network from many Internet content threats. Web Content Filtering blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic by independent real-world tests.

Highlights

- Comprehensive and advanced Web Filtering features Safe Search and user override options.
- FortiGuard Web Filtering Services with superior coverage of over 250 million rated websites.
- Integration with other FortiOS components, such as User Identification for flexible and secured implementation.
- Supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).
- Ability to configure web filtering by adding URL categories to security policies when operating in flow-based inspection and NGFW policy-based mode. You can set the action to accept or deny to allow or block the applications.

Key features & benefits

Cloud-based Rating Database	Real-time website category rating provides accurate content control.
Wide choice of web filtering technologies	Various web filtering technology options are available to provide each organization the most suitable implementation.
Integrated with other security and networking functions	Allows organizations to simplified networks and reduce TCO.

Features

Cloud-based rating system

Fortinet is a pioneer in cloud-based rating systems for web filtering. FortiOS provides an innovative approach to HTTP and HTTPS web filtering technology by combining the advantages of a cloud-based service offering with layered response caching. The multiple FortiGuard data centers around the world hold the entire categorized URL database and receive rating requests from FortiGate units triggered by browser-based URL requests. FortiGuard responds to these rating requests with the categories stored for specific URLs, the requesting FortiGate unit then uses its own local profile configuration to determine what action is appropriate to the category, such as: blocking, monitoring, allowing the page, displaying a warning, or requiring authentication to view the page.

Rating responses are also cached directly in FortiGate unit memory so that ratings for frequently used sites can be retrieved directly from the cache, reducing the number of requests to the FortiGuard network. Caching URLs in memory makes URL lookups almost instantaneous while only using a very small amount of system memory.

An appropriately licensed FortiManager appliance can be synchronized to the FortiGuard network and as such can be used in the same way to as the FortiGuard network for managed FortiGate devices. This can further reduce any latency associated with the round trip time for individual rating requests while at the same time ensuring complete database coverage. Consider the combination of a LAN attached FortiGate cluster and FortiManager combination with the potential to handle tens of thousands of requests per second.

Superior coverage

FortiGuard Web Filter ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. This service currently rates more than 250 million sites covering billions of URLs with each site able to be rated in multiple categories. The FortiGuard database provides a truly international service with support for 70 languages.

Extensive and flexible categorization

Rated URLs are assigned into one of the 98 categories (including 20 user defined ones) which administrators can then easily manage and control. Administrators can configure and populate local categories or place specific URLs in existing categories should the FortiGuard rating not be in agreement with an organization's policies and practices.

Rating override

At times, administrators may have to allow approved people to access what they need during periods when an exception to the normal rules is required, while still having enough control that the organization's web usage policies are not compromised. FortiOS can provide such setup by using alternate profiles.

Protection against malicious URLs

The malicious URL database contains all malicious URLs active in the last month and is organized as one of the categories. With Fortinet Security Fabric, customers can further their protection by having the FortiSandbox add newly discovered URLs to a dynamic URL filter, thus blocking files from being downloaded again from that URL.

Inspection modes

FortiOS web filtering can operate in different modes: proxy-based and flow-based inspection modes and DNS filtering. Each mode has strengths and weaknesses and all three can be active at the same time on different traffic streams.

Proxy-based web filtering uses a proxy to assemble and analyze web content as it passes through the FortiGate unit. If a page is blocked the proxy can replace the blocked page with a customizable web page informing users that the page is blocked. Proxy-based web filtering is the most feature-rich mode, supporting many advanced filters including web content filtering that analyzes web page content according to your custom requirements, Java applet filtering, and blocking invalid URLs.

Flow-based web filtering uses the FortiOS IPS engine to filter web content packets as they pass through the FortiGate unit without any buffering. Flow-based inspection does not use a proxy, so inspected packets are not proxied and altered by the FortiGate unit. Flow-based inspection does not support as many advanced features as proxy-based web filtering.

To control your FortiGate's security profile inspection mode in FortiOS 5.6, you can select **Flow** or **Proxy Inspection Mode** from **System > Settings**. Having control over flow and proxy mode is helpful if you want to ensure that only flow inspection mode is used.

In most cases proxy mode is preferred because more security profile features are available and more configuration options for these individual features are available. Some implementations, however, may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used.

Two new policy modes are available in FortiOS 5.6.

- NGFW mode simplifies applying application control and web filtering to traffic by allowing you to add applications and web filtering profiles directly to policies. This is used in conjunction with flow-based inspection.
- Transparent proxy allows you to apply web authentication to HTTP traffic without using the explicit proxy.

DNS web filtering employs DNS lookups to the FortiGuard DNS service to get web page ratings. Filtering is done as part of the DNS lookup and web pages can be blocked or redirected to a web filter block page before the HTTP session starts. As a result, it is lightweight in terms of resource usage although it only supports a limited number of advanced features.

Usage quota

Administrators can set a daily timed access quota by category or category group. Quotas allow access for a specified length of time or traffic volume, calculated separately for each user.

SafeSearch

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch on the FortiGate for the supported search sites can better enforce its use by rewriting the search URL to include the code to indicate the use of the SafeSearch feature.

Restrict YouTube access

In FortiOS 5.6 with inspection mode set to proxy-based, you can set Strict or Moderate access to YouTube in a Web Filter profile.

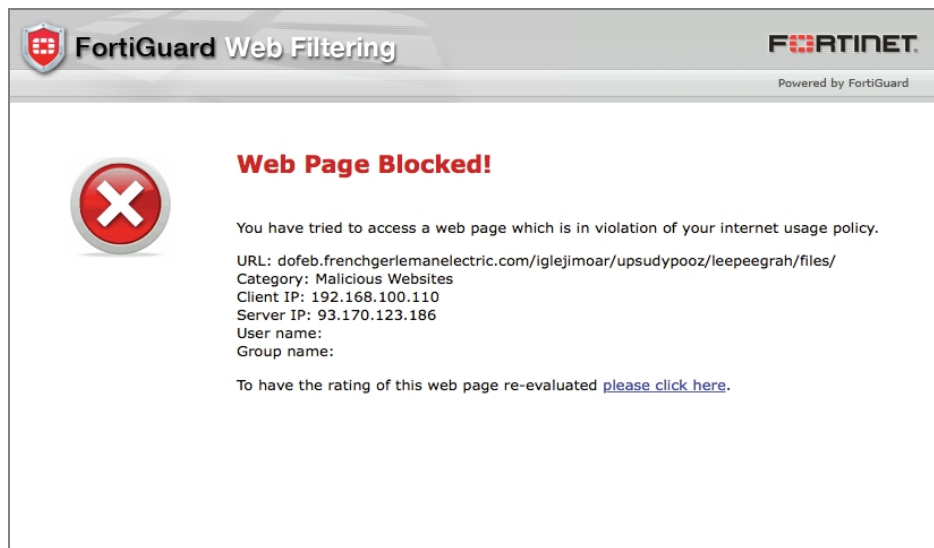

Manual URL and content filter

FortiOS web filtering offers specific URL filtering by standard, wildcard, and regular expression definition, as well as content filtering by pattern type and language.

Advanced web filter configurations

FortiOS rich feature set includes ability to implement a number of enterprise features such as:

- Block HTTP redirects by rating, invalid URLs, HTTP POST actions, and Web resume download
- Cookie, Java applet, and ActiveX filter
- Rate Images by URL and URLs by domain and IP address
- Restrict Google account usage to specific domains

Proxy avoidance preventions

FortiGate is able to improve the effectiveness of the web filtering by preventing users from evading the security implementation. Organizations can use its multiple integrated technologies including proxy site URL, proxy application control, and IPS proxy behavior blocking.

User and device awareness

Most networks in today's organizations are connected with both corporate and personal mobile devices. User and device awareness provides the option to configure intelligent policies that can effectively enforce security.

To tackle the prevalence of BYOD environments, administrators are able to configure web content access policies with sources defined by IPs, users, and devices, either combined or selectively.

External URL filtering support

In instances where customers have large, existing, deployed implementations of a specific URL filtering solution but replace their legacy firewalls with a FortiGate family, they can still retain their web filtering infrastructure since FortiOS supports both ICAP and WISP.

Monitoring, logging, and reporting

FortiOS empowers an organization to implement security best practices that require continuous monitoring of threats, allowing the organization to adapt to new requirements.

The FortiView dashboards display useful analysis data with detailed and contextual session information, which can be filtered and ranked, with drilldown options also available. This information, including system events activities and administration audit trails, can also be archived via logs.

FortiOS logs all the types of traffic that can connect to or terminate at the FortiGate unit. In turn, these logs can generate useful trending and overview reports.

Security profiles overview

The FortiGate line combines a number of security features to protect your network from threats. As a whole, these features, when included in a single Fortinet security appliance, are referred to as Security Profiles.

This overview addresses the following topics:

- [Traffic inspection](#)
- [Content inspection and filtering](#)
- [Security profile components](#)
- [Security profiles/lists/sensors](#)

Firewall policies limit access, and while this and similar features are a vital part of securing your network, they are not covered in this discussion of Security Profiles.

FortiOS 5.4 no longer supports FortiClient 5.0.

FortiOS 5.4.1 supports only FortiClient 5.4.1. Be sure to upgrade managed FortiClients before upgrading the FortiGate to 5.4.1.

FortiOS 5.2 can support FortiClient 5.0, but only if the FortiGate upgraded to FortiOS 5.2. Customers need to purchase a FortiClient 5.4 subscription-based FortiClient license.

Traffic inspection

When the FortiGate unit examines network traffic one packet at a time for IPS signatures, it is performing traffic analysis. This is unlike content analysis where the traffic is buffered until files, email messages, web pages, and other files are assembled and examined as a whole.

DoS policies use traffic analysis by keeping track of the type and quantity of packets, as well as their source and destination addresses.

Application control uses traffic analysis to determine which application generated the packet.

Although traffic inspection doesn't involve taking packets and assembling files they are carrying, the packets themselves can be split into fragments as they pass from network to network. These fragments are reassembled by the FortiGate unit before examination.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against content threats.

IPS signatures

IPS signatures can detect malicious network traffic. For example, the Code Red worm attacked a vulnerability in the Microsoft IIS web server. Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions.

IPS recommendations

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive new IPS signatures as soon as they are available.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to **Block**.
- You can view these signatures by going to **Security Profiles > Intrusion Prevention** and selecting the **[View IPS Signatures]** link in the right-hand corner of the window.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to **Block**.

Suspicious traffic attributes

Network traffic itself can be used as an attack vector or a means to probe a network before an attack. For example, SYN and FIN flags should never appear together in the same TCP packet. The SYN flag is used to initiate a TCP session while the FIN flag indicates the end of data transmission at the end of a TCP session.

The FortiGate unit has IPS signatures that recognize abnormal and suspicious traffic attributes. The SYN/FIN combination is one of the suspicious flag combinations detected in TCP traffic by the `TCP.BAD.FLAGS` signature.

The signatures that are created specifically to examine traffic options and settings, begin with the name of the traffic type they are associated with. For example, signatures created to examine TCP traffic have signature names starting with TCP.

Application control

While applications can often be blocked by the ports they use, application control allows convenient management of all supported applications, including those that do not use set ports.

Application control recommendations

- Some applications behave in an unusual manner in regards to application control. For more information, see [Application considerations on page 2490](#).
- By default, application control allows the applications not specified in the application control list. For high security networks, you may want to change this behavior so that only the explicitly allowed applications are permitted.

SSL/SSH inspection

Regular web filtering can be circumvented by using `https://` instead of `http://`. By enabling this feature, the FortiGate can filter traffic that is using the HTTPS protocol. This sort of analysis is some times referred to as deep scanning.

Deep Inspection works along the following lines: If your FortiGate unit has the correct chipset it will be able to scan SSL encrypted traffic in the same way that regular traffic can be scanned. The FortiGate firewall will essentially receive the traffic on behalf of the client and open up the encrypted traffic. Once it is finished it re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack. By enabling this feature, it allows the FortiGate firewall to filter on traffic that is using the SSL encrypted protocol.

The encrypted protocols that can be inspected are:

- HTTPS
- SMTPS
- POP3S
- IMAPS
- FTPS

Before the invention of SSL inspection, scanning regular web traffic can be circumvented by using the prefix `https://` instead of `http://` in the URL. SSL inspection prevents this circumvention. However, because when the encrypted traffic is decrypted it has to be re-encrypted with the FortiGate's certificate rather than the original certificate it can cause errors because the name on the certificate does not match the name on the web site.

At one point deep inspection was something that was either turned on or off. Now individual deep inspection profiles can be created depending on the requirements of the policy. Depending on the Inspection Profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic.
- Configure which SSL protocols will be inspected.
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure which websites will be exempt from SSL inspection
- Configure whether or not to allow invalid SSL certificates.
- Configure whether or not SSH traffic will be inspected.

Web rating overrides

This feature allows you to override the FortiGuard Web Filtering. This option allows users to change the rating for a website and control access to the site without affecting the rest of the sites in the original category. More information can be found in [Overriding FortiGuard website categorization](#).

Web profile overrides

This feature allows administrators to grant temporary access to sites that are otherwise blocked by a web filter profile. The temporary access can be granted to a user, user group, or source IP address. The time limit can be set in days, hours, or minutes. See the section on [Web Profile Overrides](#) for more information.

Content inspection and filtering

When the FortiGate unit buffers the packets containing files, email messages, web pages, and other similar files for reassembly before examining them, it is performing content inspection. Traffic inspection, on the other hand, is accomplished by the FortiGate unit examining individual packets of network traffic as they are received.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against threats to content. Be sure to understand the effects of the changes before using the suggestions.

AntiVirus

The FortiGate antivirus scanner can detect viruses and other malicious payloads used to infect machines. The FortiGate unit performs deep content inspection. To prevent attempts to disguise viruses, the antivirus scanner will reassemble fragmented files and uncompress content that has been compressed. Patented Compact Pattern

Recognition Language (CPRL) allows further inspection for common patterns, increasing detection rates of virus variations in the future.

AntiVirus recommendations

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure that new antivirus signatures are loaded onto your FortiGate as soon as they are available.
- Enable the Extended Virus Database if your FortiGate unit supports it.
- Examine antivirus logs periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.
- To conserve system resources, avoid scanning email messages twice. Scan messages as they enter and leave your network or when clients send and retrieve them, rather than both.
- Enable **Treat Windows Executables in Email Attachments as Viruses** if you are concerned about incoming '.exe' files.

FortiGuard web filtering

The web is the most popular part of the Internet and, as a consequence, virtually every computer connected to the Internet is able to communicate using port 80, HTTP. Botnet communications take advantage of this open port and use it to communicate with infected computers. FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

FortiGuard web filtering recommendations

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous.
- In the Anti-Spam profile, enable **Spam Detection and Filtering** and then enable **IP Address Check**. Many IP addresses used in spam messages lead to malicious sites; checking them will protect your users and your network.

DNS filter

DNS-based web filtering

This feature is similar to the FortiGuard DNS web filtering available in FortiOS 5.2. You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to block, the result of the DNS lookup is not returned to the requester. If the category is set to redirect, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow access or monitor access based on FortiGuard category.

The following filtering options can be configured in a DNS Filter security profile:

Blocking DNS requests to known Botnet C&C addresses

A new FortiGuard database contains a list of known Botnet C&C addresses. This database is updated dynamically and stored on the FortiGate. This database is covered by FortiGuard web filter licensing; you must have an active FortiGuard web filtering license to use this feature. You can view the botnet lists by going to **System > FortiGuard > Botnet IPs** and **System > FortiGuard > Botnet Domains**.

When you block DNS requests to known Botnet C&C addresses, using IPS, DNS lookups are checked against the Botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable blocking of DNS requests to known Botnet C&C addresses, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**. When you do this in FortiOS 5.4.1, you can open a definitions window by clicking on "botnet package."

Static URL filter

The DNS static URL filter allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

Anti-Spam

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine. The FortiGate email filter can detect harmful spam and mark it, alerting the user to the potential danger.

Anti-Spam filter recommendations

- Subscribe to the FortiGuard Anti-Spam Filtering service.
- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint scanning for protection against threats that get into your network.

Data Leak Prevention

Most security features on the FortiGate unit are designed to keep unwanted traffic out of your network while Data Leak Prevention (DLP) can help you keep sensitive information from leaving your network. For example, credit card numbers and social security numbers can be detected by DLP sensors.

DLP recommendations

- Rules related to HTTP posts can be created, but if the requirement is to block all HTTP posts, a better solution is to use application control or the **HTTP POST Action** option in the web filter profile.
- While DLP can detect sensitive data, it is more efficient to block unnecessary communication channels than to use DLP to examine it. If you don't use instant messaging or peer-to-peer communication in your organization, for example, use application control to block them entirely.

Security profile components

Below is a brief description of the security profiles and their features.

Security Profiles can be configured Globally across multiple VDOMs. See "[Global security profiles across Virtual domains \(VDOMs\)](#)" on page 2587 for more information.

AntiVirus

Your FortiGate unit stores a virus signature database that can identify more than 15,000 individual viruses. FortiGate models that support additional virus databases are able to identify hundreds of thousands of viruses. With a FortiGuard AntiVirus subscription, the signature databases are updated whenever a new threat is discovered.

AntiVirus also includes file filtering. When you specify files by type or by file name, the FortiGate unit will block the matching files from reaching your users.

FortiGate units with a hard drive or configured to use a FortiAnalyzer unit can store infected and blocked files for that you can examine later.

Web filter

Web filtering includes a number of features you can use to protect or limit your users' activity on the web.

FortiGuard Web Filtering is a subscription service that allows you to limit access to web sites. More than 60 million web sites and two billion web pages are rated by category. You can choose to allow or block each of the 77 categories.

URL filtering can block your network users from access to URLs that you specify.

Web content filtering can restrict access to web pages based on words and phrases appearing on the web page itself. You can build lists of words and phrases, each with a score. When a web content list is selected in a web filter profile, you can specify a threshold. If a user attempts to load a web page and the score of the words on the page exceeds the threshold, the web page is blocked.

DNS filter

The FortiGate will inspect DNS traffic to any DNS server, so long as the policy has DNS inspection enabled. The FortiGate will intercept DNS requests, regardless of the destination IP, and redirect it to the FortiGuard Secure DNS server -- this is separate from the FortiGuard DNS server.

The Secure DNS server will resolve and rate the FQDN and send a DNS response which includes both IP and rating of the FQDN back to the FortiGate, where it will handle the DNS response according to the DNS filter profile.

Application control

Although you can block the use of some applications by blocking the ports they use for communications, many applications do not use standard ports to communicate. Application control can detect the network traffic of more than 1,000 applications, improving your control over application communication.

Cloud Access Security Inspection (CASI)

This feature introduces a new security profile called Cloud Access Security Inspection (CASI) that provides support for fine-grained control on popular cloud applications, such as YouTube, Dropbox, Baidu, and Amazon. The CASI profile is applied to a policy much like any other security profile.

Unfortunately CASI does not work when using Proxy-based profiles for AV or Web filtering for example. Make sure to only use Flow-based profiles in combination with CASI on a specific policy.

Intrusion protection

The FortiGate Intrusion Protection System (IPS) protects your network against hacking and other attempts to exploit vulnerabilities of your systems. More than 3,000 signatures are able to detect exploits against various operating systems, host types, protocols, and applications. These exploits can be stopped before they reach your internal network.

You can also write custom signatures tailored to your network.

Anti-spam

FortiGuard Anti-Spam is a subscription service that includes an IP address black list, a URL black list, and an email checksum database. These resources are updated whenever new spam messages are received, so you do not need to maintain any lists or databases to ensure accurate spam detection.

You can use your own IP address lists and email address lists to allow or deny addresses, based on your own needs and circumstances.

Data Leak Prevention

Data Leak Prevention (DLP) allows you to define the format of sensitive data. The FortiGate unit can then monitor network traffic and stop sensitive information from leaving your network. Rules for U.S. social security numbers, Canadian social insurance numbers, as well as Visa, Mastercard, and American Express card numbers are included.

VoIP

The Session Initiation Protocol (SIP) is an IETF application layer signaling protocol used for establishing, conducting, and terminating multi-user multimedia sessions over TCP/IP networks using any media. SIP is often used for Voice over IP (VoIP) calls but can be used for establishing streaming communication between end points.

For more information, see [VoIP Solutions: SIP](#).

ICAP

This module allows for the offloading of certain processes to a separate server so that your FortiGate firewall can optimize its resources and maintain the best level of performance possible.

FortiClient profiles

FortiClient is an all-in-one comprehensive endpoint security solution that extends the power of Fortinet's Advanced Threat Protection (ATP) to end user devices. As the endpoint is the ultimate destination for malware that is seeking credentials, network access, and sensitive information, ensuring that your endpoint security combines strong prevention with detection and mitigation is critical.

The FortiGate provides network security by defining compliance rules for FortiClient endpoints.

For more information, see the [FortiClient 5.4.1 Administration Guide](#).

Proxy options

Proxy Options includes features you can configure for when your FortiGate is operating in proxy mode, including protocol port mapping, block oversized files/emails, and other web and email options.

SSL/SSH inspection

SSL/SSH Inspection (otherwise known as Deep Inspection) is used to scan HTTPS traffic in the same way that HTTP traffic can be scanned. This allows the FortiGate to receive and open up the encrypted traffic on behalf of the client, then the traffic is re-encrypted and sent on to its intended destination.

Individual Deep Inspection profiles can be created, depending on the requirements of the policy. Depending on the profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic
- Configure which SSL protocols will be inspected
- Configure which ports will be associated with which SSL protocols for inspection
- Configure whether or not to allow invalid SSL certificates
- Configure whether or not SSH traffic will be inspected

Security profiles/lists/sensors

A profile is a group of settings that you can apply to one or more firewall policies. Each Security Profile feature is enabled and configured in a profile, list, or sensor. These are then selected in a security policy and the settings apply to all traffic matching the policy. For example, if you create an antivirus profile that enables antivirus scanning of HTTP traffic, and select the antivirus profile in the security policy that allows your users to access the World Wide Web, all of their web browsing traffic will be scanned for viruses.

While you can apply more than one security profile to a firewall policy, it is not recommended that you use flow-based profiles and proxy-based profiles in the same firewall policy.

Because you can use profiles in more than one security policy, you can configure one profile for the traffic types handled by a set of firewall policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate sets of profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Inspection modes

You can select one of two inspection modes from the **System > Settings** page to control the security profile inspection mode for your FortiGate or VDOM.

- **Proxy-based inspection**, that reconstructs content passing through the FortiGate unit and inspects the content for security threats, or
- **Flow-based inspection**, that takes a snapshot of content packets and uses pattern matching to identify security threats in the content.

Each inspection component plays a role in the processing of traffic en route to its destination. Having control over flow and proxy mode is helpful if you want to be sure that only flow inspection mode is used (and that proxy inspection mode is not used). In most cases proxy mode is preferred because more security profile features are available and more configuration options for these individual features are available. Yet, some implementations may require all security profile scanning to only use flow mode. In this case, you can set your FortiGate to flow mode knowing that proxy mode inspection will not be used. While both modes offer significant security, proxy-based provides more features and flow-based is designed to optimize performance.

This section addresses the following topics:

Proxy-based inspection

If a FortiGate or VDOM is configured for proxy-based inspection, then a mixture of flow-based and proxy-based inspection occurs. Traffic initially encounters the IPS engine, which applies single-pass IPS, Application Control, and CASI, if configured in the firewall policy accepting the traffic.

The traffic is then sent for proxy-based inspection. Proxy-based inspection extracts and caches content, such as files and web pages, from a content session and inspects the cached content for threats. Content inspection takes place in the following order: **VoIP inspection, DLP, AntiSpam, Web Filtering, AntiVirus, and ICAP**.

If no threat is found, the proxy relays the content to its destination. If a threat is found, the proxy can block the threat and send a replacement message in its stead. The proxy can also block VoIP traffic that contains threats.

Transparent web proxy mode

In proxy mode, FortiOS 5.6 functions just like FortiOS 5.4 with the addition of the new Transparent Web Proxy mode. See New Operating mode for Transparent web proxy in [What's New in FortiOS 5.6](#).

Flow-based inspection

Flow-based inspection identifies and blocks security threats in real time as they are identified using single-pass Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats.

If a FortiGate or a VDOM is configured for flow-based inspection, depending on the options selected in the firewall policy that accepted the session, flow-based inspection can apply **IPS, Application Control, Web Filtering, DLP, and AntiVirus**. Flow-based inspection is all done by the IPS engine and, as you would expect, no proxying is involved.

All of the applicable flow-based security modules are applied simultaneously in one single pass, and pattern matching is offloaded and accelerated by CP8 or CP9 processors. **IPS, Application Control**, flow-based **Web**

Filtering, and flow-based **DLP** filtering happen together. Flow-based **AntiVirus** scanning caches files during protocol decoding and submits cached files for virus scanning while the other matching is carried out.

Flow-based inspection typically requires fewer processing resources than proxy-based inspection and does not change packets, unless a threat is found and packets are blocked. Flow-based inspection cannot apply as many features as proxy inspection. For example, flow-based inspection does not support client comforting and some aspects of replacement messages.

In FortiOS 5.6, flow-based inspection requires the new **NGFW mode**.

Changing between proxy and flow mode

You can see which inspection mode your FortiGate is using by looking at the **System Information** widget on your **Dashboard**.

To change inspection modes, go to **System > Settings** and scroll down to **Inspection Mode**. You can select Flow-based to operate in Flow mode or Proxy to operate in Proxy mode.

When you select **Flow-based**, all proxy mode profiles are converted to flow mode, removing any proxy settings. As well proxy mode only features (for example, Web Application Profile) are removed from the GUI.

In addition, selecting **Flow-based** inspection will cause the **Explicit Web Proxy** and **Explicit FTP Proxy** features to be removed from the GUI and the CLI. This includes Explicit Proxy firewall policies.

When you select **Flow-based** you can only configure Virtual Servers (under **Policy & Objects > Virtual Servers**) with Type set to HTTP, TCP, UDP, or IP.

If required, you can change back to proxy mode through the **System > Settings** page.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Use the top left drop-down menu to go to **Global > System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

Switching to flow-based inspection also turns off WAN Optimization, Web Caching, the Explicit Web Proxy, and the Explicit FTP Proxy making sure that no proxying can occur.

From the GUI, you can only configure antivirus and web filter security profiles in proxy mode. From the CLI you can configure flow-based antivirus profiles, web filter profiles and DLP profiles and they will appear on the GUI and include their inspection mode setting. Also, flow-based profiles created when in flow mode are still available when you switch to proxy mode.

NGFW profile-based and NGFW policy-based modes

When you select **Flow-based** as the **Inspection Mode**, you have the option in FortiOS 5.6 to select an **NGFW Mode**. **NGFW Profile-based** mode works the same as flow-based mode did in FortiOS 5.4

When selecting NGFW policy-based mode you can also select the SSL/SSH Inspection mode that is applied to all policies.

In the new **NGFW Policy-based** mode, you add applications and web filtering profiles directly to a policy without having to first create and configure Application Control or Web Filtering profiles. See [NGFW Policy Mode on page 1](#).

When you change to flow-based inspection, all proxy mode profiles are converted to flow mode, removing any proxy settings. And proxy-mode only features (for example, Web Application Profile) are removed from the GUI.

If your FortiGate has multiple VDOMs, you can set the inspection mode independently for each VDOM. Go to **System > VDOM**. Click **Edit** for the VDOM you wish to change and select the **Inspection Mode**.

CLI syntax

The following CLI commands can be used to configure inspection and NGFW (called "policy" in the CLI) modes:

```
config system settings
  set inspection-mode {proxy | flow}
  set policy-mode {standard | ngfw}
end
```

Comparison of inspection types

The tables in this section show how different security features map to different inspection types and present the strengths and weaknesses of proxy- vs. flow-based inspection.

Security profile features mapped to inspection mode

The table below lists FortiOS security profile features and shows whether they are available in flow-based or proxy-based inspection modes.

Security Profile Feature	Flow-based inspection	Proxy-based inspection
AntiVirus	x	x
Web Filter	x	x
DNS Filter	x	x
Application Control	x	x
Intrusion Protection	x	x
Anti-Spam		x
Data Leak Protection		x
VoIP		x
ICAP		x
Web Application Firewall		x

Security Profile Feature	Flow-based inspection	Proxy-based inspection
FortiClient Profiles	x	x
Proxy Options	x	x
SSL Inspection	x	x
SSH Inspection		x
Web Rating Overrides	x	x
Web Profile Overrides		x

Individual security profile considerations

In flow mode, AntiVirus and Web Filter profiles only include flow-mode features. Web filtering and virus scanning are still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode. Application control, intrusion protection, and FortiClient profiles are not affected when switching between flow and proxy mode.

Application control uses flow-based inspection; if you apply an additional security profile to your traffic that is proxy-based, the connection will simply timeout rather than display the warning, or replacement, message. However, Application Control will still function.

Even though VoIP profiles are not available from the GUI in flow mode, the FortiGate can process VoIP traffic. In this case the appropriate session helper is used (for example, the SIP session helper).

Setting flow or proxy mode doesn't change the settings available from the CLI. However, when in flow mode you can't save security profiles that are set to proxy mode.

You can also add proxy-only security profiles to firewall policies from the CLI. So, for example, you can add a VoIP profile to a security policy that accepts VoIP traffic. This practice isn't recommended because the setting will not be visible from the GUI.

If you set flow-based to use external servers for FortiWeb and FortiMail you must use the CLI to set a Web Application Firewall profile or Anti-Spam profile to external mode and add the Web Application Firewall profile or AntiSpam profile to a firewall policy.

Proxy mode and flow mode antivirus and web filter profile options

The following tables list the antivirus and web filter profile options available in proxy and flow modes.

Antivirus features in proxy and flow mode

Feature	Proxy	Flow
Scan Mode (Quick or Full)	no	yes
Detect viruses (Block or Monitor)	yes	yes

Feature	Proxy	Flow
Inspected protocols	yes	no (all relevant protocols are inspected)
Inspection Options	yes	yes (not available for quick scan mode)
Treat Windows Executables in Email Attachments as Viruses	yes	yes
Send Files to FortiSandbox Appliance for Inspection	yes	yes
Use FortiSandbox Database	yes	yes
Include Mobile Malware Protection	yes	yes

Web filter features in proxy and flow mode

Feature	Proxy	Flow
FortiGuard category based filter	yes	yes (show, allow, monitor, block)
Category Usage Quota	yes	no
Allow users to override blocked categories (on some models)	yes	no
Search Engines	yes	no
Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex	yes	no
Restrict YouTube Access	yes	no
Log all search keywords	yes	no
Static URL Filter	yes	yes
Block invalid URLs	yes	no
URL Filter	yes	yes
Block malicious URLs discovered by FortiSandbox	yes	yes
Web Content Filter	yes	yes
Rating Options	yes	yes

Feature		Proxy	Flow
	Allow websites when a rating error occurs	yes	yes
	Rate URLs by domain and IP Address	yes	yes
	Block HTTP redirects by rating	yes	no
	Rate images by URL	yes	no
Proxy Options		yes	no
	Restrict Google account usage to specific domains	yes	no
	Provide details for blocked HTTP 4xx and 5xx errors	yes	no
	HTTP POST Action	yes	no
	Remove Java Applets	yes	no
	Remove ActiveX	yes	no
	Remove Cookies	yes	no
	Filter Per-User Black/White List	yes	no

AntiVirus scanning differences between versions of FortiOS 5.x

In FortiOS 5.0, 5.2, 5.4, 5.6 and 6.0, there are several AntiVirus (AV) scanning inspection modes available. FortiOS 5.0 includes proxy and flow-based virus scanning. FortiOS 5.2 also uses proxy-based and flow-based scanning, but the flow-based mode in FortiOS 5.2 uses a new approach to flow-based scanning (that is sometimes called deepflow or deep flow scanning). FortiOS 5.4 and onward offer another flow-based mode, quick mode, to inspect traffic efficiently.

The databases used for AV scanning does not change from proxy to flow mode unless quick mode is enabled. In flow-based quick mode, a compact antivirus database is used.

AntiVirus scanning examines files in HTTP, HTTPS, email, and FTP traffic for threats as they pass through your FortiGate. If the traffic contains compressed files, they are also examined. Go to the SysAdmin Note on the Fortinet Cookbook site for detailed information on [supported compression formats](#) in antivirus scanning.

If the AV scanner finds a threat such as a virus or some other malware, FortiOS protects your network by blocking the file.

FortiOS includes a number of AntiVirus features that make virus scanning more user-friendly. One of these features, called replacement messages, sends a customizable message to anyone whose file is blocked by AV scanning, to explain what happened and why. Other features make communication between the client and the server more seamless. The availability of these changes depending on the inspection mode.

Proxy-based AV scanning

Proxy-based AV scanning is the most feature-rich AV scanning mode. This mode uses a proxy to manage the communication between client and server. The proxy extracts content packets from the data stream as they arrive and buffers the content until the complete file is assembled. Once the file is whole, the AV scanner examines the file for threats. If no threats are found, the file is sent to its destination. If a threat is found, the file is blocked.

Because proxy-based scanning is applied to complete files, including compressed files, it provides very effective threat detection. Proxy-based scanning also supports a full range of features, including replacement messages and client comforting, making proxy-based scanning the most user friendly inspection mode. In addition the proxy manages the communication between the client and the server, improving the user experience. For example, in flow mode if a virus is found, the last part of the file is not downloaded and the connection just times out and the user cannot tell what is going on. In proxy mode, the users gets a message about the file being blocked.

Proxy-based scanning inspects all files under the oversized threshold. Since the FortiGate unit has a limited amount of memory, files larger than a certain size do not fit within the memory buffer. The default buffer size is 10 MB. You can use the `uncompssize limit` CLI command to adjust the size of this memory buffer. Files larger than the threshold are passed to the destination without scanning. You can use the **Oversized File/Email** setting in **Security Profiles > Proxy Options** to block files larger than the antivirus buffer if allowing files that are too large to be scanned is an unacceptable security risk.

During the buffering and scanning procedure, the client must wait. With a default configuration, the file is released to the client only after it is scanned. You can enable client comforting in the **Proxy Options** security profile to feed the client a trickle of data to prevent them from possibly thinking the transfer is stalled and consequently canceling the download.

Flow-based AV scanning

Although the name "flow-based scanning" is used in FortiOS 5.0, 5.2, 5.4, and 5.6, the different versions handle this mode in very different ways.

Flow AV in FortiOS 5.4 and 5.6

In FortiOS 5.4 and 5.6, there are two modes available for flow-based virus scanning: **Quick** and **Full** scan mode. Full mode is the same as flow-based scanning in FortiOS 5.2 (see below). Quick mode uses a compact antivirus database and advanced techniques to improve performance. You can designate quick or full scan mode when configuring the antivirus profile in the GUI. Alternatively, use the following CLI command to enable quick or full mode:

```
config antivirus profile
edit <profile>
set scan-mode {quick | full}
end
```

Flow AV in FortiOS 5.2 (deepflow or deep flow)

FortiOS 5.2 introduced a new type of flow-based AV scanning, that is sometimes called deepflow or deep flow, and that takes a hybrid approach where content packets are buffered while simultaneously being sent to their destination. When all of the files packets have been collected and buffered, but before the final packet is delivered, the buffered file is scanned. If a threat is found, the last packet is blocked and the client application has to deal with not getting the completed file. If no threat is found the final packet is sent and the user gets their file.

Deepflow AV scanning is as good as proxy-based AV scanning at detecting threats. There may be a small performance advantage over proxy-based AV as files get larger based on the difference between sending the

whole file after analysis and just sending the last packet. Deepflow's most notable limitation is that, just like the flow-based AV in 5.0, it does not support many of the user-friendly features provided by proxy-based AV.

Flow AV in FortiOS 5.0

In FortiOS 5.0, flow-based AV scanning examines the content of individual data packets as they pass through the FortiGate. There is no proxy involved so packets are not changed by the proxy and files are not buffered for analysis. Potentially less memory and CPU resources are used, resulting in a potential performance increase compared to using proxy-based mode. FortiOS 5.0 flow-based AV scanning is also not limited by file size.

Flow AV uses the IPS engine and the AV database and is effective at many kinds of threat detection; however, because it can only analyze what is in an individual packet rather than a complete file, flow-based scanning cannot detect some types of malware, including polymorphic code. Malware in documents, compressed files, and some archives are also less likely to be detected.

Flow AV does not actually block files, it stops delivering a file's packets once a threat has been detected. This means that parts of the file may already have been delivered when the threat has been detected and the recipient application is responsible for dealing with the partially complete content.

In addition flow AV can be less user friendly. Replacement messages are not supported and clients may have to wait for sessions to time out without knowing why content has been blocked.

AntiVirus

This section describes how to configure the antivirus options. From an antivirus profile you can configure the FortiGate unit to apply antivirus protection to HTTP, FTP, IMAP, POP3, SMTP, and NNTP sessions. If your FortiGate unit supports SSL/SSH content scanning and inspection, you can also configure antivirus protection for HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions.

In many cases you can just customize the default antivirus profile and apply it to the security policy that accepts the traffic to be virus scanned. You can also create custom antivirus profiles if want to apply different types of virus protection to different traffic.

This Handbook chapter includes [Inside FortiOS: AntiVirus](#) providing readers an overview of the features and benefits of key FortiOS components.

For readers needing to delve into greater detail, we provide the following topics:

- [Antivirus concepts](#)
- [Enabling AntiVirus scanning](#)
- [Testing your antivirus configuration](#)
- [Example Scenarios](#)

Antivirus concepts

The word “antivirus” refers to a group of features that are designed to prevent unwanted and potentially malicious files from entering your network. These features all work in different ways, which include checking for a file size, name, or type, or for the presence of a virus or grayware signature.

The antivirus scanning routines your FortiGate unit uses are designed to share access to the network traffic. This way, each individual feature does not have to examine the network traffic as a separate operation, and the overhead is reduced significantly. For example, if you enable file filtering and virus scanning, the resources used to complete these tasks are only slightly greater than enabling virus scanning alone. Two features do not require twice the resources.

Antivirus scanning examines files for viruses, worms, trojans, and other malware. The antivirus scan engine has a database of virus signatures it uses to identify infections. If the scanner finds a signature in a file, it determines that the file is infected and takes the appropriate action.

Malware threats

Malware is the general term covering all the different types of threats to your computer safety such as:

- [Viruses](#)
- [Worms](#)
- [Trojan horses](#)
- [Ransomware](#)
- [Scareware](#)
- [Spyware](#)
- [Adware](#)
- [Botnets](#)

- [Phishing](#)
- [Grayware](#)

Viruses

Viruses are self-replicating code that install copies of themselves into other programs or data files for boot sectors of storage devices. Viruses can often carry a “payload” which performs some undesirable function. These functions can include but are not limited to:

- Stealing drive space
- Stealing CPU cycles
- Accessing private information
- Corrupting data
- Digital defacement or vandalism
- Spamming contact lists

Worms

A worm is a piece of standalone computer code that replicates itself in order to spread to other computers. It normally uses a computer network to spread itself, using security vulnerabilities on the target computer or network to propagate. Unlike a virus, it does not attach itself to an existing file. Even if there is no payload, worms consume resources such as bandwidth and storage space just through their act of replication.

Trojan horses

A Trojan horse, or Trojan is malware that is defined by its delivery method. Through the use of social engineering, or some other method, the code is installed on a system by a valid user of the system and like the original Trojan horse there is something more than advertised within the software. Trojans, unlike worms or viruses are generally non-self-replicating. The most common payload of a Trojan is the setting up of a “backdoor” control mechanism to the system that it is installed on.

Ransomware

Ransomware is a type of malware that, as the name implies, hold the system ransom until payment of some kind is made. It does this by restricting access to the legitimate owner of the system either by encrypting files or locking the system. Usually, a message of some kind is displayed with the demands. Upon payment a utility or key is sent to the user to unlock the system.

Scareware

Scareware comes in two main flavours; the first tries to convince the user that his computer is infected with some non-existent malware, scaring the user into purchasing the author’s virus removal utility. The utility is nonfunctional or some additional form of malware.

The second form tries to convince the user that the computer has been or is being used for an illegal act, such as being part of a botnet or storing child pornography. Again, the objective is to scare the user into paying to cure something that is not really there.

Spyware

Spyware is used by its authors to collect information about the user and its computer without the user's knowledge. The end result can be as benign as being better able to target ads, to as criminal as key loggers designed to record account ids and passwords of bank accounts and forward them off to the authors.

Adware

Adware is not malware per se. It is merely any software that produces advertisements in order to generate revenue for its author. While a lot of people find this inconvenient or irritating, it is not malware. As such, it is not blocked by the antivirus software for being malware.

Software that has adware built into it will be blocked if it has malware in it.

Botnets

A botnet is a network of Internet connected computers that have been covertly usurped to forward transmissions to other computers on the Internet on behalf of a "master". These transmissions can be minimally damaging, such as spam, or they can critically impact a target as when used to launch a Distributed Denial of Service attack.

Any such computer is referred to as a zombie - in effect, a computer "robot" or "bot" that serves the wishes of some master spam or virus originator. Most computers compromised in this way are home-based.

According to a report from Russian-based Kaspersky Labs, botnets -- not spam, viruses, or worms -- currently pose the biggest threat to the Internet. A report from Symantec came to a similar conclusion.

See also: [Botnet protection](#).

Phishing

Phishing is a social engineering technique that is used to obtain sensitive and confidential information by masquerading as a communication from a trusted entity such as a well-known institution, company, or website. Usually, the malware is not in the communication itself but in the links within the communication.

Grayware

Grayware programs are unsolicited software programs installed on computers, often without the user's consent or knowledge. Grayware programs are generally considered an annoyance, but they can also cause system performance problems or be used for malicious purposes.

AntiVirus scanning order

The antivirus scanning function includes various modules and engines that perform separate tasks.

FortiOS has two different modes of antivirus scanning: **proxy-based** and **flow-based**. The reasons for the different modes are performance and granularity. In just about everything relating to security there is a constant balancing act going on. As the level of security and comprehensiveness increases, there is by necessity a decrease in either convenience or performance or both. The increase in processing to scan for more threats requires more resources; resources that are a finite supply on the hardware. Granularity can sometimes be used to mitigate performance impact by scanning for a smaller subset of traffic but this is only recommended when that smaller subset of traffic is the only traffic going through the firewall.

If the traffic on the device is slight, then the impact on the performance will hardly be noticeable. But if the unit is working close to capacity in terms of traffic and there are a lot of files coming through, then there might be a noticeable decline in the performance.

While both modes offer significant security, proxy-based is weighted towards being more thorough and easily configurable, while flow-based is designed to optimize performance.

See [Antivirus scanning differences in FortiOS 5.0, 5.2, 5.4, and 5.6](#) in the [Inspection Modes](#) section for more details on flow vs. proxy inspection modes on your FortiGate.

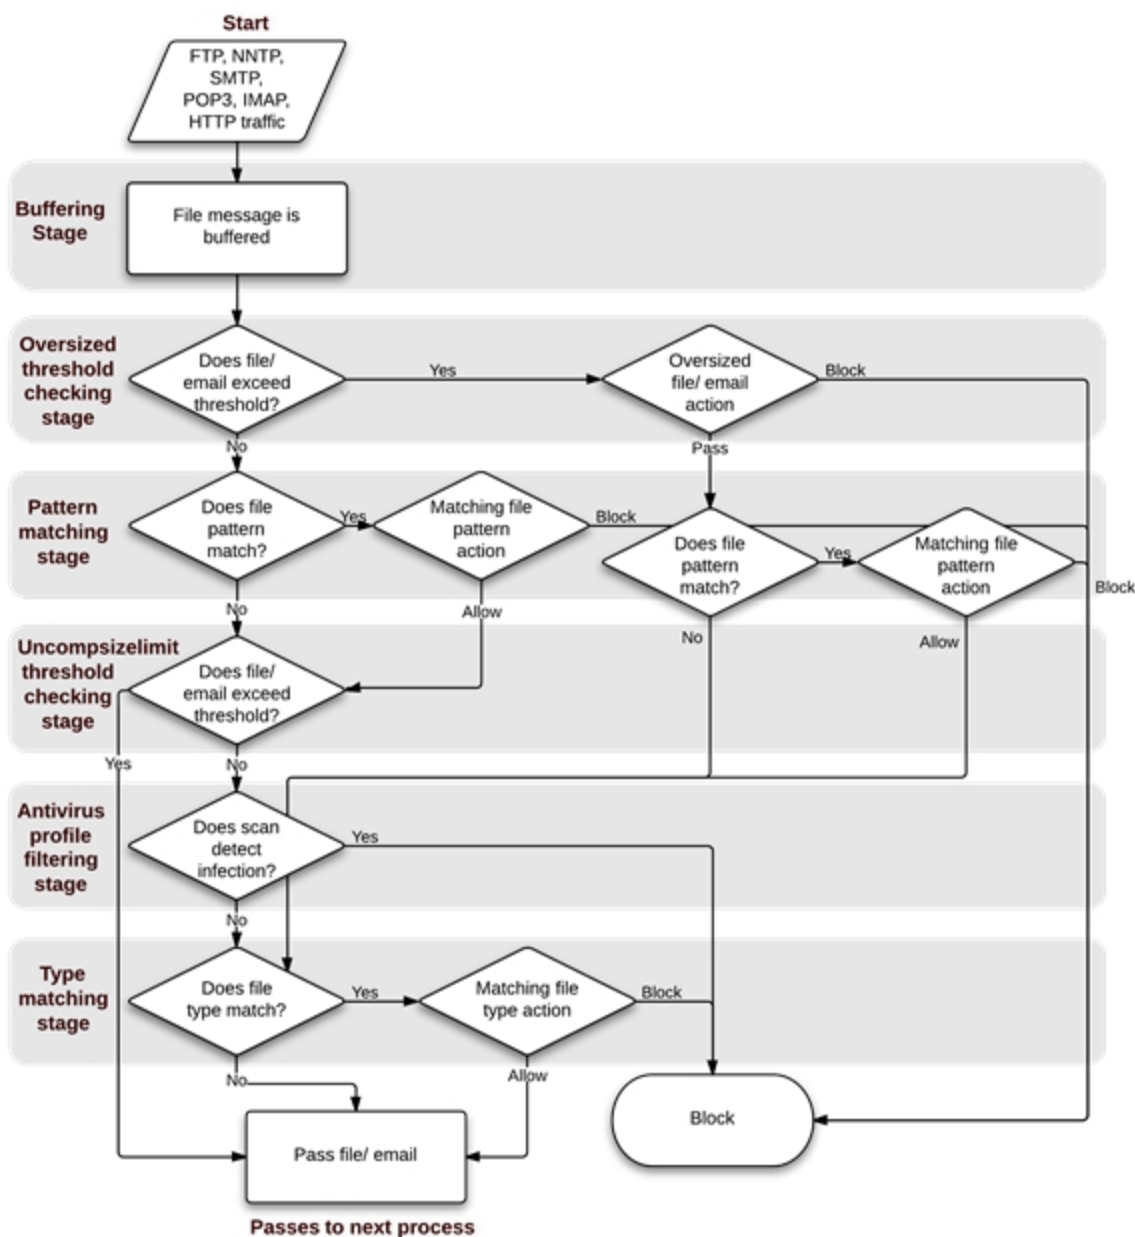

Proxy-based antivirus scanning order

The following figure illustrates the antivirus scanning order when using proxy-based scanning. The first check for oversized files/email is to determine whether the file exceeds the configured size threshold. The `uncompsizelimit` check is to determine if the file can be buffered for file type and antivirus scanning. If the file is too large for the buffer, it is allowed to pass without being scanned. For more information, see the `config antivirus service` command. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics, if enabled.

File filtering includes file pattern and file type scans which are applied at different stages in the antivirus process.

Antivirus scanning order when using the normal, extended, or extreme database

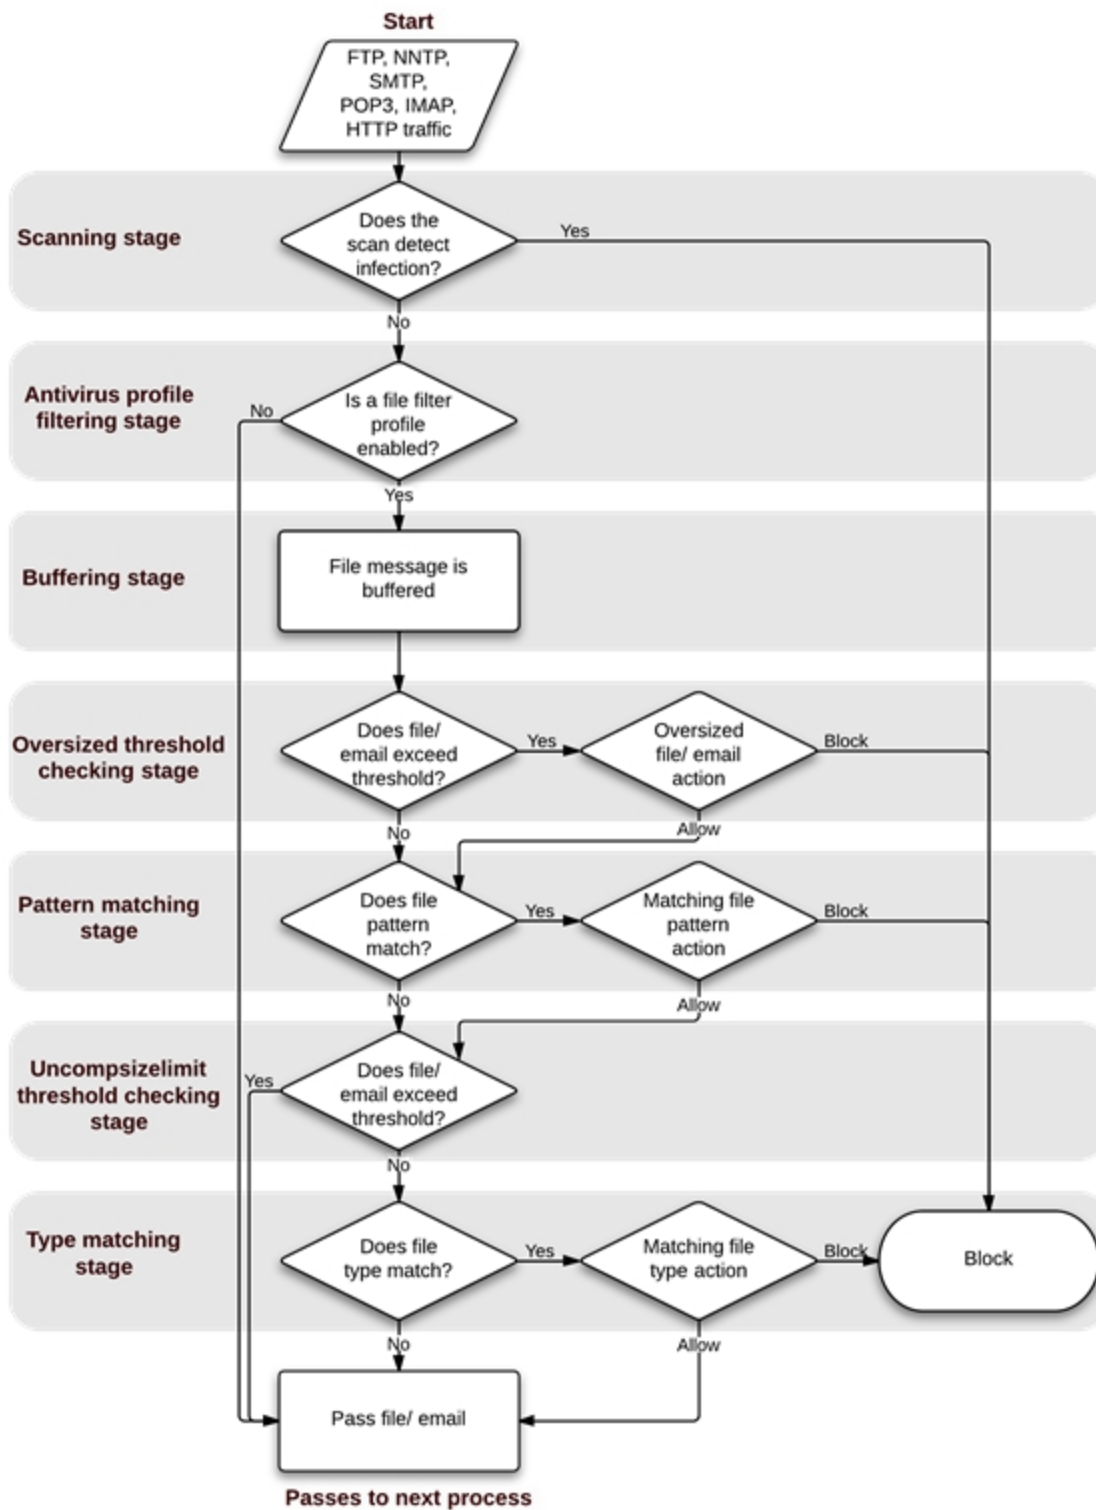

If a file fails any of the tasks of the antivirus scan, no further scans are performed. For example, if the file `fakefile.EXE` is recognized as a blocked file pattern, the FortiGate unit will send the end user a replacement message, and delete or quarantine the file. The unit will not perform virus scan, grayware, heuristics, and file type scans because the previous checks have already determined that the file is a threat and have dealt with it.

Flow-based antivirus scanning order

The following figure illustrates the antivirus scanning order when using flow-based scanning (i.e. the flow-based database). The antivirus scan takes place before any other antivirus-related scan. If file filter is not enabled, the

file is not buffered. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics if they are enabled.

AntiVirus databases

The antivirus scanning engine relies on a database of virus signatures to detail the unique attributes of each infection. The antivirus scan searches for these signatures, and when one is discovered, the FortiGate unit determines the file is infected and takes action.

All FortiGate units have the normal antivirus signature database but some models have additional databases you can select for use. Which you choose depends on your network and security needs.

Normal	Includes viruses currently spreading as determined by the FortiGuard Global Security Research Team. These viruses are the greatest threat. The Normal database is the default selection and it is available on every FortiGate unit.
Extended	Includes the normal database in addition to recent viruses that are no-longer active. These viruses may have been spreading within the last year but have since nearly or completely disappeared.
Extreme	Includes the extended database in addition to a large collection of 'zoo' viruses. These are viruses that have not spread in a long time and are largely dormant today. Some zoo viruses may rely on operating systems and hardware that are no longer widely used.

If your FortiGate unit supports extended, extreme, or flow-based virus database definitions, you can select the virus database most suited to your needs.

If you require the most comprehensive antivirus protection, enable the extended virus database. The additional coverage comes at a cost, however, because the extra processing requires additional resources.

To change the antivirus database

Use the CLI to run the following commands:

```
config antivirus settings
    set default-db extended
end
```

AntiVirus techniques

The first three antivirus features in the list below work in sequence to efficiently scan incoming files and offer your network optimal antivirus protection. The first two features have specific functions, the third, heuristics, protects against new or previously unknown virus threats.

- **Virus scan**

If the file passes the file pattern scan, the FortiGate unit applies a virus scan to it. The virus definitions are kept up-to-date through the FortiGuard Distribution Network (FDN).

- **Grayware protection**

If the file passes the virus scan, it can be checked for grayware. Grayware scanning is an optional function and must be enabled in the CLI if it is to be scanned for along with other malware. Grayware cannot be scanned for on

its own. While done as a separate step, antivirus scanning must be enabled as well.

To enable grayware detection enter the following in the CLI:

```
config antivirus settings
  set grayware enable
end
```

To disable grayware detection enter the following in the CLI:

```
config antivirus settings
  set grayware disable
end
```

Grayware signatures are kept up to date in the same manner as the antivirus definitions.

• Heuristics

After an incoming file has passed the grayware scan, it is subjected to the heuristics scan. The FortiGate heuristic antivirus engine, if enabled, performs tests on the file to detect virus-like behavior or known virus indicators. In this way, heuristic scanning may detect new viruses, but may also produce some false positive results. You configure heuristics from the CLI.

To set heuristics, enter the following in the CLI:

```
config antivirus heuristic
  set mode {pass | block |disable}
end
```

- “block” enables heuristics and any files determined to be malware are blocked from entering the network.
- “pass” enables heuristics but any files determined to be malware are still allowed to pass through to the recipient.
- “disable” turns off heuristics.

• FortiGuard AntiVirus

The FortiGuard Antivirus services are included in the regular FortiGuard subscription and include automatic updates of antivirus engines and definitions as well as a DNS black list (DNSBL) through the FortiGuard Distribution Network (FDN).

Current information about your subscription and version numbers can be found at **System > FortiGuard**. This page will also allow the configuration of connections to the FortiGuard Center and how often to check for updates to the antivirus files.

Updating antivirus definitions can cause a short disruption of traffic being scanned while the FortiGate unit applies the new signature database. Schedule updates for time periods when traffic is light to minimize disruption.

• Botnet protection

A botnet is a network of Internet connected computers that have been covertly usurped to forward transmissions to other computers on the Internet on behalf of a “master”. These transmissions can be minimally damaging, such as spam, or they can critically impact a target as when used to launch a Distributed Denial of Service attack.

Any such computer is referred to as a zombie - in effect, a computer “robot” or “bot” that serves the wishes of some master spam or virus originator. Most computers compromised in this way are home-based.

The latest botnet database is available from FortiGuard. To see the version of the database and display its contents, go to **System > FortiGuard > AntiVirus >** and you will see data for **Botnet IPs** and **Botnet Domains**. You can also block, monitor, or allow outgoing connections to botnet sites for each FortiGate interface.

• Quarantine / Source IP ban

As of FortiOS 5.2, quarantine was a place where traffic content was held in storage where it couldn't interact with the network or system. This was removed, but the term quarantine was kept to describe keeping selected source IPs from interacting with the network and protected systems. This source IP ban is kept in the kernel rather than in any specific application engine and can be queried by APIs. The features that can use the APIs to access and use the banned source IP addresses are antivirus, DLP, DoS and IPS. Both IPv4 and IPv6 version are included in this feature.

You quarantine a source address through the GUI. Go to **FortiView > Sources**. Right-click on the source address you wish to quarantine and select **Quarantine Source Address**. You can set the duration of the quarantine in days, hours, minutes, or seconds. A User Quarantine ban can be removed in **Monitor > User Quarantine Monitor**.

To configure the AntiVirus security profile to add the source IP address of an infected file to the quarantine or list of banned source IP addresses in the CLI:

```
config antivirus profile
  edit <name of profile>
    config nac-quar
      set infected quar-src-ip
      set expiry 5m
    end
```

If the `quar-src-ip` action is used, the additional variable of expiry time will become available. This variable determines for how long the source IP address will be blocked. In the CLI the option is called `expiry` and the duration is in the format `<###d##h##m>`. The maximum days value is 364. The maximum hour value is 23 and the maximum minute value is 59. The default is 5 minutes.

FortiGuard AntiVirus updates

To ensure that your system receives the most protection available, all virus definitions and signatures are updated regularly through the FortiGuard AntiVirus services. To configure this feature, go to **System > FortiGuard**. Under **AntiVirus & IPS Updates**, enable **Scheduled Updates**. From here you can schedule updates to occur on a consistent weekly, daily, or even hourly basis.

Updating antivirus definitions can cause a short disruption of traffic being scanned while the FortiGate unit applies the new signature database. Schedule updates for time periods when traffic is light to minimize disruption.

FortiSandbox

Not every piece of malware has a signature. This is especially true of new malware and variations on existing malware. FortiOS can upload suspicious files to FortiSandbox for sandbox inspection. When a FortiGate uses sandbox inspection, files are sent to the FortiSandbox. Then the FortiSandbox uses virtual machines (VMs)

running different operating systems to test the file, to determine if it is malicious. If the file exhibits risky behavior, or is found to contain a virus, a new signature can be added to both the local FortiGate malware database and the FortiGuard AntiVirus signature database.

A file is deemed suspicious when it does not contain a known threat but has characteristics that suggest it may be malware. The characteristics that determine if a file is suspicious are updated by Fortinet to reflect the current threat climate.

FortiSandbox is available as a physical or virtual appliance (FortiSandbox Appliance), or as a cloud advanced threat protection service integrated with FortiGate (FortiCloud).

To configure an AntiVirus profile to send files to FortiSandbox, first verify that your FortiSandbox appliance is configured or that your FortiCloud account is active. Then go to **Security Profiles > AntiVirus** and enter the desired **Inspection Options**.

Sending files to the FortiSandbox appliance or to FortiSandbox Cloud does not block files immediately. Instead, the files assist in the discovery of new threats and the creation of new signatures to be added to the global FortiGuard AntiVirus database. Files deemed malicious are also immediately added to a custom Malware Package which is downloaded by the FortiGate every two minutes for live detection.

The **Advanced Threat Protection Statistics** dashboard widget displays the number of files that your FortiGate unit has uploaded or submitted to FortiSandbox. To see FortiSandbox statistics for the last 7 days, go to **Fortinet Security Fabric > Settings**.

Option for "Suspicious Files Only" for FortiSandbox submissions

Beginning in FortiOS 6.0.1, FortiGates can use the FortiSandbox Cloud service as part of the AntiVirus subscription. In order to reduce client upload bandwidth usage and general load on the FortiSandbox service, a new "Suspicious Files Only" upload option has been added to the AntiVirus profile, which previously only had "None" and "All Supported Files".

In order to enforce best practices, "None" is now the default.

Syntax

```
config antivirus profile
  edit <profile name>
    set ftgd-analytics [disable|suspicious|everything]
  end
```

Client comforting

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit scans it. If no infection is found, the file is sent along to the client. The client initiates the file transfer and nothing happens until the FortiGate finds the file clean, and releases it. Users can be impatient, and if the file is large or the download slow, they may cancel the download, not realizing that the transfer is in progress.

The client comforting feature solves this problem by allowing a trickle of data to flow to the client so they can see the file is being transferred. The default client comforting transfer rate sends one byte of data to the client every ten seconds. This slow transfer continues while the FortiGate unit buffers the file and scans it. If the file is infection-free, it is released and the client will receive the remainder of the transfer at full speed. If the file is infected, the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned and potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Enable and configure client comforting

1. Go to **Security Profiles > Proxy Options**.
2. Select a Proxy Options profile and choose **Edit**, or select **Create New** to make a new one.
3. Scroll down to the **Common Options** section and enable the **Comfort Clients** feature. This will set the option on all of the applicable protocols. The ability to set this feature on a protocol by protocol basis exists in the CLI.
4. Select **OK** or **Apply** to save the changes.
5. Apply this Proxy Options profile in any security policy for it to take effect on all traffic handled by the policy.

The default values for Interval and Amount are 10 and 1, respectively. This means that when client comforting takes effect, 1 byte of the file is sent to the client every 10 seconds. You can change these values to vary the amount and frequency of the data transferred by client comforting.

Oversized files and emails

Downloaded files can range from a few Kilobytes to multiple Gigabytes. A FortiGate doesn't have the memory to allow for a large number of people downloading large files. Imagine the memory required for a team of developers to all download the latest Linux OS distribution at once, in addition to the normal requirements of the firewall. Everything would come to a grinding halt if the FortiGate tried to store each of those Gigabyte+ files in memory. To give you some piece of mind, the chances of malware being in a large file like those is much smaller than in a smaller single Megabyte file, so the threat is somewhat limited, but you will probably want to use your computers antivirus software to scan those large files after they have been downloaded.

A threshold must be set to prevent the resources of the system from becoming overloaded. By default the threshold is 10 MB. Any files larger than the threshold will not be scanned for malware. With a maximum file size threshold in place, it must now be determined what is to be done with the files that are larger than threshold. There are only 2 choices; either the file is passed through without being scanned for malware or the file is blocked. The default action for oversized files is to pass them through.

If you wish to block the downloading of files over the threshold, this can be set within the Proxy Option profile found at **Security Profiles > Proxy Options**, under **Common Options**.

Enable **Block Oversized File/Email**.

This will reveal an additional option, **Threshold (MB)**. The threshold of the files is set based upon the protocol being used to transfer the file. In the CLI and configuration file, the threshold variable is found in each of the protocol sections within the profile. Changing the value in this field will change the `oversize-limit` value for all of the protocols.

If you wish to change the `oversize-limit` value on the protocols covered in a Proxy Option profile you have two options.

1. You can go into the CLI and change the value manually within each of the protocol sections.
2. You can use the GUI to temporarily block oversized files, and when configuring it change the threshold to the new value that you want. Apply this setting. Then go back to the profile and turn off the block setting. If you now go into the CLI you will find that the configuration file has retained the new oversize-limit value.

The settings can be found in the CLI by going to:

```
config firewall profile-protocol-options
  edit <profile_name>
    config <protocol>
      set oversize-limit <size_int>
    end
  end
end
```

Archive scan depth

The antivirus scanner will open archives and scan the files inside. Archives within other archives, or nested archives, are also scanned to a default depth of twelve nestings. You can adjust the number of nested archives the FortiGate unit will scan with the `uncompressed-nest-limit` CLI command. Further, the limit is configured separately for each traffic type.

Configuring archive scan depth

For example, this CLI command sets the archive scan depth for SMTP traffic to 5. That is, archives within archives will be scanned five levels deep.

```
config firewall profile-protocol-options
  edit "default"
    config http
      set uncompressed-nest-limit 5
    end
  end
end
```

You can set the nesting limit from 2 to 100.

Scan buffer size

When checking files for viruses, there is a maximum file size that can be buffered. Files larger than this size are passed without scanning. The default size for all FortiGate models is 10 megabytes.

Archived files are extracted and email attachments are decoded before the FortiGate unit determines if they can fit in the scan buffer. For example, a 7 megabyte ZIP file containing a 12 megabyte EXE file will be passed without scanning with the default buffer size. Although the archive would fit within the buffer, the uncompressed file size will not.

Configuring the uncompression buffer

In this example, the `uncompressed-oversize-limit` CLI command is used to change the scan buffer size to 20 megabytes for files found in HTTP traffic:

```
config firewall profile-protocol-options
  edit <profile_name>
    config http
      set uncompressed-oversize-limit 20
    end
  end
```

```
end
end
```

The maximum buffer size varies by model. Enter `set uncompressed-oversize-limit ?` to display the buffer size range for your FortiGate unit.

Windows file sharing (CIFS)

FortiOS supports virus scanning of Windows file sharing traffic. This includes CIFS, SMB, and SAMBA traffic. This feature is applied by enabling SMB scanning in an antivirus profile and then adding this profile to a security policy that accepts CIFS traffic. CIFS virus scanning is available only through flow-based antivirus scanning.

FortiOS flow-based virus scanning can detect the same number of viruses in CIFS/SMB/SAMBA traffic as it can for all supported content protocols.

Note the following about CIFS/SMB/SAMBA virus scanning:

- Some newer version of SAMBA clients and SMB2 can spread one file across multiple sessions, preventing some viruses from being detected if this occurs.
- Enabling CIFS/SMB/SAMBA virus scanning can affect FortiGate performance.
- SMB2 is a new version of SMB that was first partially implemented in Windows Vista.
- Currently SMB2 is supported by Windows Vista or later, and partly supported by Samba 3.5 and fully support by Samba 3.6.
- The latest version of SMB2.2 will be introduced with Windows 8.
- Most clients still use SMB as default setting.

Configuring CIFS/SMB/SAMBA virus scanning

Use the following command to enable CIFS/SMB/SAMBA virus scanning in an antivirus profile:

```
config antivirus profile
edit <smb-profile>
config smb
set options scan
end
```

Then add this antivirus profile to a security policy that accepts the traffic to be virus scanned. In the security policy the service can be set to ANY, SAMBA, or SMB.

```
config firewall policy
edit <policy-id-integer>
set service ANY
...
set utm-status enable
set av-profile <smb-profile>
end
```

Enabling AntiVirus scanning

Antivirus scanning is configured in an AntiVirus profile, but it is enabled in a firewall policy. Once the use of an AntiVirus profile is enabled and selected in one or more firewall policies, all the traffic controlled by those firewall policies will be scanned according to the settings in that profile.

By going to **System > Feature Visibility**, you can enable or disable two aspects of the AntiVirus Profile.

1. **AntiVirus** will determine if the option to use AntiVirus profiles is available.
2. **Multiple Security Profiles** will determine if you can configure any AntiVirus profiles beyond the default profile.

The use of antivirus protection is a minimum standard for security protection. The question left to decide is whether or not you wish to use multiple profiles in your configuration.

From **Security Profiles > AntiVirus** you can edit existing profiles or create and configure new antivirus profiles that can then be applied to firewall policies. A profile is specific configuration information that defines how the traffic within a firewall policy is examined and what action may be taken based on the examination.

The configuration of the antivirus profile depends on whether the inspection mode is proxy-based or flow-based. You select the inspection mode by going to the **System > Settings** page. The FortiGate's inspection mode is also displayed on the unit's **Dashboard** in the **System Information** widget.

The discussion of the [differences in antivirus scanning modes](#) helps to understand how this scanning works in proxy- and flow-based inspection, as well as in different versions of FortiOS 5.x.

Enabling AntiVirus in Proxy-mode - GUI

1. Go to **Security Profiles > AntiVirus**.
2. Choose whether you want to edit an existing profile or create a new one.
 - The default profile will be the one displayed by default.
 - If you are going to edit an existing profile, selecting it can be done by either using the drop down menu in the upper right hand corner of the window or by selecting the List icon (the furthest right of the 3 icons in the upper right of the window, if resembles a page with some lines on it), and then selecting the profile you want to edit from the list.
 - If you need to create a new profile you can either select the **Create New** icon (a plus sign within a circle) or select the **List icon** and then select the **Create New** link in the upper left of the window that appears.
3. If you are creating a new profile, write a name for it in the **Name** field.
4. For the **Detect Viruses** field, select either **Block** to prevent infected files from passing throughout the FortiGate or **Monitor** to allow infected files to pass through the FortiGate but to record instances of infection.
5. Under **Inspected Protocols**, enable the protocols you wish to be blocked or monitored.
6. Under **APT Protection Options**, you may enable the following: **Content Disarm and Reconstruction**, **Treat Windows Executables in Email Attachments as Viruses** and **Send Files to FortiSandbox Cloud for Inspection**, and **Use Virus Outbreak Prevention Database**.

FortiSandbox options are only available if you have a FortiCloud account active on your FortiGate.

7. Select **Apply**.
8. Add the AntiVirus profile to a firewall security policy.

To view Mobile Malware license and version information, go to **System > FortiGuard** and locate the Mobile Malware section in the **License Information** table.

Content Disarm and Reconstruction (CDR)

Content Disarm and Reconstruction (CDR) is used to remove exploitable content and replace it with content that is known to be safe. As the files are processed through an enabled Proxy-based AntiVirus profile, content that is deemed malicious or unsafe is replaced with content that will allow the traffic to continue, but not put the recipient at risk.

Content that can be scanned includes PDF and Microsoft Office files leaving the network on CDR-supported protocols (HTTP web download, SMTP email send, IMAP/POP3 email retrieval—MAPI is not supported).

This feature will work without FortiSandbox configured, but only if you wish to discard the original file. If FortiSandbox is configured and it responds that the file is clean, it will pass the content unmodified.

This feature will not work if `splice` or `client-comfort` are enabled under `profile-protocol-options` for SMTP.

CDR does not alter documents in an HTTP POST, and is not designed to strip content leaving the network for HTTP. It only works on HTTP GET.

Syntax

The use of CDR is enabled or disabled separately for each protocol in the profile. Note that all CDR commands are only available when you set the profile's `inspection-mode` to `proxy`.

```
config antivirus profile
  edit <name>
    set inspection-mode proxy
    config <protocol>
      set options scan
      set content-disarm {enable | disable}
    next
  end
end
```

You must ensure that `set options scan` is configured.

If `set options av-monitor` is configured for a protocol, it will enable the `detect-only` option (see below) and CDR will not occur for that protocol.

The enabling and disabling of the CDR is specific to the protocol, but the granular configuration of which types of content will be rewritten by the CDR engine are configured based on the AntiVirus profile. The settings within the `config content-disarm` context are applicable to all of the CDR enabled protocols.

```
config antivirus profile
  edit <name>
    config content-disarm
      set original-file-destination {fortisandbox | quarantine | discard}
      set office-macro {enable | disable}
      set office-hylink {enable | disable}
      set office-linked {enable | disable}
      set office-embed {enable | disable}
      set pdf-javacode {enable | disable}
      set pdf-embedfile {enable | disable}
      set pdf-act-gotor {enable | disable}
      set pdf-act-launch {enable | disable}
      set pdf-act-uri {enable | disable}
      set pdf-act-sound {enable | disable}
      set pdf-act-movie {enable | disable}
      set pdf-act-java {enable | disable}
      set pdf-act-form {enable | disable}
      set cover-page {enable | disable}
      set detect-only {enable | disable}
    next
  end
end
```

Where:

Option	Description
<code>original-file-destination</code>	Select the destination to which files will be sent for inspection. Note that, once you enable <code>content-disarm</code> under a protocol, you will be warned that all original files will be discarded. To be able to retrieve the original files, you must set an <code>original-file-destination</code> for this profile.
<code>office-macro</code>	Enables/disables stripping of macros in Microsoft Office documents.
<code>office-hylink</code>	Enables/disables stripping of hyperlinks in Microsoft Office documents.
<code>office-linked</code>	Enables/disables stripping of linked objects in Microsoft Office documents.
<code>office-embed</code>	Enables/disables stripping of embedded objects in Microsoft Office documents.
<code>pdf-javacode</code>	Enables/disables stripping of JavaScript code in PDF documents.
<code>pdf-embedfile</code>	Enables/disables stripping of embedded files in PDF documents.
<code>pdf-act-gotor</code>	Enables/disables stripping of links to other PDFs in PDF documents.
<code>pdf-act-launch</code>	Enables/disables stripping of links to external applications in PDF documents.
<code>pdf-act-uri</code>	Enables/disables stripping of links to URI resources in PDF documents.
<code>pdf-act-sound</code>	Enables/disables stripping of embedded sound files in PDF documents.
<code>pdf-act-movie</code>	Enables/disables stripping of embedded movies in PDF documents.
<code>pdf-act-java</code>	Enables/disables stripping of actions that execute JavaScript code in PDF documents.
<code>pdf-act-form</code>	Enables/disables stripping of actions that submit data to other targets in PDF documents.
<code>cover-page</code>	Enables/disables inserting a cover page into the disarmed document.
<code>detect-only</code>	Enables/disables only detect disarmable files, do not alter content.

When the antivirus profile successfully detects suspicious content and strips the data, a new page is appended to the start of the document with a message that reads *"This file has been cleaned of potential threats"*.

You can set `cover-page disable` (see above) if you do not want a cover page appended to any disarmed content.

FortiGuard virus outbreak prevention

FortiGuard virus outbreak prevention uses checksums to filter files in order to detect and prevent quick virus outbreaks, because it usually takes at least a few hours for FortiGuard to develop and push signatures and a virus outbreak can do a lot of damage within that time period. This method proves to be quite effective using hash values of probable virus files.

Enable this feature under **Security Profiles > AntiVirus > Use Virus Outbreak Prevention Database**. Note that this feature requires a license, which you can obtain through **System > FortiGuard > Outbreak Prevention**.

Syntax

Note that `outbreak-prevention` is only available when `options` is set to `scan`:

```
config antivirus profile
  edit <name>
    config <protocol>
      set options scan
      set outbreak-prevention {disabled | files | full-archive}
    next
  ...
```

where `full-archive` analyzes files including the contents of archives, as opposed to `files` which does not include the contents of archives.

Enabling AntiVirus in Flow-mode - GUI

1. Go to **Security Profiles > AntiVirus**.
2. Choose whether you want to edit an existing profile or create a new one.
 - The default profile will be the one displayed by default.
 - If you are going to edit an existing profile, selecting it can be done by either using the drop down menu in the upper right hand corner of the window or by selecting the List icon (the furthest right of the 3 icons in the upper right of the window, if resembles a page with some lines on it), and then selecting the profile you want to edit from the list.
 - If you need to create a new profile you can either select the **Create New** icon (a plus sign within a circle) or select the **List icon** and then select the **Create New** link in the upper left of the window that appears.
3. If you are creating a new profile, write a name for it in the **Name** field.
4. Select **Quick** or **Full Scan Mode**(see the discussion of the [differences in antivirus scanning modes](#) for more information).
5. For the **Detect Viruses** field, select either **Block** to prevent infected files from passing throughout the FortiGate or **Monitor** to allow infected files to pass through the FortiGate but to record instances of infection.
6. Under **Inspected Protocols**, enable the protocols you wish to be blocked or monitored.
7. Under **Inspection Options**, you may enable the following: **Treat Windows Executables in Email Attachments as Viruses** and **Include Mobile Malware Protection**.

You may also enable the following options if you have a FortiCloud account active on your FortiGate: **Send Files to FortiSandbox Cloud for Inspection** and **Use FortiSandbox Database**.

8. Select **OK** or **Apply**.
9. Add the AntiVirus profile to a firewall security policy.

Enabling AntiVirus - CLI

Configure the scan option for each type of traffic you want scanned.

1. Configure the AntiVirus profile

```
config antivirus profile
  edit <profile_name>
    set comment "scan and delete virus"
    set replacemsg-group ''
    set scan-botnet-connections block
    set ftgd-analytics suspicious
    config http
      set options scan
    end
    config ftp
      set options scan
    end
    config imap
      set options scan
    end
    config pop3
      set options scan
    end
    config smtp
      set options scan
    end
    config nntp
      set options scan
    end
    config smb
      set options scan
    end
  end
end
```

2. Add the AntiVirus profile to the Fortigate firewall security policy. When using the CLI, you will need to know the policy ID number.

```
config firewall policy
  edit <policy ID number>
    set av-profile <profile_name>
    set profile-protocol-options default
  end
end
```

Overriding the AV engine file scan timeout

Overriding the AV engine file scan timeout allows the FortiGate to scan files as large as 4GB without breaking the scan.

Override the large file scan timeout value in seconds (30 - 3600). Zero is the default value and is used to disable this command. When disabled, the daemon adjusts the large file scan timeout based on the file size.

Syntax

```
config antivirus settings
```

```
set override-timeout 0
end
```

Testing your antivirus configuration

You have configured your FortiGate unit to stop viruses, but you'd like to confirm your settings are correct. Even if you have a real virus, it would be dangerous to use for this purpose. An incorrect configuration will allow the virus to infect your network.

To solve this problem, the European Institute of Computer Anti-virus Research has developed a test file that allows you to test your antivirus configuration. The EICAR test file is not a virus. It cannot infect computers, nor can it spread or cause any damage. It's a very small file that contains a sequence of characters. Your FortiGate unit recognizes the EICAR test file as a virus so you can safely test your FortiGate unit antivirus configuration.

Go to <http://www.fortiguard.com/antivirus/eicartest.html> to download the test file (eicar.com) or the test file in a ZIP archive (eicar.zip).

If the antivirus profile applied to the security policy that allows you access to the Web is configured to scan HTTP traffic for viruses, any attempt to download the test file will be blocked. This indicates that you are protected.

Example scenarios

The following examples provide sample antivirus configuration scenarios.

Configuring simple default AntiVirus profile

If performance is not a real concern and the FortiGate's resources are not being stretched, it is perfectly reasonable to create one AntiVirus profile that covers the range of uses found in your environment. This example is one possible default configuration.

Context:

- This is an edited default profile and will be used on all security policies
- It will need to scan for malware on all available protocols.
- Malware, botnets, and grayware should be blocked
- The inspection method should be flow-based
- A current FortiCloud account is available

Creating the profile - GUI

Do not submit files matching types

Do not submit files matching file name patterns

Use Virus Outbreak Prevention Database i ☒

Use FortiSandbox Database i ☐

Apply

1. In the following fields, enter the settings shown in the screenshot.
2. Select **Apply**.
3. Enable grayware scanning through the CLI.

```
config antivirus settings
  set grayware enable
end
```

Creating the profile - CLI

1. Enter the CLI by one of the following methods:
 - SSH through a terminal emulator
 - CLI Console access
 - FortiExplorer's CLI mode
2. Enter the following commands:

```
config antivirus profile
  edit default
    set comment "scan and delete virus"
    set inspection-mode flow-based
    set scan-botnet-connections block
    set ftgd-analytics suspicious
  config http
    set options scan
  end
  config ftp
    set options scan
  end
```

```
config imap
    set options scan
end
config pop3
    set options scan
end
config smtp
    set options scan

config nntp
    set options scan
end
config smb
    set options scan
end
end
```

3. Enable grayware scanning

```
config antivirus settings
    set grayware enable
end
```

Setting up a basic proxy-based AntiVirus profile for email traffic

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable antivirus protection on a FortiGate unit located in a satellite office.

Context:

- The satellite office does not have an internal email server. To send and retrieve email, the employees connect to an external mail server.
- There is a specific firewall security profile that handles the email traffic from the Internet to the mail server. The only traffic on this policy will be POP3 and IMAP and SMTP
- The company policy is to block viruses and connections to botnets.
- The FortiGate unit is a small model and the Internet bandwidth is limited so the policy is to not submit files to the FortiSandbox.

Creating the profile - GUI

Edit AntiVirus Profile

Treat Windows Executables in Email Attachments as Viruses
Send Files to FortiSandbox Appliance for Inspection
None All Supported Files
Do not submit files matching types
Do not submit files matching file name patterns
Use Virus Outbreak Prevention Database
Use FortiSandbox Database

Apply

1. In the following fields, enter the settings shown below:

Name	email-av
Comments	Scans email traffic from Internet for malware
Detect Viruses	Block
Inspected Protocols	all checked (HTTP, SMTP, POP3, IMAP, MAPI, and FTP).
Content Disarm and Reconstruction	checked (optional) - used to remove exploitable content and replace it with content that is known to be safe. For more information, see Content Disarm and Reconstruction (CDR)

Original File Destination	Destination to which files will be sent for inspection: FortiSandbox, File Quarantine, or Discard.
Treat Windows Executables in Email Attachments as Viruses	checked - also optionally decide whether or not to submit files matching particular types and/or file name patterns.
Send Files to FortiSandbox Appliance for Inspection	checked (All Supported Files).
Use Virus Outbreak Prevention Database	checked - used to preempt outbreaks before AV Signatures are created.
Use FortiSandbox Database	checked - supplements the AV Signature database.

2. Select **Apply**.

Creating the profile - CLI

1. Enter the CLI by one of the following methods:
 - SSH through a terminal emulator
 - CLI Console widget
 - FortiExplorer's CLI mode

2. Enter the following commands:

```
config antivirus profile
  edit "email-av"
    set comment "Scans email traffic from Internet for malware"
    set inspection-mode proxy
    config content-disarm
      set original-file-destination {fortisandbox | quarantine | discard}
      set ...
    config <protocol>
      set options scan
    end
  end
end
```

3. Additionally, if you wish to only send those files to FortiSandbox that heuristics determines as suspicious, enter the following (only available via the CLI):

```
config antivirus profile
  edit "email-av"
    set ftgd-analytics suspicious
  end
```

For more information on how to strip content from various content types from documents (hyperlinks, linked objects, embedded objects, JavaScript code), see [Content Disarm and Reconstruction \(CDR\)](#) and the [FortiOS 6.0 CLI Reference](#).

Adding the profile to a policy

In this scenario the following assumptions will be made:

- The policy that the profile is going to be added to is an IPv4 policy.
- The ID number of the policy is 11.

- The AntiVirus profile being added will be the "default" profile
- The SSL/SSH Inspection profile used will be the "default" profile

FortiClient enforcement has been moved from the Policy page to **Network > Interfaces** to enforce FortiClient registration on a desired LAN interface rather than a policy.

Adding the profile - GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Use your preferred method of finding a policy.
 - If the ID column is available you can use that.
 - You can also choose based on your knowledge of the parameters of the policy
 - Select the policy with ID value of 11
3. In the Edit Policy window, go to the Security Profiles section
4. Turn ON AntiVirus, and in the drop down menu for the field, select default
5. If the AntiVirus profile is proxy-based the Proxy Options field and drop down menu will be revealed.
6. The SSL/SSH Inspection field will automatically be set to ON and one of the profiles will need to be selected from the drop down menu. In this case default is selected.
7. The log options will depend on your requirements and resources but to verify that everything is working properly, it is a good idea to turn ON logging of All Sessions after setting up a new profile and after giving some time for logs to accumulate
8. Turn on Antivirus.
9. Select an antivirus profile.
10. Select **OK** to save the security policy.

Adding the profile - CLI

To select the antivirus profile in a security policy — CLI

```
config firewall policy
  edit 11
    set utm-status enable
    set profile-protocol-options default
    set av-profile basic_antivirus
  end
```

Block files larger than 8 MB

Set proxy options profile to block files larger than 8 MB

1. Go to **Security Profiles > Proxy Options**.
2. Edit the default or select Create New to add a new one.
3. Scroll down to the common Options Section and place a check in the box next to BlockOversized File/Email
4. The sub line Threshold (MB) will appear with a value field. Enter 8.
5. Select **OK** or **Apply**.

The proxy options profile is configured, but to block files, you must select it in the firewall policies handling the traffic that contains the files you want blocked.

To select the Proxy Options profile in a security policy

1. Go to **Policy & Objects > IPv4 Policy** (or **IPv6 Policy**, depending).
2. Edit or create a security policy.
3. Select a proxy-based security profile. You will know that there is a proxy component to the Security Profile because when a Security Profile is Proxy based the Proxy Options field will be visible (for example, select an Antivirus profile that includes proxy scanning).
4. Beside Proxy Options select the name of the MTU proxy options protocol.
5. Select **OK** to save the security policy.
6. Once you complete these steps, any files in the traffic subject to Security Profile scanning handled by this policy that are larger than 8MB will be blocked. If you have multiple firewall policies, examine each to determine if you want to apply similar file blocking the them as well.

Web filter

This section describes FortiGate web filtering for HTTP traffic. The three main parts of the web filtering function, the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service interact with each other to provide maximum control over what users on your network can view as well as protection to your network from many Internet content threats. Web Content Filter blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic.

This Handbook chapter includes [Inside FortiOS: Web Filtering](#) and provides readers an overview of the features and benefits of key FortiOS components.

For further detail than the Inside FortiOS document, we provide the following topics:

Web filter concepts

Web filtering is a means of controlling the content that an Internet user is able to view. With the popularity of web applications, the need to monitor and control web access is becoming a key component of secure content management systems that employ antivirus, web filtering, and messaging security. Important reasons for controlling web content include:

- lost productivity because employees are accessing the web for non-business reasons
- network congestion — when valuable bandwidth is used for non-business purposes, legitimate business applications suffer
- loss or exposure of confidential information through chat sites, non-approved email systems, instant messaging, and peer-to-peer file sharing
- increased exposure to web-based threats as employees surf non-business-related web sites
- legal liability when employees access/download inappropriate and offensive material
- copyright infringement caused by employees downloading and/or distributing copyrighted material.

As the number and severity of threats increase on the World Wide Web, the risk potential increases within a company's network as well. Casual non-business related web surfing has caused many businesses countless hours of legal litigation as hostile environments have been created by employees who download and view offensive content. Web-based attacks and threats are also becoming increasingly sophisticated. Threats and web-based applications that cause additional problems for corporations include:

- spyware/grayware
- phishing
- pharming
- instant messaging
- peer-to-peer file sharing
- streaming media
- blended network attacks.

Spyware, also known as grayware, is a type of computer program that attaches itself to a user's operating system. It does this without the user's consent or knowledge. It usually ends up on a computer because of

something the user does such as clicking on a button in a pop-up window. Spyware can track the user's Internet usage, cause unwanted pop-up windows, and even direct the user to a host web site. For further information, visit the FortiGuard Center.

Some of the most common types of grayware infection occur when:

- downloading shareware, freeware, or other forms of file-sharing services
- clicking on pop-up advertising
- visiting legitimate web sites infected with grayware.

Phishing is the term used to describe attacks that use web technology to trick users into revealing personal or financial information. Phishing attacks use web sites and email that claim to be from legitimate financial institutions to trick the viewer into believing that they are legitimate. Although phishing is initiated by spam email, getting the user to access the attacker's web site is always the next step.

Pharming is a next generation threat that is designed to identify and extract financial, and other key pieces of information for identity theft. Pharming is much more dangerous than phishing because it is designed to be completely hidden from the end user. Unlike phishing attacks that send out spam email requiring the user to click to a fraudulent URL, pharming attacks require no action from the user outside of their regular web surfing activities. Pharming attacks succeed by redirecting users from legitimate web sites to similar fraudulent web sites that have been created to look and feel like the authentic web site.

Instant messaging presents a number of problems. Instant messaging can be used to infect computers with spyware and viruses. Phishing attacks can be made using instant messaging. There is also a danger that employees may use instant messaging to release sensitive information to an outsider.

Peer-to-peer (P2P) networks are used for file sharing. Such files may contain viruses. Peer-to-peer applications take up valuable network resources and may lower employee productivity but also have legal implications with the downloading of copyrighted or sensitive company material.

Streaming media is a method of delivering multimedia, usually in the form of audio or video to Internet users. Viewing streaming media impacts legitimate business by using valuable bandwidth.

Blended network threats are rising and the sophistication of network threats is increasing with each new attack. Attackers learn from each successful attack and enhance and update their attack code to become more dangerous and to spread faster. Blended attacks use a combination of methods to spread and cause damage. Using virus or network worm techniques combined with known system vulnerabilities, blended threats can quickly spread through email, web sites, and Trojan applications. Examples of blended threats include Nimda, Code Red, Slammer, and Blaster. Blended attacks can be designed to perform different types of attacks, which include disrupting network services, destroying or stealing information, and installing stealthy backdoor applications to grant remote access.

Different ways of controlling access

The methods available for monitoring and controlling Internet access range from manual and educational methods to fully automated systems designed to scan, inspect, rate and control web activity.

Common web access control mechanisms include:

- establishing and implementing a well-written usage policy in the organization on proper Internet, email, and computer conduct
- installing monitoring tools that record and report on Internet usage
- implementing policy-based tools that capture, rate, and block URLs.

The following information shows how the filters interact and how to use them to your advantage.

Order of web filtering

The FortiGate unit applies web filters in a specific order:

1. URL filter
2. FortiGuard Web Filter
3. web content filter
4. web script filter
5. antivirus scanning.

If you have blocked a FortiGuard Web Filter category but want certain users to have access to URLs within that pattern, you can use the **Override** within the FortiGuard Web Filter. This will allow you to specify which users have access to which blocked URLs and how long they have that access. For example, if you want a user to be able to access www.example.com for one hour, you can use the override to set up the exemption. Any user listed in an override must fill out an online authentication form that is presented when they try to access a blocked URL before the FortiGate unit will grant access to it.

If you have blocked a FortiGuard Web Filter category but want users within a specific Web Filter profile to have access to URLs within that pattern, you can use the following CLI command below to override (this will have no timeout affiliated to it):

CLI syntax:

```
config webfilter profile
  edit <profile>
    config web
      set whitelist exempt-av exempt-dlp exempt-rangeblock extended-log-others
    end
  end
```

This command will set a Web Filter profile that exempts AV, DLP, RangeBlock, and supports extended log by FortiGuard whitelist.

Inspection modes

This topic briefly discusses proxy and flow-based inspection modes. For more information on flow vs. proxy inspection modes on your FortiGate and how they impact web filtering, see [Individual Security Profile considerations](#) in the [Inspection Modes](#) section.

Proxy

Proxy-based inspection involves buffering traffic and examining it as a whole before determining an action. The process of having the whole of the data to analyze allows for the examination of more points of data than the flow-based or [DNS methods](#).

The advantage of a proxy-based method is that the inspection can be more thorough than the other methods, yielding fewer false positive or negative results in the data analysis.

Flow-based

The flow-based inspection method examines the file as it passes through the FortiGate unit without any buffering. As each packet of the traffic arrives it is processed and forwarded without waiting for the complete file or web page.

The advantage of the flow-based method is that the user sees a faster response time for HTTP requests and there is less chance of a time-out error due to the server at the other end responding slowly.

The disadvantages of this method are: (1) there is a higher probability of a false positive or negative in the analysis of the data; and, (2) a number of security features that can be used in the proxy-based method are not available in the flow-based inspection method. There are also fewer actions available based on the categorization of the website by FortiGuard services.

In flow mode, Web Filter profiles only include flow-mode features. Web filtering is still done with the same engines and to the same accuracy, but some inspection options are limited or not available in flow mode.

Configuring Web Filter profiles in flow-mode is different depending on the **NGFW mode** selected.

See ["What's new in FortiOS 6.0.1" on page 2381](#) and [Individual Security Profile Considerations](#) in the [Inspection Modes](#) section for more details on flow vs. proxy inspection modes on your FortiGate.

FortiGuard Web Filtering Service

FortiGuard Web Filtering is a managed web filtering solution available by subscription from Fortinet. Before you begin to use the FortiGuard Web Filtering options, verify that you have a valid subscription to the service for your FortiGate firewall.

FortiGuard Web Filtering enhances the web filtering features supplied with your FortiGate unit by sorting billions of web pages into a wide range of categories users can allow or block. The FortiGate unit accesses the nearest FortiGuard Web Filtering Service Point to determine the category of a requested web page, and then applies the security policy configured for that user or interface. FortiGuard Web Filtering supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).

FortiGuard Web Filtering includes over 45 million individual ratings of web sites that apply to more than two billion pages. Pages are sorted and rated into several dozen categories administrators can allow or block. Categories may be added or updated as the Internet evolves. To make configuration simpler, you can also choose to allow or block entire groups of categories. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

FortiGuard Web Filtering ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. Users can notify the FortiGuard Web Filtering Service Points if they feel a web page is not categorized correctly, so that the service can update the categories in a timely fashion.

FortiGuard web filtering and your FortiGate unit

When FortiGuard Web Filtering is enabled in a web filter or a DNS filter profile, the setting is applied to all firewall policies that use this profile. When a request for a web page appears in traffic controlled by one of these firewall policies, the URL is sent to the nearest FortiGuard server. The URL category is returned. If the category is blocked, the FortiGate unit provides a replacement message in place of the requested page. If the category is not blocked, the page request is sent to the requested URL as normal.

FortiGuard web filtering actions

The possible actions are:

- **Allow** permits access to the sites within the category.
- **Block** prevents access to sites within the category. Users attempting to access a blocked site will receive a replacement message explaining that access to the site is blocked.
- **Monitor** permits and logs access to sites in the category. You may also enable user quotas when enabling the monitor action.
- **Warning** presents the user with a message, allowing them to continue if they choose.
- **Authenticate** requires a user to authenticate with the FortiGate unit before being allowed access to the category or category group.

The options of actions available will depend on the mode of inspection.

- Proxy - Allow, Block, Monitor, Warning, Authenticate and Disable.
- Flow-based, policy-based - Allow, Block & Monitor.
- Flow-based, profile-based - Allow, Deny

Configuring Web Filter profiles in flow-mode is different depending on the [NGFW mode](#) selected.

Web filtering flowchart

FortiGuard web filtering categories

The following tables identify each FortiGuard web filtering category (organized by group) along with associated category IDs. You can access the current list of category IDs through the CLI.

```
config webfilter profile
edit default
config ftgd-wf
config filters
edit 1
set category ?
```

For a complete description of each web filtering category, visit <http://www.fortiguards.com/webfilter/categories>.

Local categories

Users can define custom or local categories. See [Overriding FortiGuard Website Categorization](#) for details.

FortiGuard web filtering usage quotas

In addition to using category and classification blocks and overrides to limit user access to URLs, you can set a daily quota by category, category group, or classification. Quotas allow access for a specified length of time or a specific bandwidth, calculated separately for each user. Quotas are reset every day at midnight.

Users must authenticate with the FortiGate unit. The quota is applied to each user individually so the FortiGate must be able to identify each user. One way to do this is to configure a security policy using the identity-based policy feature. Apply the web filter profile in which you have configured FortiGuard Web Filter and FortiGuard Web Filter quotas to such a security policy.

The use of FortiGuard Web Filtering quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

Editing the web filter profile resets the quota timers for all users.

When a user first attempts to access a URL, they're prompted to authenticate with the FortiGate unit. When they provide their user name and password, the FortiGate unit recognizes them, determines their quota allowances, and monitors their web use. The category and classification of each page they visit is checked and FortiGate unit adjusts the user's remaining available quota for the category or classification.

Quota hierarchy

You can apply quotas to categories and category groups. Only one quota per user can be active at any one time. The one used depends on how you configure the FortiGuard Web Filter.

When a user visits a URL, the FortiGate unit queries the FortiGuard servers for the category of the URL. From highest to lowest, the relative priority of the quotas are:

1. Category
2. Category group

Configuring web filter profiles

Enabling FortiGuard web filter

FortiGuard Web Filter is enabled and configured within web filter profiles by enabling FortiGuard Categories. The service is engaged by turning on the Web Filter profile and selecting a profile that has FortiGuard Categories enabled on one or more active policies being run by the firewall.

There is also a system wide setting for the enabling or disabling of FortiGuard Web Filter that is only in the CLI.

```
config system fortiguard
    set webfilter-force-off
```

The two options on this setting are enable or disable. The syntax of the settings name is "force-off" so in order to enable FortiGuard Webfilter you have to choose disable for the setting and enable if you want to turn it off.

General configuration steps

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile, edit an existing one, or clone and edit an existing one.
3. If you are using FortiGuard Categories, enable the FortiGuard Categories, select the categories and select the action to be performed.
4. Configure any **Category Usage Quotas** needed. (Proxy Mode)
5. Allow blocked override if required. (Proxy Mode)
6. Set up **Safe Search** settings and/or YouTube Education settings. (Proxy & Flow-based)
7. Configure **Static URL Settings**. (All Modes)
8. Configure **Rating Options**. (All Modes)
9. Configure **Proxy Options**.
10. Save the filter and web filter profile.

11. To complete the configuration, you need to select the security policy controlling the network traffic you want to restrict. Then, in the security policy, enable Web Filter and select the appropriate web filter profile from the list.

Configuring FortiGuard Web Filter settings

FortiGuard Web Filter includes a number of settings that allow you to determine various aspects of the filtering behavior.

Getting to the Edit Web Filter Profile configuration window

Once you have gotten to the profile configuration window there are a number of settings that can be used, most of which are optional. We will treat each of these options separately, but present the common instructions of how to get to the profile editing page here.

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile, edit an existing one, or clone and then edit an existing one.
 - a. New profile:
 - i. Select the **Create New** icon, in the upper right of the window (looks like a plus sign in a circle) **OR**
 - ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Select the **Create New** icon in the upper left.
 - b. Edit existing profile:
 - i. Select the name of the profile that you wish to edit from the drop-down menu **OR**
 - ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Highlight the name of the profile from the list and select **Edit** from the options above the list.
 - c. Clone a profile:
 - i. Select **Clone** icon in the upper right corner of the window (looks like one square overlapping another) **OR**
 - ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Highlight the name of the profile from the list and select **Clone** from the options above the list.
3. Make sure there is a valid name, and comment if you want.
4. Configure the settings to best achieve your specific requirements
5. Select **Apply** or **OK**, depending on whether you are editing, creating, or cloning a profile.

In older versions of FortiOS there was a character limitation for the URL of 2048 bytes or approximately 321 characters. If the URL you were trying to reach was longer the URL sent to FortiGuard would be truncated and the service would be unable to categorize the site. Starting in version 5 of the firmware, the parsed URL has been increase to 4 Kilobytes, effectively doubling the length of a URL capable of being categorized.

To configure the FortiGuard Web Filter categories

1. Go to the **Edit Web Filter Profile** window.
2. The category groups are listed in a widget. You can expand each category group to view and configure every sub-category individually within the groups. If you change the setting of a category group, all categories within the group inherit the change.
3. Select the category groups and categories to which you want to apply an action.
To assign an action to a category left click on the category and select from the pop up menu.
4. Select **Apply** or **OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

If you look at your logs carefully, you may notice that not every URL connection in the log shows a category. They are left blank. If you take one of those URL and enter it in the FortiGuard website designed to show the category for a URL it will successfully categorize it.

The reason for this is that to optimize speed throughput and reduce the load on the FortiGuard servers the FortiGate does not determine a category rating on scripts and css files.

Configuring FortiGuard Category quotas

1. Go to the **Edit Web Filter Profile** window
2. Verify that the categories that need to have quotas on them are set to one of these actions:
 - **Monitor**
 - **Warning**
 - **Authenticate**
3. Under **Category Usage Quota**, Select **Create New or Edit**
4. In the **New/Edit Quota** window that pops up, enable or disable the specific categories for that quota.
5. At the bottom of the widget, select a quota type and daily allowance for each user:
 - **Time** -- can be entered in **Hours**, **Minutes**, or **Seconds**.
 - **Traffic** -- can be entered in **Bytes**, **KB**, **MB**, or **GB** The value must be greater than 0.
6. Select **Apply or OK**.
7. Continue with any other configuration in the profile
8. Select **Apply or OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

The use of FortiGuard Web Filtering quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

Editing the web filter profile resets the quota timers for all users.

Configure Allowed Blocked Overrides

1. Go to the **Edit Web Filter Profile** window.
2. Enable **Allow Blocked Override**
3. In the Apply to Group(s) field select the desired **User Group**
4. In the Assign to Profile field, select the desired profile

Configure search engine

There are 2 primary configuration settings in this section.

Enable SafeSearch

To enable the SafeSearch settings

1. Go to the **Edit Web Filter Profile** window.
2. Enable **SafeSearch**
3. Enable Search Engine SafeSearch
4. Enable YouTube Filter
 - a. Enter the YouTube User ID in the Text field

Web Filter in flow mode does not support Safe Search

Log all search keywords

In the GUI, the configuration setting is limited to a checkbox.

Configure static URL filter

Web content filter

To enable the web content filter and set the content block threshold

1. Go to the **Edit Web Filter Profile** window.
2. In the **Static URL Filter** section enable **Web Content Filter**.
3. Select **Create New**.
4. Select the **Pattern Type**.
5. Enter the content **Pattern**.
6. Enter the **Language** from the dropdown menu.
7. Select **Block** or **Exempt**, as required, from the **Action** list.
8. Select **Enable**.
9. Select **OK**.

Configure rating options

Allow Websites When a Rating error Occurs

In the GUI, the configuration setting is limited to a checkbox.

Rate URLs by Domain and IP Address

In the GUI, the configuration setting is limited to a checkbox.

Block HTTP Redirects by Rating

In the GUI, the configuration setting is limited to a checkbox.

Rate Images by URL (Blocked images will be replaced with blanks)

In the GUI, the configuration setting is limited to a checkbox.

Configure Proxy Options

Restrict Google Account Usage to Specific Domains

Configuring the feature in the GUI

Go to **Security Profiles > Web Filter**.

In the **Proxy Options** section, check the box next to **Restrict to Corporate Google Accounts Only**.

Use the **Create New** link within the widget to add the appropriate Google domains that will be allowed.

Configuring the feature in the CLI

To configure this option in the CLI, the URL filter must refer to a web-proxy profile that is using the Modifying HTTP Request Headers feature. The command is only visible when the action for the entry in the URL filter is set to either allow or monitor.

1. Configure the proxy options:

```
config web-proxy profile
  edit "googleproxy"
    config headers
      edit 1
        set name "X-GoogApps-Allowed-Domains"
        set content "fortinet.com, Ladan.ca"
      end
    end
  end
end
```

2. Set a web filter profile to use the proxy options

```
config webfilter urlfilter
  edit 1
    config entries
      edit "*.google.com"
        set type wildcard
        set action {allow | monitor}
        set web-proxy-profile <profile>
      end
    end
  end
end
```

In the CLI, you can also add, modify, and remove header fields in HTTP request when scanning web traffic in proxy-mode. If a header field exists when your FortiGate receives the request, its content will be modified based on the configurations in the URL filter.

Web Resume Download block

In the GUI, the configuration setting is limited to a checkbox.

Provide Details for Blocked HTTP 4xx and 5xx Errors

In the GUI, the configuration setting is limited to a checkbox.

HTTP POST Action

Remove Java Applet Filter

In the GUI, the configuration setting is limited to a checkbox.

Remove ActiveX Filter

In the GUI, the configuration setting is limited to a checkbox.

Remove Cookie Filter

In the GUI, the configuration setting is limited to a checkbox.

Overriding FortiGuard website categorization

In most things there is an exception to the rule. When it comes to the rules about who is allowed to go to which websites in spite of the rules or in this case, policies, it seems that there are more exceptions than to most rules. There are numerous valid reasons and scenarios for exceptions so it follows that there needs to be a way to accommodate this exception.

The different methods of override

There are two different ways to override web filtering behavior based on FortiGuard categorization of a websites if you are operating in proxy-based inspection.

The second method has two variations in implementation and each of the three has a different level of granularity.

1. Using Alternate Categories

Web Rating Overrides

This method manually assigns a specific website to a different Fortinet category or a locally created category.

2. Using Alternate Profiles

Administrative Override or Allow users to override blocked categories

In this method all of the traffic going through the FortiGate unit, using identity based policies and a Web Filtering profile has the option where configured users or IP addresses can use an alternative Web Filter profile when attempting to access blocked websites.

Using Alternate Categories

Web Rating Overrides

There are two approaches to overriding the FortiGuard Web Filtering. The first is an identity-based method that can be configured using a combination of identity-based policies and specifically designed webfilter profiles. This is addressed in the Firewall Handbook.

The second method is the system-wide approach that locally (on the FortiGate Firewall) reassigns a URL to a different FortiGuard Category or even subcategory. This is where you can assign a specific URL to the FortiGuard Category that you want to you can also set the URL to one of the Custom Categories that you have created

The Web Rating Overrides option is available because different people will have different criteria for how they categorize websites. Even if the criteria is the same an organization may have reason to block the bulk of a category but need to be able to access specific URLs that are assigned to that category.

A hypothetical example could be that a website, example.com is categorized as being in the Sub-Category Pornography. The law offices of Barrister, Solicitor, and Lawyer do not want their employees looking at pornography at work so they have used the FortiGuard Webfilter to block access to sites that have been assigned to the Category “Pornography”. However, the owners of example.com are clients of the law office and they are aware that example.com is for artists that specialize in nudes and erotic images. In this case two approaches can be taken. The first is that the Web Rating Override function can be used to assign example.com to Nudity and Risque instead of Pornography for the purposes of matching the criteria that the law office goes by or the site can be assigned to a Custom Category that is not blocked because the site belongs to one of their clients and they always want to be able to access the site.

Another hypothetical example from the other side of the coin. A private school has decided that a company that specializes in the online selling of books that could be considered inappropriate for children because of their violent subject matter, should not be accessible to anyone in the school. The categorization by Fortinet of the site example2.com is General Interest - Business with the subcategory of Shopping and Auction, which is a category that is allowed at the school. In this case they school could reassign the site to the Category Adult Material which is a blocked category.

Local or Custom Categories

User-defined categories can be created to allow users to block groups of URLs on a per-profile basis. The categories defined here appear in the global URL category list when configuring a web filter profile. Users can rate URLs based on the local categories.

Users can create user-defined categories then specify the URLs that belong to the category. This allows users to block groups of web sites on a per profile basis. The ratings are included in the global URL list with associated categories and compared in the same way the URL block list is processed.

Local categories and local rating features consume a large amount of CPU resources; use these features as little as possible.

The local assignment of a category overrides the FortiGuard server ratings and appear in reports as “Local” Categories or “Custom” Categories depending on the context.

CLI commands

In the CLI, the term is local category.

To create a local category:

```
config webfilter ftgd-local-cat
  edit local_category_1
    set id 140
  end
```

To set a rating to a Local Category:

```
config webfilter ftgd-local-rating
edit <url_str>
    set rating {[<category_int>] [group_str] . . .]
    set status {enable | disable}
end
```

GUI commands

In the GUI, **Local Categories** appears on the **Edit Web Filter** profile page and **Custom Categories** on the **Web Rating Overrides** page, if your FortiGate is in proxy-based or flow-based, profile-based inspection. If your FortiGate is operating with flow-based inspection and the policy-based NGFW mode, then you will not see the **Edit Web Filter** profile page.

Both these features will be used to create local categories and to apply actions to them.

Creating a Local or Custom Category

1. Go to **Security Profiles > Web Rating Overrides**.
2. Select **Custom Categories** in the top menu bar.
3. In the new window, click on **Create New**.
4. Enter the name of the custom category.
5. Select **OK**.

Configuring Web Rating Overrides

Using the GUI

1. Go to **Security Profiles > Web Rating Overrides**.
2. Select **Create New**
3. Type in the **URL** field the URL of the Website that you wish to recategorize. Do not use wildcard expressions when typing in the URL.
4. Select the **Lookup Rating** button to verify the current categorization assigned to the URL.
5. Change the **Category** field to one of the more applicable options from the drop down menu, for example, one of the custom categories just created.
6. Change the **Sub-Category** field to a more narrowly defined option within the main category.
7. Select **OK**.

It is usually recommended that you choose a category that you know will be addressed in existing Web Filter profiles so that you will not need to engage in further configuration.

Applying an Action to a Local or Custom Category

1. Go to **Security Profiles > Web Filter**.
2. Expand the **Local Categories** in the list of FortiGuard categories.
3. Right-click on a category from the list and set the action to **Allow**, **Block**, **Monitor**, **Warning**, **Authenticate**, or **Disable**.
4. Select **Apply**.

You cannot apply an action to a local category when operating in flow-based NGFW policy-based mode.

Web filtering local and remote category status

The `status` option allows you to enable or disable FortiGuard web filtering category overrides for local and remote categories. When disabled, `ssl-exempt`, `webfilter`, and `proxy-address` cannot use the category. The status cannot be set to `disable` if it has been referenced.

Syntax

```
config webfilter ftgd-local-cat
  edit <name>
    set status {disable | disable}
    set id 140
  next
end
```

Local Category scenarios

Scenario 1: The configuration of the domain name overrides the configuration for the subdirectory.

Depending on the URL specified or other aspects of configuration, the configuration of a local or custom category may not take effect. Consider a scenario where you have defined:

- example.com – local rating as “category 1”, action set to Block
- example.com/subdirectory – local rating as “category 2”, action set to Monitor
- example.com/subdirectory/page.html – local rating as “category 3”, action set to Warning.

If a user browses to “example.com”, access will be blocked. If a user browses to example.com/subdirectory, access will also be blocked, even though that address was configured to be part of category2. The configuration of the domain name overrides the configuration for the subdirectory.

However, if you configure a specific HTML page differently than the domain name, then that configuration will apply. In this scenario, the user will see a Warning message but will be able to pass through to the page.

Scenario 2: User-defined local ratings and SNI matches

In this scenario, local categories are defined and sites are added to those categories.

- There is no behavioral difference if the hostname is sent from ClientHello SNI or from HTTP request-url.
- The SNI will be used as hostname for https certificate-inspection or ssl-exempt.
- If a valid SNI exist, then SNI will be used as the domain name for url rating instead of CN in the server certificate.
- For the local rating, “example.com” will match “test.example.com”, but will not match “another_example.com”.

Using Alternate Profiles

Allow Blocked Overrides or Web Overrides

The Administrative Override feature for Web Filtering is found by going to **Security Profiles > Web Filter** and then enabling **Allow users to override blocked categories**.

The Concept

When a Web filter profile is overridden, it does not necessarily remove all control and restrictions that were previously imposed by the Web Filter. The idea is to replace a restrictive filter with a different one. In practice, it

makes sense that this will likely be a profile that is less restrictive the original one but there is nothing that forces this. The degree to which the alternate profile is less restrictive is open. It can be as much as letting the user access everything on the Internet or as little as allowing only one additional website. The usual practice is to have as few alternate profiles as are needed to allow approved people to access what they need during periods when an exception to the normal rules is needed but still having enough control that the organizations web usage policies are not compromised.

You are not restricted to having only one alternative profile as an option to the existing profile. The new profile depends on the credentials or IP address making the connection. For example, John connecting through the "Standard" profile could get the "Allow_Streaming_Video" profile while George would get the "Allow_Social_Networking_Sites" profile.

The other thing to take into account is the time factor on these overrides. They are not indefinite. The longest that an override can be enabled is for 1 year less a minute. Often these overrides are set up for short periods of time for specific reasons such as a project. Having the time limitation means that the System Administrator does not have to remember to go back and turn the feature off after the project is finished.

Identity or Address

In either case, these override features -- for specified users, user groups or IP addresses -- allow sites blocked by Web Filtering profiles to be overridden for a specified length of time. The drawback of this method of override is that it takes more planning and preparation than the rating override method. The advantage is that once this has been set up, this method requires very little in the way of administrative overhead to maintain.

When planning to use the alternative profile approach keep in mind the following: In Boolean terms, one of the following "AND" conditions has to be met before overriding the Web Filter is possible.

Based on the IP address:

- The Web Filter profile must be specified as allowing overrides
- AND the user's computer is one of the IP addresses specified
- AND the time is within the expiration time frame.

While the conditions are fewer for this situation, there is less control over who has the ability to bypass the filtering configured for the site. All someone has to do is get on a computer that is allowed to override the Web Filter and they have access.

Based on user group:

- The Web Filter profile must be specified as allowing overrides
- AND the policy the traffic is going through must be identity based
- AND the user's credentials matches the identity credentials specified
- AND the time is within the expiration time frame.

This method is the one most likely to be used as it gives more control in that the user has to have the correct credential and is more versatile because the user can use the feature from any computer that uses the correct policy to get out on the Internet.

Settings

When using an alternate profile approach to Web Filter overrides, the following settings are used to determine authentication and outcome. Not every setting is used in both methods but enough of them are common to describe them collectively.

Apply to Group(s)

This is found in the Allow Blocked Overrides configuration. Individual users can not be selected. You can select one or more of the User Groups that are recognized by the FortiGate unit, whether they are local to the system or from a third part authentication device such as a AD server through FSSO.

Original Profile

This is found in the Administrative Override configuration. In the Allow Blocked Overrides setting the configuration is right inside the profile so there is no need to specify which profile is the original one, but the Administrative Override setup is done separately from the profiles themselves.

Assign to Profile or New Profile

Despite the difference in the name of the field, this is the same thing in both variations of the feature. You select from the drop down menu the alternate Web Filter Profile that you wish to set up for this override.

Scope or Scope Range

When setting up the override in the "Allow Blocked Overrides" variation, you are given a drop-down menu next to the field name Scope while in the Administrative Override configuration you are asked to select a radio button next to the same options. In both cases this is just a way of selecting which form of credentials will be required to approve the overriding of the existing Web Filter profile.

When the Web Filter Block Override message page appears it will display a field named "Scope:" and depending on the selection, it will show the type of credentials used to determine whether or not the override is allowed. The available options are:

- **User**
This means that the authentication for permission to override will be based on whether or not the user is using a specific user account.
- **User Group**
This means that the authentication for permission to override will be based on whether or not the user account supplied as a credential is a member of the specified User Group.
- **IP**
This means that the authentication for permission to override will be based on the IP address of the computer that was used to authenticate. This would be used with computers that have multiple users. Example: If Paul logs on to the computer, engages the override using his credentials and then logs off, if the scope was based on the IP address of the computer, anybody logging in with any account on that computer would now be using the alternate override Web Filter profile.

When entering an IP address in the Administrative Override version, only individual IP addresses are allowed.

Differences between IP and Identity based scope

- Using the IP scope does not require the use of an Identity based policy.
- When using the Administrative Override variation and IP scope, you may not see a warning message when you change from using the original Web Filter profile to using the alternate profile. There is no requirement for credentials from the user so, if allowed, the page will just come up in the browser.
- **Ask**
This option is available only in the "Allowed Blocked Overrides" variation and when used configures the message

page to ask which scope the user wished to use. Normally, when the page appears the scope options are greyed out and not editable, but by using the ask option the option is dark and the user can choose from the choice of:

- User
- User Group
- IP Address

• Switch Duration

The Administrative Override sets a specified time frame that is always used for that override. The available options are:

• Predefined

Using this setting will mean that what ever is set as the duration will be the length of time that the override will be in effect. If the duration variable is set to 15 minutes the length of the override will always be 15 minutes. The option will be visible in the Override message page but the setting will be greyed out.

• Ask

Using this setting will give the person the option of setting the duration to the override when it is engaged. The user can set the duration in terms of Day, Hours and or Minutes.

• Duration

Duration is one of the areas where the two variations take a different approach, on two aspects of the setting. As already indicated the "Administrative Override" only uses a static time frame there is no option for the user to select on the fly how long it will last. The other way in which the two variation differ is that the "Allow Blocked Overrides" starts the clock when the user logs in with his credentials. For example, if the duration is 1 hour and John initiates an override at 2:00 p.m. on January 1, at the end of that hour he will revert back to using the original profile but he can go back and re-authenticate and start the process over again. The Administrative override variation starts the clock from when the override was configured, which is why it shows an expiration date and time when you are configuring it.

This option, which is available when the Switch Mode is set to Predefined is the time in minutes that the override will last when engaged by the user.

When setting up a constant duration in the Web Based Interface, minutes is the only option for units of time. To set a longer time frame or to use the units of hours or days you can use the CLI.

```
config webfilter profile
edit <name of webfilter profile>
config override
set ovr-dur <###d##h##m>
end
```

When configuring the duration you don't have to set a value for a unit you are not using. If you are not using days or hours you can use:

```
set ovr-dur 30m
```

instead of:

```
set ovr-dur 0d0h30m
```

However, each of the units of time variable has their own maximum level:

```
###d cannot be more than 364
##h cannot be more than 23
##m cannot be more than 59
```

So the maximum length that the override duration can be set to is 364 days, 23 hours, and 59 minutes.

Using cookies to authenticate users in a Web Filter override

Cookies can be used to authenticate users when a web filter override is used. This feature is available in CLI only.

CLI syntax:

```
config webfilter cookie-ovrd
    set redir-host <name or IP>
    set redir-port <port>
end

config webfilter profile
    edit <name>
        config override
            set ovr-cookie [allow | deny]
            set ovr-scope [user | user-group | ip | ask]
            set profile-type [list | radius]
            set ovr-dur-mode [constant | ask]
            set ovr-dur <duration>
            set ovr-user-group <name>
            set profile <name>
        end
    end
end
```

Threat Feed Connectors

This feature introduces the ability to dynamically import external block lists in the form of a text file (containing a list of either addresses or domains), which reside on an HTTP server. These dynamic block lists are called 'Threat Feeds'. You can use threat feeds to deny access to a source or destination IP address in Web Filter and DNS Filter profiles, SSL inspection exemptions, and as a Source/Destination in proxy policies. The block list is stored as an external resource, which is dynamically imported to the FortiGate at a configured interval (or refresh-rate) in order to maintain an updated list.

In each profile, the administrator can configure multiple threat feeds.

Threat Feeds can be configured under **Security Fabric > Fabric Connectors** by creating new **Threat Feeds**.

The **External Resources** edit page provides the following fields:

- **Type**
 - **FortiGuard Category** - The resource **Name** will appear as a "Remote Category" in Web Filter profiles and SSL inspection exemptions.
 - **IP Address** - The resource **Name** will appear as an "External Domain Block List" in DNS Filter profiles and as a "Source/Destination" in proxy policies.
 - **Domain Name** - The resource **Name** will appear as an "External Domain Block List" in DNS Filter profiles.
- **URI of external resource** - The link to an external resource file. The file should be a plain text file with one domain each line and supports simple wildcard.
- **Refresh Rate** - The time interval to refresh external resource (1 - 43200 minutes).
- The size of the file can be 10 MB, or 128,000 lines of text, whichever is most restrictive.

The domain resource is a text file which contains a domain name for each line and supports simple wildcard. For example:

```
mail.*.or.th
*-special.de.vu
http://www.*de.vu
610-pawn.com
aaliyah-hq-gallery.de.vu
abcgolocal.com
```

The address resource is a text file which contains an IP/IP range for each line (note that only IPv4 is supported in DNS profiles, so IPv6 addresses will be ignored). For example:

```
1.1.1.1
10.0.0.70
2.1.1.1
100.0.0.1-100.0.0.100
10.0.0.99-10.0.0.201
1.2.2.2/24
```

Syntax

```
config system external-resource
  edit <name>
    set type {category | address | domain}
    set category <value>
    set comments [comments]
    set resource <resource-url>
    set refresh-rate <minutes>
    set last-update <datetime>
  next
end
```

You can also configure one or more domain list threat feeds under `config dnsfilter profile`. See ["DNS filter" on page 2482](#) for more information.

Web Profile Overrides

This feature allows administrators to grant temporary access to sites that are otherwise blocked by a web filter profile. The temporary access can be granted to a user, user group, or source IP address. The time limit can be set in days, hours, or minutes. The default is 15 minutes.

Temporary access can also be granted to a user, user group, or source IP address by enabling **Allow users to override blocked categories** in a Web Filter security profile and applying that profile to the appropriate policy. In this scenario, the user will have to authenticate to gain access.

When Web Profile Overrides is in effect, a blocked access page or replacement message will not appear and authentication will not be required.

If your FortiGate is operating in flow-based inspection and policy-based NGFW mode, then you cannot create a web profile override.

Creating a Web Profile Override

Before creating a Web Profile Override, you will have to configure a user or user group if not granting temporary access to a Source IP. You will also have to configure the Web Filter security profile to be applied to the override.

1. Go to **Security Profiles > Web Profile Overrides**.
2. Select **Create New**.

3. Select:
 - The **Scope Range: User** and **User Group** should be previously configured under **User & Device**
 - The **Original Profile** that applied to the scope range.
 - The **New Profile** to apply for the override
 - The time when the override **Expires**; default is 15 minutes

SafeSearch

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch for the supported search sites enforces its use by rewriting the search URL to include the code to indicate the use of the SafeSearch feature. For example, on a Google search it would mean adding the string "&safe=active" to the URL in the search.

The search sites supported are:

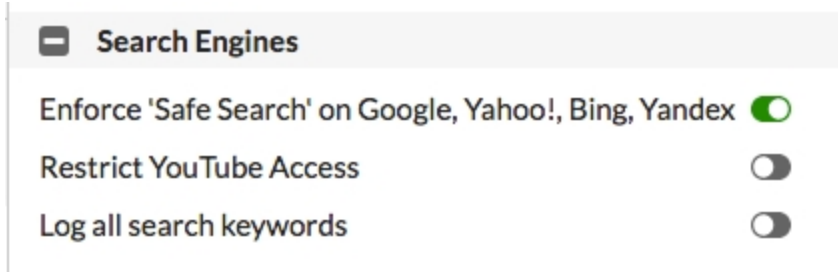

- Google
- Yahoo
- Bing
- Yandex

You can only enable SafeSearch with proxy-based inspection mode.

Enabling SafeSearch - GUI

1. Go to **Security Profiles > Web Filter** and edit or create a policy.
2. Expand **Search Engines**

Enabling SafeSearch - CLI

```
config webfilter profile
  edit default
    config web
      set safe-search <url>
    end
  end
end
```

This enforces the use of SafeSearch in traffic controlled by the firewall policies using the web filter you configure.

Search Keywords

There is also the capability to log the search keywords used in the search engines.

YouTube Education Filter

YouTube for Schools was a way to access educational videos from inside a school network. This YouTube feature gave schools the ability to access a broad set of educational videos on YouTube EDU and to select the specific videos that are accessible from within the school network.

Google decided to stop supporting YouTube for Schools (YTfS) as of July 1, 2016. Consequently, the current YouTube safe search does not work anymore.

Google provides an article entitled "[Restrict YouTube content on your network or managed devices](#)" on its support site. At this time, Google offers two options to restrict inappropriate content: DNS and HTTP header.

To restrict YouTube access, go to **Security Profiles > Web Filter**, scroll to **Search Engines** and enable **Restrict YouTube Access**. You can select either **Strict** or **Moderate** level of restriction. Your FortiGate must be in proxy mode.

YouTube Channel Filtering

This Web Filtering feature lets you block or allow matched YouTube channels using one of the following identifiers:

- **<channel-id>**
- **www.youtube.com/channel/<channel-id>**
- **www.youtube.com/user/<user-id>**
matches channel-id from <meta itemprop="channelId" content="UCGzuiiLdQZu9wxDNJHO_JnA">

- **www.youtube.com/watch?v=<string>**
matches channel-id from <meta itemprop="channelId" content="UCGzuilLdQZu9wxDNJHO_JnA">

Syntax

Note that `config youtube-channel-filter` is only available when `youtube-channel-status` is set to either `blacklist` or `whitelist`. Also note that, when defining `channel-id`, both the full URL or just the Channel ID suffix are acceptable, as shown below:

```
config webfilter profile
  edit <name>
    set youtube-channel-status {disable | blacklist | whitelist}
    config youtube-channel-filter
      edit <id>
        set channel-id <url>
      next
      edit <id>
        set channel-id <channel-id>
      next
    end
  end
end
```

Static URL filter

You can allow or block access to specific URLs by adding them to the **Static URL Filter** list. The filter allows you to block, allow, or monitor URLs by using patterns containing text, regular expressions, or wildcard characters. The FortiGate unit allows or blocks web pages matching any specified URLs or patterns and displays a replacement message instead.

URL blocking does not block access to other services that users can access with a web browser. For example, URL blocking does not block access to `ftp://ftp.example.com`. Instead, use firewall policies to deny ftp connections.

When adding a URL to the URL filter list, follow these rules:

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and file name to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls access to the news page on this web site.
- To control access to all pages with a URL that ends with `example.com`, add `example.com` to the filter list. For example, adding `example.com` controls access to `www.example.com`, `mail.example.com`, `www.finance.example.com`, and so on.
- Control access to all URLs that match patterns using text and regular expressions (or wildcard characters). For example, `example.*` matches `example.com`, `example.org`, `example.net` and so on.

URLs with an action set to exempt or monitor are not scanned for viruses. If users on the network download files through the FortiGate unit from a trusted web site, add the URL of this web site to the URL filter list with an action to pass it so the FortiGate unit does not virus scan files downloaded from this URL.

URL formats

How URL formats are detected when using HTTPS

Filter HTTPS traffic by entering a top level domain name, for example, `www.example.com` if:

- your unit does not support SSL content scanning and inspection
- you have selected the **URL filtering** option in web content profile for **HTTPS content filtering mode** under **Protocol Recognition**.

HTTPS URL filtering of encrypted sessions works by extracting the CN from the server certificate during the SSL negotiation. Since the CN only contains the domain name of the site being accessed, web filtering of encrypted HTTPS sessions can only filter by domain names.

If your unit supports SSL content scanning and inspection and if you have selected Deep Scan, you can filter HTTPS traffic in the same way as HTTP traffic.

How URL formats are detected when using HTTP

URLs with an action set to Exempt are not scanned for viruses. If users on the network download files through the unit from trusted web site, add the URL of this web site to the URL filter list with an action set to exempt so the unit does not virus scan files downloaded from this URL.

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and filename to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls the news page on this web site.
- To control access to all pages with a URL that ends with `example.com`, add `example.com` to the filter list. For example, adding `example.com` controls access to `www.example.com`, `mail.example.com`, `www.finance.example.com`, and so on.
- Control access to all URLs that match patterns created using text and regular expressions (or wildcard characters). For example, `example.*` matches `example.com`, `example.org`, `example.net` and so on.
- Fortinet URL filtering supports standard regular expressions.

If virtual domains are enabled on the unit, web filtering features are configured globally. To access these features, select **Global Configuration** on the main menu.

URL filter actions

You can select one of four actions for how traffic will be treated as it attempts to reach a site in the list.

Block

Attempts to access any URLs matching the URL pattern are denied. The user will be presented with a replacement message.

Allow

Any attempt to access a URL that matches a URL pattern with an allow action is permitted. The traffic is passed to the remaining antivirus proxy operations, including FortiGuard Web Filter, web content filter, web script filters,

and antivirus scanning.

Allow is the default action. If a URL does not appear in the URL list, it is permitted.

Monitor

Traffic to, and reply traffic from, sites matching a URL pattern with **Monitor** action applied will be allowed through in the same way as the **Allow** action. The difference with the **Monitor** action is that a log message will be generated each time a matching traffic session is established. The requests will also be subject to all other Security Profiles inspections that would normally be applied to the traffic.

Exempt

Exempt allows trusted traffic to bypass the antivirus and DLP proxy operations by default, but it functions slightly differently. In general, if you're not certain that you need to use the **Exempt** action, use **Monitor**.

Using the static URL filter to exempt scanning also prevents SSL inspection.

HTTP 1.1 connections are persistent unless declared otherwise. This means the connections will remain in place until closed or the connection times out. When a client loads a web page, the client opens a connection to the web server. If the client follows a link to another page on the same site before the connection times out, the same connection is used to request and receive the page data.

When you add a URL pattern to a URL filter list and apply the **Exempt** action, traffic sent to and replies traffic from sites matching the URL pattern will bypass all antivirus proxy operations. The connection itself inherits the exemption. This means that all subsequent reuse of the existing connection will also bypass all antivirus proxy operations. When the connection times out, the exemption is cancelled.

For example, consider a URL filter list that includes `example.com/files` configured with the **Exempt** action. A user opens a web browser and downloads a file from the URL `example.com/sample.zip`. This URL does not match the URL pattern so it is scanned for viruses. The user then downloads `example.com/files/beautiful.exe` and since this URL does match the pattern, the connection itself inherits the exempt action. The user then downloads `example.com/virus.zip`. Although this URL does not match the exempt URL pattern, a previously visited URL did, and since the connection inherited the exempt action and was re-used to download a file, the file is not scanned.

If the user next goes to an entirely different server, like `example.org/photos`, the connection to the current server cannot be reused. A new connection to `example.org` is established. This connection is not exempt. Unless the user goes back to `example.com` before the connection to that server times out, the server will close the connection. If the user returns after the connection is closed, a new connection to `example.com` is created and it is not exempt until the user visits a URL that matches the URL pattern.

Web servers typically have short time-out periods. A browser will download multiple components of a web page as quickly as possible by opening multiple connections. A web page that includes three photos will load more quickly if the browser opens four connections to the server and downloads the page and the three photos at the same time. A short time-out period on connections will close the connections faster, allowing the server to avoid unnecessarily allocating resources for a long period. The HTTP session time-out is set by the server and will vary with the server software, version, and configuration.

Using the **Exempt** action can have unintended consequences in certain circumstances. You have a web site at `example.com` and since you control the site, you trust the contents and configure `example.com` as exempt. But

example.com is hosted on a shared server with a dozen other different sites, each with a unique domain name. Because of the shared hosting, they also share the same IP address. If you visit example.com, your connection to your site becomes exempt from any antivirus proxy operations. Visits to any of the 12 other sites on the same server will reuse the same connection and the data you receive is exempt from being scanned.

Use of the **Exempt** action is not suitable for configuration in which connections through the FortiGate unit use an external proxy. For example, you use proxy.example.net for all outgoing web access. Also, as in the first example, URL filter list that includes a URL pattern of `example.com/files` configured with the **Exempt** action. Users are protected by the antivirus protection of the FortiGate unit until a user visits a URL that matches the `example.com/files` URL pattern. The pattern is configured with the **Exempt** action so the connection to the server inherits the exemption. With a proxy however, the connection is from the user to the proxy. Therefore, the user is entirely unprotected until the connection times out, no matter what site he visits.

Ensure you are aware of the network topology involving any URLs to which you apply the **Exempt** action.

Status

The Web Site Filter has the option to either enable or disable individual web sites in the list. This allows for the temporary removal of the actions against a site so that it can be later reengaged without having to rewrite the configuration.

Configuring a URL filter

Consult the [Maximum Values Table](#) on the [Fortinet Document Library](#) site for up-to-date information on the number of URL filter entries allowed for your FortiGate.

You can only set a Static URL Filter with proxy-based inspection mode and flow-based inspection mode in profile-based NGFW mode.

For this example, the URL `www.example*.com` will be used. You configure the list by adding one or more URLs to it.

To add a URL to a URL filter

1. Go to **Security Profiles > Web Filter**.
2. Create a new web filter or select a one to edit.
3. Expand **Static URL Filter**, enable **URL Filter**, and select **Create**.
4. Enter the URL, without the "http", for example: `www.example*.com`.
5. Select a **Type**: **Simple**, **Reg. Expression**, or **Wildcard**. In this example, select **Wildcard**.
6. Select the **Action** to take against matching URLs: **Exempt**, **Block**, **Allow**, or **Monitor**.
7. Confirm that **Status** is enabled.
8. Select **OK**.

'Simple' Filter type

If you select the **Simple** filter type for a URL filter, the syntax is performing an exact match. Note, however, that the domain and path are separate entities in HTTP despite the fact that a user types them as a single entity and, in the case of 'simple', the rules for each part (domain and path) are different.

The 'domain' part

For the domain part, the goal of the 'simple' format is to make it easy to block a domain and all its subdomains, such that the admin only has to type "address.xy" to block "address.xy", "www.address.xy", "talk.address.xy", etc. but *not* block "youraddress.xy" or "www.youraddress.xy" which are different domains from "address.xy".

Also, the actual domain does not include http:// or https:// so this should *not* be entered or the URL filter will try to match a domain starting with http. For this reason, when you enter http:// in the URL filter via the GUI, it is automatically removed.

A trailing '/' with the domain is not needed. The GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

The 'path' part

For the path part, an exact match takes place. For example:

www.address.xy/news

blocks anything that starts with that exact path. So this matches:

www.address.xy/newsies
www.address.xy/newsforyou
www.address.xy/news/co
etc.

Also:

www.address.xy/new

likewise blocks the same as above but includes:

/newt
/newp
etc.

which is a much broader filter, matching:

www.address.xy/newstand/co
www.address.xy/news/co
etc.

In other words, the more you specify of the path, the more strictly it will match.

Here as well a trailing '/' with the URL path is not needed, the GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

Referrer URL

A new variable has been added to the Static URL Filter: `referrer-host`. If a referrer is specified, the hostname in the referrer field of the HTTP require will be compared for any entry that contains the matching URL.

If the referrer matches, then the specified action will be performed by proxy.

Configuring in the GUI

The configuration can be done in the GUI but only if advance web filtering features have been enabled by entering the following commands in the CLI:

```
config system global
    set gui-webfilter-advanced enable
end
```

After this command is used, a new column will be created in **Security Profiles > Web Filter** to set the referrer.

Configuring in the CLI

When specifying the URL filter, it needs to be identified by its ID. The URLs are listed under each entry.

To find the ID number:

```
config webfilter urlfilter
    edit ?
```

A list of the current URL filters will be listed with their ID numbers in the left column.

The syntax in the CLI for configuring an entry is:

```
config webfilter urlfilter
    edit <ID>
        config entries
            edit 1
                set url <url>
                set referrer-host <url>
                set type {simple | regex | wildcard}
                set action {block | allow | monitor | exempt}
                set status {enable | disable}
            end
        end
    end
```

Web content filter

You can control web content by blocking access to web pages containing specific words or patterns. This helps to prevent access to pages with questionable material. You can also add words, phrases, patterns, wild cards and Perl regular expressions to match content on web pages. You can add multiple web content filter lists and then select the best web content filter list for each web filter profile.

Enabling web content filtering involves three separate parts of the FortiGate configuration.

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day.
- The web filter profile specifies what sort of web filtering is applied.
- The web content filter list contains blocked and exempt patterns.

The web content filter feature scans the content of every web page that is accepted by a security policy. The system administrator can specify banned words and phrases and attach a numerical value, or score, to the importance of those words and phrases. When the web content filter scan detects banned content, it adds the

scores of banned words and phrases in the page. If the sum is higher than a threshold set in the web filter profile, the FortiGate unit blocks the page.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a web content filter list.
2. Add patterns of words, phrases, wildcards, and regular expressions that match the content to be blocked or exempted.
3. You can add the patterns in any order to the list. You need to add at least one pattern that blocks content.
4. In a web filter profile, enable the web content filter and select a web content filter list from the options list.

To complete the configuration, you need to select a security policy or create a new one. Then, in the security policy, enable **Webfilter** and select the appropriate web filter profile from the list.

Creating a web filter content list

You can create multiple content lists and then select the best one for each web filter profile. Creating your own web content lists can be accomplished only using the CLI.

This example shows how to create a web content list called inappropriate language, with two entries, offensive and rude.

To create a web filter content list

```
config webfilter content
  edit 3
    set name "inappropriate language"
    config entries
      edit offensive
        set action block
        set lang western
        set pattern-type wildcard
        set score 15
        set status enable
      next
      edit rude
        set action block
        set lang western
        set pattern-type wildcard
        set score 5
        set status enable
      end
    end
  end
end
```

Configuring a web content filter list

Once you have created the web filter content list, you need to add web content patterns to it. There are two types of patterns: **Wildcard** and **Regular Expression**.

You use the **Wildcard** setting to block or exempt one word or text strings of up to 80 characters. You can also use the wildcard symbols, such as "*" or "?", to represent one or more characters. For example, as a wildcard

expression, `forti*.com` will match `fortinet.com` and `forticare.com`. The `"*"` represents any kind of character appearing any number of times.

You use the **Regular Expression** setting to block or exempt patterns of Perl expressions, which use some of the same symbols as wildcard expressions, but for different purposes. The `"*"` represents the character before the symbol. For example, `forti*.com` will match `fortiii.com` but not `fortinet.com` or `fortiice.com`. The symbol `"i"` represents "i" in this case, appearing any number of times. RP: Add a regex example.

The maximum number of web content patterns in a list is 5000.

How content is evaluated

Every time the web content filter detects banned content on a web page, it adds the score for that content to the sum of scores for that web page. You set this score when you create a new pattern to block the content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the sum of scores equals or exceeds the threshold score, the web page is blocked. The default score for web content filter is 10 and the default threshold is 10. This means that by default a web page is blocked by a single match. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

Banned words or phrases are evaluated according to the following rules:

- The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.
- The score for any word in a phrase without quotation marks is counted.
- The score for a phrase in quotation marks is counted only if it appears exactly as written.

The following table describes how these rules are applied to the contents of a web page. Consider the following, a web page that contains only this sentence: "The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page."

Banned pattern rules

Banned pattern	Assigned score	Score added to the sum for the entire page	Threshold score	Comment
word	20	20	20	Appears twice but only counted once. Web page is blocked.
word phrase	20	40	20	Each word appears twice but only counted once giving a total score of 40. Web page is blocked
word sentence	20	20	20	"word" appears twice, "sentence" does not appear, but since any word in a phrase without quotation marks is counted, the score for this pattern is 20. Web page is blocked.
"word sentence"	20	0	20	"This phrase does not appear exactly as written. Web page is allowed.
"word or phrase"	20	20	20	This phrase appears twice but is counted only once. Web page is blocked.

Enabling the web content filter and setting the content threshold

When you enable the web content filter, the web filter will block any web pages when the sum of scores for banned content on that page exceeds the content block threshold. The threshold will be disregarded for any exemptions within the web filter list.

Web filtering example

Web filtering is particularly important for protecting school-aged children. There are legal issues associated with improper web filtering as well as a moral responsibility to keep children from viewing inappropriate material. The key is to design a web filtering system in such a way that students and staff do not fall under the same web filter profile in the FortiGate configuration. This is important because the staff may need to access websites that are off limits to the students.

School district

The background for this scenario is a school district with more than 2,300 students and 500 faculty and staff in a preschool, three elementary schools, a middle school, a high school, and a continuing education center. Each elementary school has a computer lab and the high school has three computer labs with connections to the Internet. Such easy access to the Internet ensures that every student touches a computer every day.

With such a diverse group of Internet users, it was not possible for the school district to set different Internet access levels. This meant that faculty and staff were unable to view websites that the school district had blocked. Another issue was the students' use of proxy sites to circumvent the previous web filtering system. A proxy server acts as a go-between for users seeking to view web pages from another server. If the proxy server has not been blocked by the school district, the students can access the blocked website.

When determining what websites are appropriate for each school, the district examined a number of factors, such as community standards and different needs of each school based on the age of the students.

The district decided to configure the FortiGate web filtering options to block content of an inappropriate nature and to allow each individual school to modify the options to suit the age of the students. This way, each individual school was able to add or remove blocked sites almost immediately and have greater control over their students' Internet usage.

In this simplified example of the scenario, the district wants to block any websites with the word **example** on them, as well as the website www.example.com. The first task is to create web content filter lists for the students and the teachers.

Web Filter in flow mode does not support Safe Search. The examples below use Web Filter in proxy mode.

Create a Web Filter profile for the students

1. Go to **Security Profiles > Web Filter**.
2. Select the **Create New** icon.
3. Enter the name "Students" in the name field.
4. Enable FortiGuard Categories.
 - a. Set the following categories to **Block**:

- Potentially Liable
- Adult/Mature Content
- Security Risk

URL Content

6. Go to **Search Engines** and expand the section if necessary. Enable **Enforce 'Safe Search' on Google, Yahoo!, Bing, Yandex**
7. In the **Static URL Filter** section, enable **URL Filter**.
 - a. Select **Create New**.
 - i. In the **URL** field, enter ***example*.***
 - ii. For the **Type** field, select **Wildcard**
 - iii. For the **Action** field, select **Block**
 - iv. For the **Status** field, check **enable**
 - v. Select **OK**

Web Content Filter

8. In the **Static URL Filter** section, enable **Web Content Filter**.
 - a. In the **Web Content Filter** widget, select **Create New**.
 - i. For the **Pattern Type** field, select **Reg. Expression**
 - ii. In the **Pattern** field, enter "example"
 - iii. For the **Language** field, choose Western
 - iv. For the **Action** field, select "Block"
 - v. For the **Status** field, check Enable.
 - vi. Select **OK**
9. Enable **Rate URLs by Domain and IP Address**
10. Disable **Allow websites when a rating error occurs**.
11. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
12. Select **Apply**

Create a Web Filter for the teachers

It might be more efficient if the Teacher Web Content List included the same blocked content as the student list. From time to time a teacher might have to view a blocked page. It would then be a matter of changing the **Action** from **Block** to **Allow** as the situation required. The following filter is how it could be set up for the teachers to allow them to see the "example" content if needed while keeping the blocking inappropriate material condition.

1. Go to **Security Profiles > Web Filter**.
2. Select the **Create New** icon.
3. Enter the name "Teachers" in the name field.
4. Enable FortiGuard Categories.
 - a. Set the following categories to **Block**:
 - Potentially Liable
 - Adult/Mature Content
 - Security Risk

URL Content

6. Go to **Search Engines** and expand the section if necessary. Enable **Search Engine Safe Search on Google, Yahoo!, Bing, Yandex**.
7. In the Static URL Filter section, check **Enable URL Filter**.
 - a. Select **Create New**.
 - i. In the **URL** field, enter *example*.*
 - ii. For the **Type** field, select **Wildcard**
 - iii. For the **Action** field, select Block
 - iv. For the **Status** field, check enable
 - v. Select **OK**

Web Content Filter

8. In the Static URL Filter section, check Enable Web Content Filter.
 - a. In the Web Content Filter widget, select **Create New**.
 - b. Enter the name "Teachers" in the name field.
 - i. For the **Pattern Type** field, select **Reg. Expression**
 - ii. In the **Pattern** field, enter "example"
 - iii. For the **Language** field, choose Western
 - iv. For the **Action** field, select Exempt
 - v. For the **Status** field, check Enable.
 - vi. Select **OK**
9. Check **Rate URLs by Domain and IP Address**
10. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
11. Select **OK**

To create a security policy for the students

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy being used to manage student traffic.
3. Enable **Web Filter**.
4. Select **Students** from the web filter drop-down list.
5. Select **OK**.

To create a security policy for Teachers

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the policy being used to manage teacher traffic.
3. Enable **Web Filter**.
4. Select **Teachers** from the web filter drop-down list.
5. Select **OK**.
6. Make sure that the student policy is in the sequence before the teachers' policy.

Advanced web filter configurations

Allow websites when a rating error occurs

Enable this setting to allow access to web pages that return a rating error from the FortiGuard Web Filter service.

If your FortiGate unit cannot contact the FortiGuard service temporarily, this setting determines the type of access the FortiGate unit allows until contact is re-established. If enabled, users will have full unfiltered access to all web sites. If disabled, users will not be allowed access to any web sites.

ActiveX filter

Enable to filter ActiveX scripts from web traffic. Web sites using ActiveX may not function properly with this filter enabled.

Block HTTP redirects by rating

Enable to block HTTP redirects.

Many web sites use HTTP redirects legitimately but in some cases, redirects may be designed specifically to circumvent web filtering, as the initial web page could have a different rating than the destination web page of the redirect.

This option is not supported for HTTPS.

Block Invalid URLs

Select to block web sites when their SSL certificate CN field does not contain a valid domain name.

FortiGate units always validate the CN field, regardless of whether this option is enabled. However, if this option is not selected, the following behavior occurs:

- If the request is made directly to the web server, rather than a web server proxy, the FortiGate unit queries for FortiGuard Web Filtering category or class ratings using the IP address only, not the domain name.
- If the request is to a web server proxy, the real IP address of the web server is not known. Therefore, rating queries by either or both the IP address and the domain name is not reliable. In this case, the FortiGate unit does not perform FortiGuard Web Filtering.

Enabling the Web Filter profile to block a particular category and enabling the Application Control profile will not result in blocking the URL. This occurs because proxy and flow-based profiles cannot operate together.

To ensure replacement messages show up for blocked URLs, switch the Web Filter to flow-based inspection.

Cookie filter

Enable to filter cookies from web traffic. Web sites using cookies may not function properly with this enabled.

Provide Details for Blocked HTTP 4xx and 5xx Errors

Enable to have the FortiGate unit display its own replacement message for 400 and 500-series HTTP errors. If the server error is allowed through, malicious or objectionable sites can use these common error pages to

circumvent web filtering.

HTTP POST action

Select the action to take with HTTP POST traffic. HTTP POST is the command used by your browser when you send information, such as a form you have filled-out or a file you are uploading, to a web server.

The available actions include:

Comfort

Use client comforting to slowly send data to the web server as the FortiGate unit scans the file. Use this option to prevent a server time-out when scanning or other filtering is enabled for outgoing traffic.

The client comforting settings used are those defined in the Proxy Options profile selected in the security policy.

Block

Block the HTTP POST command. This will limit users from sending information and files to web sites.

When the post request is blocked, the FortiGate unit sends the http-post-block replacement message to the web browser attempting to use the command.

Java applet filter

Enable to filter java applets from web traffic. Web sites using java applets may not function properly with this filter enabled.

Rate Images by URL

Enable to have the FortiGate retrieve ratings for individual images in addition to web sites. Images in a blocked category are not displayed even if they are part of a site in an allowed category.

Blocked images are replaced on the originating web pages with blank place-holders. Rated image file types include GIF, JPEG, PNG, BMP, and TIFF.

Rate URLs by Domain and IP Address

Enable to have the FortiGate unit request the rating of the site by URL and IP address separately, providing additional security against attempts to bypass the FortiGuard Web Filter.

If the rating determined by the domain name and the rating determined by the IP address defer the Action that is enforce will be determined by a weighting assigned to the different categories. The higher weighted category will take precedence in determining the action. This will have the side effect that sometimes the Action will be determined by the classification based on the domain name and other times it will be determined by the classification that is based on the IP address.

FortiGuard Web Filter ratings for IP addresses are not updated as quickly as ratings for URLs. This can sometimes cause the FortiGate unit to allow access to sites that should be blocked, or to block sites that should be allowed.

An example of how this would work would be if a URL's rating based on the domain name indicated that it belonged in the category Lingerie and Swimsuit, which is allowed but the category assigned to the IP address was

Pornography which has an action of Block, because the Pornography category has a higher weight the effective action is Block.

Web resume download block

Enable to prevent the resumption of a file download where it was previously interrupted. With this filter enabled, any attempt to restart an aborted download will download the file from the beginning rather than resuming from where it left off.

This prevents the unintentional download of viruses hidden in fragmented files.

Note that some types of files, such as PDF, fragment files to increase download speed and enabling this option can cause download interruptions. Enabling this option may also break certain applications that use the Range Header in the HTTP protocol, such as YUM, a Linux update manager.

Restrict Google account usage to specific domains

This feature allow the blocking of access to some Google accounts and services while allowing access to accounts that are included in the domains specified in the exception list.

Block non-English character URLs

The FortiGate will not successfully block non-English character URLs if they are added to the URL filter. In order to block access to URLs with non-English characters, the characters must be translated into their international characters.

Browse to the non-English character URL (for example, <http://www.fortinet.com/pages/ที่'นี้'-ไม่มี'เคอร์'รูประหารให้'ใคร'ตก/338419686287505?ref=stream>).

On the FortiGate, use the URL shown in the FortiGate GUI and add it the list of blocked URLs in your URL filter (for example,

<http://www.fortinet.com/pages/%E0%B8%97%E0%B8%B5%E0%B9%88%E0%B8%99%E0%B8%B5%E0%B9%88-%E0%B9%84%E0%B8%A1%E0%B9%88%E0%B8%A1%E0%B8%B5%E0%B9%80%E0%B8%A8%E0%B8%A9%E0%B8%A3%E0%B8%B1%E0%B8%90%E0%B8%9B%E0%B8%A3%E0%B8%B0%E0%B8%AB%E0%B8%B2%E0%B8%A3%E0%B9%83%E0%B8%AB%E0%B9%89%E0%B9%83%E0%B8%84%E0%B8%A3%E0%B9%81%E0%B8%94%E0%B8%81/338419686287505?ref=stream>).

Once added, further browsing to the URL will result in a blocked page.

CLI Syntax

```
config webfilter urlfilter
edit 1
set name "block_international_character_urls"
config entries
edit 1
set url "www.fortinet.com/pages/2.710850E-3120%B8%E0%B8%B53.231533E-3170%B9%E0%B8%E0%B8%B53.231533E-3170%B9%88-3.230415E-3170%B9%E0%B80X0.000000063CD94P-102211.482197E-3230%B9%E0%B80X0.0007FBFFFFCFP-102210.000000E+000%B8%B51.828043E-3210%B9%E0%B80X0P+081.828043E-3210%B80X0P+092.710850E-3120%B80X0.0000000407ED2P-102233.236834E-3170%B8%B19.036536E-3130%B8%E0%B8%9B4.247222E-3140%B80X0P+039.036683E-3130%B8%B02.121996E-3130%B80X0.0000000000008P-1022B2.710850E-3120%B8%B21.482197E-3230%B80X0P+030.000000E+000%B9%E0%B80X0P+0B2.710850E-3120%B9%E0%B9%E0%B8%E0%B80X0.0000000408355P-102232.023693E-3200%B9%E0%B8%E0%B8%81/338419686287505?ref=stream"
```

```

        set action block
      next
    end
  next
end

config webfilter urlfilter
  edit 2
    set name "block_international_character_urls"
  next
end

config webfilter profile
  edit "block_international_character_urls"
  next
end

config firewall policy
  edit 3
    set uuid cf80d386-7bcf-51e5-6e87-db207e3f0fa8
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set logtraffic all
    set webfilter-profile "block_international_character_urls"
    set profile-protocol-options "default"
    set ssl-ssh-profile "certificate-inspection"
    set nat enable
  next
end

```

Websense web filtering through WISP

WISP is a Websense protocol that allows for URLs to be extracted by a firewall and submitted to Websense systems for rating and approval checking.

This feature provides a solution for customers who have large, existing, deployed implementations of Websense security products to replace their legacy firewalls with a FortiGate family, such that they are not forced to make a change to their web filtering infrastructure at the same time.

When WISP is enabled, the FortiGate will maintain a pool of TCP connections to the WISP server. The TCP connections will be used to forward HTTP request information and log information to the WISP server and receive policy decisions.

Configuring the WISP server

In order to use WebSense's web filtering service, a WISP server per VDOM must be defined and enabled first.

```

config web-proxy wisp
  edit {name}
    # Configure Wireless Internet service provider (WISP) servers.

```

```
set name {string}    Server name. size[35]
set comment {string}  Comment. size[255]
set outgoing-ip {ipv4 address any}    WISP outgoing IP address.
set server-ip {ipv4 address any}    WISP server IP address.
set server-port {integer}    WISP server port (1 - 65535, default = 15868). range[1-65535]
set max-connections {integer}    Maximum number of web proxy WISP connections (4 - 4096, default =
64). range[4-4096]
set timeout {integer}    Period of time before WISP requests time out (1 - 15 sec, default = 5). range
[1-15]
next
end
```

Example configuration

```
config web-proxy wisp
edit 0
set outgoing-ip 0.0.0.0
set server-ip 0.0.0.0
set server-port 15868
set max-connections 64
set timeout 5
next
end
```

After configuring the WISP server, enable WISP in the web filter profile.

```
config webfilter profile
edit "wisp_only"
set wisp enable
set wisp-servers 0
next
end
```

Now you can apply the web filter profile to a firewall policy.

If you configure more than one WISP server, the load balance option can also be configured.

```
config webfilter profile
edit "wisp_only"
set wisp-algorithm {primary-secondary | round-robin | auto-learning}
next
end
```

The options for the wisp-algorithm are:

- primary-secondary: select the first healthy server in order
- round-robin: select the next healthy server
- auto-learning select the lightest loading healthy server

DNS filter

You can configure DNS web filtering to allow, block, or monitor access to web content according to FortiGuard categories. When DNS web filtering is enabled, your FortiGate must use the FortiGuard DNS service for DNS lookups. DNS lookup requests sent to the FortiGuard DNS service return with an IP address and a domain rating that includes the FortiGuard category of the web page.

If that FortiGuard category is set to **block**, the result of the DNS lookup is not returned to the requester. If the category is set to **redirect**, then the address returned to the requester points at a FortiGuard redirect page.

You can also allow or monitor access based on FortiGuard category.

Blocking DNS requests to known botnet command & control addresses

FortiGuard maintains a database containing a list of known botnet command and control (C&C) addresses. This database is updated dynamically and stored on the FortiGate and requires a valid FortiGuard AntiVirus subscription.

When you block DNS requests to known botnet C&C addresses, using IPS, DNS lookups are checked against the botnet C&C database. All matching DNS lookups are blocked. Matching uses a reverse prefix match, so all sub-domains are also blocked.

To enable this feature, go to **Security Profiles > DNS Filter**, and enable **Block DNS requests to known botnet C&C**.

Static Domain Filter

The DNS **Static Domain Filter** allows you to block, exempt, or monitor DNS requests by using IPS to look inside DNS packets and match the domain being looked up with the domains on the static URL filter list. If there is a match the DNS request can be blocked, exempted, monitored, or allowed.

If blocked, the DNS request is blocked and so the user cannot look up the address and connect to the site.

If exempted, access to the site is allowed even if another method is used to block it.

CLI commands

- Rename `webfilter-sdns-server-ip` and `webfilter-sdns-server-port`:

```
config system fortiguard
    set sdns-server-ip x.x.x.x
    set sdns-server-port 53
end
```

- Configure DNS domain filter lists in order to decide access for specific domains:

```
config dnsfilter domain-filter
    edit {id}
        set id {integer}
        set name {string}
        set comment {string}
        config entries
            edit {id}
                set id {integer}
                set domain {string}
            next
        next
    next
end
```

```

        set type {simple | regex | wildcard}
        set action {block | allow | monitor}
        set status {enable | disable}
    next
next
end

```

- Configure DNS filter profile:

```

config dnsfilter profile
  edit "dns_profile1"
    set comment ''
    config domain-filter
      set domain-filter-table <id>
      set external-blocklist [addr1] [addr2] [addr3]
    end
    config ftgd-dns
      config filters
        edit 1
          set category 49
          set action block
          set log enable
        next
        edit 2
          set category 71
          set action monitor
          set log enable
        next
      end
    end
    set log-all-url disable
    set block-action redirect
    set redirect-portal 0.0.0.0
    set block-botnet enable
  next
end

```

- Configure DNS profile in a firewall policy:

```

config firewall policy
  edit 1
    set srcintf "any"
    set dstintf "any"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "FTP"
    set utm-status enable
    set dnsfilter-profile "dns_profile1"
    set profile-protocol-options "default"
    set nat enable
  next
end

```

- Configure DNS profile in profile group:

```

config firewall profile-group
  edit "pgrp1"

```

```
set dnsfilter-profile "dns_profile1"
set profile-protocol-options "default"
next
end
```

DNS profile supports safe search

Users can take advantage of pre-defined DNS filter rules to edit DNS profiles and provide safe search for Google, Bing, and YouTube.

To add safe search to a DNS profile - GUI

1. Go to **Security Profiles > DNS Filter**.
2. Edit the default filter or create a new one.
3. Enable **Enforce 'Safe Search' on Google, Bing, YouTube**.
4. Select **Strict** or **Moderate** level for **Restrict YouTube Access**.

To add safe search to a DNS profile - CLI

```
config dnsfilter profile
edit "default"
set safe-search enable
set youtube-restrict {strict | moderate} (only available if safe-search enabled)
next
end
```

FortiGuard botnet protection

Preventing botnets from controlling your system is achieved by detecting and blocking connection attempts to known botnets. This feature also blocks connections to known phishing sites. The FortiGuard database is continually updated with addresses of known Command and Control (C&C) sites that botnet clients attempt to connect to, as well as addresses of known phishing URLs.

To enable botnet and phishing protection in a DNS Filter profile, enable **Block DNS requests to known botnet C&C**.

The latest botnet database is available from FortiGuard. To see the version of the database and display its contents, go to **System > FortiGuard > AntiVirus** and view the lists for **Botnet IPs** and **Botnet Domains**. You can look up more details about Botnet IPs and Domains on the [FortiGuard site](#).

You can block, monitor, or allow outgoing connections to botnet sites for each FortiGate interface.

The DNS Filter security profile and the botnet protection features are available for both proxy-based and flow-based inspection modes.

Application control

Using the Application Control Security Profiles feature, your FortiGate unit can detect and take action against network traffic depending on the application generating the traffic. Based on FortiGate Intrusion Protection protocol decoders, application control is a user-friendly and powerful way to use Intrusion Protection features to log and manage the behavior of application traffic passing through the FortiGate unit. Application control uses IPS protocol decoders that can analyze network traffic to detect application traffic even if the traffic uses non-standard ports or protocols. Application control supports detection for traffic using HTTP protocol (versions 1.0, 1.1, and 2.0).

The FortiGate unit can recognize the network traffic generated by a large number of applications. You can create application control sensors that specify the action to take with the traffic of the applications you need to manage and the network on which they are active, and then add application control sensors to the firewall policies that control the network traffic you need to monitor.

Fortinet is constantly adding to the list of applications detected through maintenance of the FortiGuard Application Control Database. This database is part of the FortiGuard Intrusion Protection System Database because intrusion protection protocol decoders are used for application control and both of these databases have the same version number.

Cloud Access Security Inspection (CASI) is merged with Application Control resulting in [changes to the GUI and the CLI](#).

You can identify the version of the application control database installed on your unit by going to the **Licenses** widget on the **Dashboard** and hovering over the **IPS & Application Control** line; the status, expiry date, and version will be displayed. Additionally, you can see the complete list of applications supported by FortiGuard Application Control on the [FortiGuard](#) site or <http://fortiguard.com/appcontrol>. This web page lists all of the supported applications. You can select any application name to see details about the application.

Application Control is a standard part of any FortiCare support contract and the database for Application Control signatures is separate from the IPS database. However, botnet application signatures are still part of the IPS signature database since these are more closely related with security issues and less about application detection.

This Handbook chapter includes [Inside FortiOS: Application Control](#) and provides readers an overview of the features and benefits of key FortiOS 5.6 components. For readers needing to delve into greater detail, we provide the following topics:

Application control concepts

You can control network traffic generally by the source or destination address, or by the port, the quantity or similar attributes of the traffic itself in the security policy. If you want to control the flow of traffic from a specific application, these methods may not be sufficient to precisely define the traffic. To address this problem, the application control feature examines the traffic itself for signatures unique to the application generating it. Application control does not require knowledge of any server addresses or ports. The FortiGate unit includes signatures for over 2,000 applications, services, and protocols.

Updated and new application signatures are delivered to your FortiGate unit as part of your FortiGuard Application Control Service subscription, which is a free service. Fortinet is constantly increasing the number of applications that this feature can detect by adding applications to the FortiGuard Application Control Database. Because intrusion protection protocol decoders are used for application control, the application control database is part of the FortiGuard Intrusion Protection System Database. Both of these databases have the same version number.

You can find the version of the application control database installed on your unit by going to the **Licenses** widget on the **Dashboard** and hovering over the **IPS& Application Control** line; the status, expiry date, and version will be displayed.

To see the complete list of applications supported by FortiGuard Application Control go to the [FortiGuard](http://fortiguard.com/appcontrol) site or <http://fortiguard.com/appcontrol>. This web page lists all of the supported applications. You can select any application name to see details about the application.

Enabling application control in profile-based modes

Application control examines your network traffic for traffic generated by the applications you want it to control. The configuration steps outlined below are for FortiGate's operating in proxy-based inspection and flow-based inspection with profile-based NGFW modes. For FortiGate's operating in NGFW policy-based mode, see [Enabling application control in NGFW policy-based mode](#).

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an application sensor.
2. Configure the sensor to include the signatures for the application traffic you want the FortiGate unit to detect.
3. Enable any other applicable options.
4. Enable application control in a security policy and select the application sensor.

Creating an application sensor

You need to create an application sensor before you can enable application control.

To create an application sensor

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter the name of the new application sensor.
4. Optionally, enter descriptive **Comments**.

Adding applications to an application sensor

Once you have created an application sensor, you need to define the applications that you want to control. You can add applications and filters using categories, application overrides, and/or filter overrides. Categories will allow you to choose groups of signatures based on a category type. Application overrides allow you to choose individual applications. Filter overrides allow you to select groups of applications and override the application signature settings for them.

To add a category of signatures to the sensor.

1. Go to **Security Profiles > Application Control**.
2. Under **Categories**, you may select from the following:
 - Business
 - Cloud,.IT
 - Collaboration
 - Email
 - Game
 - General.Interest
 - Industrial
 - Mobile
 - Network.Service
 - P2P
 - Proxy
 - Remote.Access
 - Social.Media
 - Storage.Backup
 - Update
 - Video/Audio
 - VoIP
 - Web.Client
 - Unknown Applications

When selecting the category that you intend to work with, left click on the icon next to the category name to see a drop down menu that includes these actions:

- Allow
- Monitor
- Block
- Quarantine
- View Signatures

These actions are briefly defined under [Application control actions on page 2489](#).

3. If you wish to add individual applications, select **Add Signatures** under **Application Overrides**.
 - a. Use the **Add Filter** search field to narrow down the list of possible signatures by a series of attributes.
 - b. When finished, select **Use Selected Signatures**.
4. If you wish to add advanced filters, select **Add Filter** under **Filter Overrides**.
 - a. Use the Add Filter search field to narrow down the list of possible filters by a series of attributes.
 - b. When finished, select **Use Filters**.
4. Select, if applicable, from the following options:
 - **Allow and Log DNS Traffic**
 - **Replacement Messages for HTTP-based Applications**
6. Select **OK**.

Applying the application sensor to a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the application sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Click the **Edit** icon.
4. Under the heading **Security Profiles** toggle the button next to **Application Control** to enable the feature.
5. In the drop down menu field next to the **Application Control** select the application sensor you wish to apply to the policy.
6. Select **OK**.

Creating a new custom application signature

If you have to deal with an application that is not already in the **Application List** you have the option to create a new application signature.

1. Go to **Security Profiles > Application Control**.
2. Select the link in the upper right corner, **[View Application Signatures]**
3. Select the **Create New** icon
4. Give the new signature a name (no spaces) in the **Name** field.
5. Enter a brief description in the **Comments** field
6. Enter the text for the signature in the signature field. Use the rules found under [Custom IPS signature](#) to determine syntax.
7. Select **OK**.

You can configure rate based application control signatures in the CLI Console using similar IPS signature rate CLI commands.

For more information on this and the CLI syntax, see [IPS signature rate count threshold](#) on page 2505

Messages in response to blocked applications

Once an Application Control sensor has been configured to block a specified application and applied to a policy it would seem inevitable that at some point an application will end up getting blocked, even if it is only to test the functionality of the control. When this happens, the sensor can be set to either display a message to offending user or to just block without any notification. The default setting is to display a message. Setting this up is done in the CLI.

```
config application list
  edit <name of the sensor>
    set app-replacemsg {enable | disable}
  end
```

When blocking applications, there is no replacement message for SSL traffic with certificate inspection applied.

When SSL deep inspection is enabled, a replacement message will appear depending on the protocol. For example, with HTTP2, the blocking is done in the SSL key exchange once the first server packet is delivered and replacement messages can not be displayed.

P2P application detection

P2P software tends to be evasive. You may be able to enhance P2P application detection by matching patterns found in the most recent three minutes of P2P traffic to determine if new traffic is P2P. Three minutes is the length of time information about matched P2P traffic remains in shared memory.

For example, the CLI commands below will result in the Intrusion Prevention System (IPS) looking for patterns formed by Skype traffic.

```
config application list
  edit <app_list_str>
    set p2p-black-list skype
  end
end
```

Application control actions

Allow

This action allows the targeted traffic to continue on through the FortiGate unit.

Monitor

This action allows the targeted traffic to continue on through the FortiGate unit but logs the traffic for analysis.

Block

This action prevents all traffic from reaching the application and logs all occurrences.

Quarantine

This action allows you to quarantine or block access to an application for a specified duration that can be entered in days, hours, and minutes. The default is 5 minutes.

View Signatures

This option brings up a window that displays a list of the signatures with the following columns:

- Name
- Category
- Technology - Technology is broken down into 3 technology models as well as the more basic Network-Protocol which would can be used as a catch all for anything not covered by the more narrowly defined technologies of:
 - Browser-Based
 - Client-Server

- Peer-to-Peer
- Popularity - Popularity is broken down into 5 levels of popularity represented by stars.
- Risk - The Risk property does not indicate the level of risk but the type of impact that is likely to occur by allowing the traffic from that application to occur.

Traffic Shaping

Prior to the release of FortiOS 5.4.0, application control traffic shaping was configured in the **Security Profiles > Application Control** interface. There is now a specific section for traffic shaping policies in **Policy & Objects > Traffic Shaping Policy**. See [Traffic shaping methods](#) in the chapter on Traffic Shaping for details

Application considerations

Some applications behave differently from most others. You should be aware of these differences before using application control to regulate their use.

IM applications

IM applications are controlled by either permitting or denying the users from logging in to the service. Individual IM accounts are configured as to whether or not they are permitted and then there is a global policy for how to action unknown users, by the application and whether to add the user to the black list or the white list. IM applications fall under the **Collaboration** category in the application signature database.

Skype

Based on the NAT firewall type, Skype takes advantage of several NAT firewall traversal methods, such as STUN (Simple Traversal of UDP through NAT), ICE (Interactive Connectivity Establishment) and TURN (Traversal Using Relay NAT), to make the connection.

The Skype client may try to log in with either UDP or TCP, on different ports, especially well-known service ports, such as HTTP (80) and HTTPS (443), because these ports are normally allowed in firewall settings. A client who has previously logged in successfully could start with the known good approach, then fall back on another approach if the known one fails.

The Skype client could also employ Connection Relay. This means if a reachable host is already connected to the Skype network, other clients can connect through this host. This makes any connected host not only a client but also a relay server.

SPDY

SPDY (pronounced speedy, it's a trademarked name not an acronym) is a networking protocol developed to increase the speed and security of HTML traffic. It was developed primarily by Google. The Application Control engine recognizes this protocol and its required SSL/TLS component within Application Control sensors. It is counted as part of application traffic for Google and other sources that use the protocol.

Application control monitor

The application monitor enables you to gain insight into the applications generating traffic on your network. When monitor is enabled in an application sensor entry and that security profile is selected in a security policy, all the detected traffic required to populate the selected charts is logged to the SQL database on the FortiGate unit hard drive. The charts are available for display in the **Applications** section of the **FortiView** menu.

Because the application monitor relies on an SQL database, the feature is available only on FortiGate units with an internal hard drive.

Application monitor data is stored on the hard drive and restarting the system does not affect the stored monitor data.

Application control data is available in **Log & Report**, if enabled.

Application control examples

The scenarios below provide a better understanding of how to implement Application Control and give some ideas as to why it would be used.

- [Blocking instant messaging](#)
- [Allowing only software updates](#)
- [Blocking Windows XP with a custom signature](#)

Blocking instant messaging

Instant messaging use is not permitted at the Example Corporation. Application control helps enforce this policy.

The configuration steps outlined below are for FortiGate's operating in proxy-based inspection and flow-based inspection with profile-based NGFW modes. For FortiGate's operating in NGFW policy-based mode, see [Enabling application control in NGFW policy-based mode](#).

Steps in this process

1. First you will create an application sensor with a single entry that monitors the category that includes instant messaging applications. You will set the list action to **Monitor**.
2. Next you will assign the sensor to a policy.
3. Then you will identify the IM applications being used on your network and modify the application sensor to **Block** use of those messaging applications

To create the application sensor

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `no_IM` for the application sensor name.
4. If the **Collaboration** category is not already set to **Monitor**, then left-click on the icon next to that category and select **Monitor** from the dropdown menu.
5. Select **OK** to save the new sensor.

To enable application control and select the application sensor

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the security policy that allows the network users to access the Internet and choose **Edit**.
3. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.

4. In the drop down menu field next to the **Application Control** select the **no_IM** application sensor.
5. To inspect all traffic, **SSL/SSH inspection** must be set to **deep-inspection** profile.
6. Select **OK**.

To identify IM applications in use on your network

1. Go to **FortiView > Applications**.
2. Select a time period from the options in the upper-right corner of the window and examine the list of applications.
3. Identify any IM applications you wish to block.

To block IM applications in use on your network

1. Go to **Security Profiles > Application Control** and edit the **no_IM** application sensor.
2. Under **Application Overrides**, click on **Add Signatures**.
3. Filter by **Name** and select the IM applications you wish to block.
4. Click on **Use Selected Signatures**.

The selected application will appear under **Application Overrides** and the action will be set to **Block**.

5. Select **Apply**.

The IM applications identified will be blocked by the security policy that has the **no IM** application sensor applied to it. If other firewall policies handle traffic that users could use for applications in the same category, enable application control with the **no IM** application sensor for those policies as well.

Allowing only software updates

Some departments at Example Corporation do not require access to the Internet to perform their duties. Management therefore decided to block their Internet access. Software updates quickly became an issue because automatic updates will not function without Internet access and manual application of updates is time-consuming.

The solution is configuring application control to allow only automatic software updates to access the Internet.

The configuration steps outlined below are for FortiGate's operating in proxy-based inspection and flow-based inspection with profile-based NGFW modes. For FortiGate's operating in NGFW policy-based mode, see [Enabling application control in NGFW policy-based mode](#).

To create an application sensor — GUI

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `Updates_Only` as the application sensor name.
4. Using the left-click and drop down on the items in the **Category** list.
 - a. Select **Monitor** from the dropdown menu.
 - b. Select **Block** for the rest of the categories.
5. Select **OK**.

To create an application sensor — CLI

```
config application list
```

```

edit Updates_Only
  config entries
    edit 1
      set category 17
      set action pass
    end
  set other-application-action block
  set unknown-application-action block
end

```

You will notice that there are some differences in the naming convention between the GUI and the CLI. For instance the **Action** in the CLI is “pass” and the **Action** in the GUI is “**Monitor**”.

Selecting the application sensor in a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the application sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Select the **Edit** icon.
4. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.
5. In the drop down menu field next to the **Application Control** select the `Updates_only` list.
6. Select **OK**.

To select the application sensor in a security policy — CLI

```

config firewall policy
  edit 1
    set utm-status enable
    set profile-protocol-options default
    set application-list Updates_Only
  end

```

Traffic handled by the security policy you modified will be scanned for application traffic. Software updates are permitted and all other application traffic is blocked.

Blocking Windows XP with a custom signature

In this example, you will use application control to block web traffic from PCs running Windows operating systems NT 5, including Windows XP and Windows Server 2003 (includes Windows virtual machines).

When a computer's operating system lacks vendor support, it becomes a threat to the network because newly discovered exploits will not be patched. Using the FortiGate application control feature, you can restrict these computers from accessing external resources.

This example will only block web traffic from computers running the affected operating systems. If you wish to block these computers from being on the network entirely, further action will be necessary. However, the logs generated can be used to identify the computers you wish to block.

1. Go to **System > Feature Select**. Enable **Application Control** and **Apply** your changes.
2. Go to **Security Profiles > Application Control** and select **View Application Signatures**.
3. Create a new signature with the syntax below. You can copy and paste the text into the **Signature** field. Name the signature *Block-Windows-NT5*.

```
F-SBID(--attack_id 8055;--vuln_id 8055;--name
"Windows.NT.5.Web.Surfing";--flow from_client;--pattern !"FCT";--
pattern "Windows NT 5.";--no_case;--context header;--weight 40;--
service HTTP;--protocol tcp;--app_cat 25;--default_action drop_
session;)
```

If you do not include keyword / value pairs for `--attack_id` or `--vuln_ID` in the signature, the FortiGate will automatically assign values.

The signature will appear at the top of the application list and be listed in the **Web.Client** category.

4. Go to **Security Profiles > Application Control** and edit the **default** policy.
5. Under **Application Overrides**, select **Add Signatures**. The new signature should appear at the top of the list. If it does not, search for the signature's name.
6. Select the signature, then select **Use Selected Signatures**.
7. Go to **Policy & Objects > IPv4 Policy** and edit the policy that allows connections from the internal network to the Internet.
8. Under **Security Profiles**, turn on **Application Control** and use the **default** profile.

Results

When a PC running one of the affected operating systems attempts to connect to the Internet using a browser, a blocked message appears. Because Application Control uses flow-based inspection, if you apply an additional security profile to your traffic that is proxy-based, the connection will simply timeout rather than display the replacement message. However, Application Control will still function.

PCs running other operating systems, including later versions of Windows, are not affected.

Go to **FortiView > All Sessions** and select the **5 minutes** view.

Filter the results to show sessions that were blocked.

You will see that the Application Control signature, shown in the **Application Name** column, was used to block traffic from PCs running older Windows versions.

For further reading, see [Custom Application & IPS Signatures](#).

Intrusion prevention

The FortiOS Intrusion Prevention System (IPS) combines signature detection and prevention with low latency and excellent reliability. With intrusion protection, you can create multiple IPS sensors, each containing a complete configuration based on signatures. Then, you can apply any IPS sensor to any security policy.

This section describes how to configure the FortiOS Intrusion Prevention settings.

This Handbook chapter includes [Inside FortiOS: Intrusion Prevention System](#) providing readers an overview of the features and benefits of key FortiOS 5.6 components. For readers needing to delve into greater detail, we provide the following:

IPS concepts

The FortiOS Intrusion Prevention System (IPS) protects your network from outside attacks. Your FortiGate unit has two techniques to deal with these attacks: anomaly- and signature-based defense.

Anomaly-based defense

Anomaly-based defense is used when network traffic itself is used as a weapon. A host can be flooded with far more traffic than it can handle, making the host inaccessible. The most common example is the denial of service (DoS) attack, in which an attacker directs a large number of computers to attempt normal access of the target system. If enough access attempts are made, the target is overwhelmed and unable to service genuine users. The attacker does not gain access to the target system, but it is not accessible to anyone else.

The FortiGate DoS feature will block traffic above a certain threshold from the attacker and allow connections from other legitimate users. The DoS policy configuration can be found in the Firewall chapter of the Handbook.

Access control lists in DoS Policies

This feature allows you to define a list of IPs/subnets/ranges in a DoS policy, and block those IPs from sending any traffic, by way of an ACL (access control list). The ACL looks similar to a firewall policy, but only checks source IP, destination IP, destination port, and protocol. To configure in the GUI, go to **Policy & Objects > IPv4 Access Control List** and create a new policy. Enter the incoming interface, the source address, the destination address, the services impacted, and, optionally, enter a comment.

CLI Syntax

```
config firewall acl
  edit 1
    set interface "port1"
    set srcaddr "google-drive"
    set dstaddr "all"
    set service "ALL"
  next
end
```

Signature-based defense

Signature-based defense is used against known attacks or vulnerability exploits. These often involve an attacker attempting to gain access to your network. The attacker must communicate with the host in an attempt to gain access and this communication will include particular commands or sequences of commands and variables. The IPS signatures include these command sequences, allowing the FortiGate unit to detect and stop the attack.

Signatures

IPS signatures are the basis of signature-based intrusion prevention. Every attack can be reduced to a particular string of commands or a sequence of commands and variables. Signatures include this information so your FortiGate unit knows what to look for in network traffic.

Signatures also include characteristics about the attack they describe. These characteristics include the network protocol in which the attack will appear, the vulnerable operating system, and the vulnerable application.

To view the complete list of signatures, go to **Security Profiles > Intrusion Prevention**, and select **View IPS Signatures**. This will include the predefined signatures and any custom signatures that you may have created.

With the release of FortiOS 5.6, the IPS signatures list page shows which IPS package is currently deployed. Users can also change their IPS package by hovering over the information icon next to the IPS package name. Text will appear that links directly to the FortiGate's **System > FortiGuard** page from the IPS Signatures list page.

Protocol decoders

Before examining network traffic for attacks, the IPS engine uses protocol decoders to identify each protocol appearing in the traffic. Attacks are protocol-specific, so your FortiGate unit conserves resources by looking for attacks only in the protocols used to transmit them. For example, the FortiGate unit will only examine HTTP traffic for the presence of a signature describing an HTTP attack.

IPS engine

Once the protocol decoders separate the network traffic by protocol, the IPS engine examines the network traffic for the attack signatures.

IPS sensors

The IPS engine does not examine network traffic for all signatures. You must first create an IPS sensor and specify which signatures are included. Add signatures to sensors individually using signature entries, or in groups using IPS filters.

To view the IPS sensors, go to **Security Profiles > Intrusion Prevention**.

You can group signatures into IPS sensors for easy selection when applying to firewall policies. You can define signatures for specific types of traffic in separate IPS sensors, and then select those sensors in profiles designed to handle that type of traffic. For example, you can specify all of the web-server related signatures in an IPS sensor, and that sensor can then be applied to a firewall policy that controls all of the traffic to and from a web server protected by the unit.

The FortiGuard Service periodically updates the pre-defined signatures, with signatures added to counter new threats. Since the signatures included in filters are defined by specifying signature attributes, new signatures matching existing filter specifications will automatically be included in those filters. For example, if you have a

filter that includes all signatures for the Windows operating system, your filter will automatically incorporate new Windows signatures as they are added.

Each IPS sensor consists of two parts: filters and overrides. Overrides are always checked before filters.

Each filter consists of a number of signature attributes. All of the signatures with those attributes, and only those attributes, are checked against traffic when the filter is run. If multiple filters are defined in an IPS Sensor, they are checked against the traffic one at a time, from top to bottom. If a match is found, the unit takes the appropriate action and stops further checking.

A signature override can modify the behavior of a signature specified in a filter. A signature override can also add a signature not specified in the sensor's filters. Custom signatures are included in an IPS sensor using overrides.

The signatures in the overrides are first compared to network traffic. If the IPS sensor does not find any matches, it then compares the signatures in each filter to network traffic, one filter at a time, from top to bottom. If no signature matches are found, the IPS sensor allows the network traffic.

The signatures included in the filter are only those matching every attribute specified. When created, a new filter has every attribute set to **all** which causes every signature to be included in the filter. If the severity is changed to high, and the target is changed to server, the filter includes only signatures checking for high priority attacks targeted at servers.

IPS filters

IPS sensors contain one or more IPS filters. A filter is a collection of signature attributes that you specify. The signatures that have all of the attributes specified in a filter are included in the IPS filter.

For example, if your FortiGate unit protects a Linux server running the Apache web server software, you could create a new filter to protect it. By setting **OS** to **Linux**, and **Application** to **Apache**, the filter will include only the signatures that apply to both Linux and Apache. If you wanted to scan for all the Linux signatures and all the Apache signatures, you would create two filters, one for each.

To view the filters in an IPS sensor, go to **Security Profiles > Intrusion Prevention**, select the IPS sensor containing the filters you want to view, and select **Edit**.

Custom/predefined signature entries

Signature entries allow you to add an individual custom or predefined IPS signature. If you need only one signature, adding a signature entry to an IPS sensor is the easiest way. Signature entries are also the only way to include custom signatures in an IPS sensor.

Another use for signature entries is to change the settings of individual signatures that are already included in a filter within the same IPS sensor. Add a signature entry with the required settings above the filter, and the signature entry will take priority.

Policies

To use an IPS sensor, you must select it in a security policy or an interface policy. An IPS sensor that is not selected in a policy will have no effect on network traffic.

IPS is most often configured as part of a security policy. Unless stated otherwise, discussion of IPS sensor use will be in regards to firewall policies in this document.

Session timers for IPS sessions

A session time-to-live (TTL) timer for IPS sessions is available to reduce synchronization problems between the FortiOS Kernel and IPS, and to reduce IPS memory usage. The timeout values can be customized.

Enabling IPS scanning

Enabling IPS scanning involves two separate features of FortiOS 5.6:

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day. Firewall policies can also be used to deny traffic, but those policies do not apply to IPS scanning.
- The IPS sensor contains filters, signature entries, or both. These specify which signatures are included in the IPS sensor.

When IPS is enabled and an IPS sensor is selected in a security policy, and all network traffic matching the policy will be checked for the signatures in the IPS sensor.

General configuration steps

For best results in configuring IPS scanning, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an IPS sensor.
2. Add signatures and /or filters.
These can be:
 - Pattern based
 - Rate based
 - Customized
3. Select a security policy or create a new one.
4. In the security policy, turn on **IPS**, and choose the IPS sensor from the list.

All the network traffic controlled by this security policy will be processed according to the settings in the policy. These settings include the IPS sensor you specify in the policy.

Creating an IPS sensor

You need to create an IPS sensor before specific signatures or filters can be chosen. The signatures can be added to a new sensor before it is saved. However, it is good practice to keep in mind that the sensor and its included filters are separate things, and that they are created separately.

To create a new IPS sensor

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the **Create New** icon in the top of the Edit IPS Sensor window.
3. Enter the name of the new IPS sensor.
4. Optionally, enter a comment. The comment will appear in the IPS sensor list.
5. Select **OK**.

A newly created sensor is empty and contains no filters or signatures. You need to add one or more filters or signatures before the sensor will be of any use.

Adding an IPS filter to a sensor

While individual signatures can be added to a sensor, a filter allows you to add multiple signatures to a sensor by specifying the characteristics of the signatures to be added.

To create a new pattern based signature and filter

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the IPS sensor to which you want to add the filter using the drop-down list in the top row of the Edit IPS Sensor window or by going to the list window.
3. Under **IPS Filters**, select **Add Filter**.
4. Configure the filter that you require. Signatures matching all of the characteristics you specify in the filter will be included in the filter. Once finished, select **Use Filters**.

Application refers to the application affected by the attack and filter options include over 25 applications.

OS refers to the Operating System affected by the attack. The options include **BSD**, **Linux**, **MacOS**, **Other**, **Solaris**, and **Windows**.

Protocol refers to the protocol that is the vector for the attack; filter options include over 35 protocols, including "other."

Severity refers to the level of threat posed by the attack. The options include **Critical**, **High**, **Medium**, **Low**, and **Info**.

Target refers to the type of device targeted by the attack. The options include **client** and **server**.

5. Once you have selected the filters you wish to add, right-click the filters and choose an action for when a signature is triggered:

Action	Description
Pass	Select Pass to allow traffic to continue to its destination. Note: to see what the default for a signature is, go to the IPS Signatures page and enable the column Action , then find the row with the signature name in it.
Monitor	Select Monitor to allow traffic to continue to its destination and log the activity. The log will appear under Log & Report but will only be visible in the GUI in the event of an intrusion.
Block	Select Block to drop traffic matching any the signatures included in the filter.
Reset	Select Reset to reset the session whenever the signature is triggered. In the CLI this action is referred to as Reject.
Default	Select Default to use the default action of the signature.
Quarantine	The quarantine based on the attacker's IP Address - Traffic from the Attacker's IP address is refused until the expiration time from the trigger is reached. You may set the Quarantine Duration to any number of Days , Hours , or Minutes .

Action	Description
Packet Logging	<p>Select to enable packet logging for the filter.</p> <p>When you enable packet logging on a filter, the unit saves a copy of the packets that match any signatures included in the filter. The packets can be analyzed later.</p> <p>For more information about packet filtering, see "Configuring packet logging options".</p>

6. Select **Apply**.

The filter is created and added to the filter list.

Adding rate based signatures

These are a subset of the signatures that are found in the database that are normally set to monitor. This group of signatures is for vulnerabilities that are normally only considered a serious threat when the targeted connections come in multiples, a little like DoS attacks.

Adding a rate based signature is straight forward. Select the enable button in the Rate Based Signature table that corresponds with the desired signature.

Customized signatures

Customized signatures must be created before they can be added to the sensor. To get more details on customized signatures check the [Custom Application & IPS Signatures](#) chapter.

Updating predefined IPS signatures

The FortiGuard Service periodically updates the predefined signatures and adds new signatures to counter emerging threats as they appear.

To ensure that your system is providing the most protection available, these updates can be scheduled as often as on an hourly basis. To configure this feature, go to **System > FortiGuard**. Under **AntiVirus & IPS Updates**, enable **Scheduled Updates**. From here you can set the updates to occur on a consistent weekly, daily, or even hourly basis.

Because the signatures included in filters are defined by specifying signature attributes, new signatures matching existing filter specifications will automatically be included in those filters. For example, if you have a filter that includes all signatures for the Windows operating system, your filter will automatically incorporate new Windows signatures as they are added.

Viewing and searching predefined IPS signatures

Go to **Security Profiles > Intrusion Prevention**. Select **[View IPS Signatures]** to view the list of existing IPS signatures. You may find signatures by paging manually through the list, apply filters, or by using the search field.

Searching manually

Signatures are displayed in a paged list, with 50 signatures per page. The bottom of the screen shows the current page and the total number of pages. You can enter a page number and press enter, to skip directly to that page. Previous Page and Next Page buttons move you through the list, one page at a time. The First Page and Last Page button take you to the beginning or end of the list.

Searching CVE-IDs

A **CVE-ID** column displaying CVE-IDs can be optionally added to the IPS Signatures list, however the column is only available if the IPS package contains CVE-IDs for signatures. CVE-IDs can be numerically filtered by selecting the CVE-ID column's arrows.

Applying filters

You can enter criteria for one or more columns, and only the signatures matching all the conditions you specify will be listed.

To apply filters

1. Go to **Security Profiles > Intrusion Prevention**. Select **[View IPS Signatures]**.
2. Select column by which to filter.
3. Select the funnel/filter icon and enter the value or values to filter by.
4. Use additional columns as needed to refine search.

The available options vary by column. For example, **Enable** allows you to choose between two options, while OS has multiple options, and you may select multiple items together. Filtering by name allows you to enter a text string and all signature names containing the string will be displayed.

IPS processing in an HA cluster

IPS processing in an HA cluster is no different than with a single FortiGate unit, from the point of view of the network user. The difference appears when a secondary unit takes over from the primary, and what happens depends on the HA mode.

Active-passive

In an active-passive HA cluster, the primary unit processes all traffic just as it would in a stand-alone configuration. Should the primary unit fail, a secondary unit will assume the role of the primary unit and begin to process network traffic. By default, the state of active communication sessions are not shared with secondary units and will not survive the fail-over condition. Once the sessions are reestablished however, traffic processing will continue as normal.

If your network requires that active sessions are taken over by the new primary unit, select **Enable Session Pick-up** in your HA configuration. Because session information must be sent to all subordinate units on a regular basis, session pick-up is a resource-intensive feature and is not enabled by default.

Active-active

The fail-over process in an active-active cluster is similar to an active-passive cluster. When the primary unit fails, a secondary unit takes over and traffic processing continues. The load-balancing schedule used to distribute sessions to the cluster members is used by the new primary unit to redistribute sessions among the remaining subordinate units. If session pick-up is not enabled, the sessions active on the failed primary are lost, and the sessions redistributed among the secondary units may also be lost. If session pick-up is enabled, all sessions are handled according to their last-known state.

Configure IPS options

The following IPS configuration options are available:

- Malicious URL database for drive-by exploits detection
- Customizable replacement message when IPS blocks traffic
- Hardware acceleration
- Extended IPS database
- Configuring the IPS engine algorithm
- Configuring the IPS engine-count
- Configuring fail-open
- Configuring the session count accuracy
- Configuring IPS intelligence
- Configuring the IPS buffer size
- Configuring protocol decoders
- Configuring security processing modules
- IPS signature rate count threshold
- Geographic location filter

Malicious URL database for drive-by exploits detection

This feature uses a local malicious URL database on the FortiGate to assist in drive-by exploits detection. The database contains all malicious URLs active in the last one month, and all drive-by exploit URLs active in the last three months. The number of URLs controlled are in the one million range.

```
config ips sensor
  edit <profile>
    set block-malicious-url [enable | disable]
  next
end
```

Customizable replacement message when IPS blocks traffic

You can edit a replacement message that will appear specifically for IPS sensor blocked Internet access. Go to **System > Replacement Messages**, select **Extended View** and find **IPS Sensor Block Page** under the **Security** heading.

Hardware acceleration for flow-based security profiles (NTurbo and IPSA)

Some FortiGate models support a feature call NTurbo that can offload flow-based firewall sessions to NP4 or NP6 network processors. Some FortiGate models also support offloading enhanced pattern matching for flow-based security profiles to CP8 or CP9 content processors. You can use the following command to configure NTurbo and IPSA:

```
config ips global
  set np-accel-mode {none | basic}
  set cp-accel-mode {none | basic | advanced}
end
```

If the `np-accel-mode` option is available, your FortiGate supports NTurbo: `none` disables NTurbo and `basic` (the default) enables NTurbo. If the `cp-accel-mode` option is available your FortiGate supports IPSA: `none` disables IPSA, `basic` enables basic IPSA and `advanced` enables enhanced IPSA which can offload more types of pattern matching than basic IPSA. `advanced` is only available on FortiGate models with two or more CP8 processors or one or more CP9 processors.

See the **Hardware Acceleration** handbook chapter for more information about NTurbo and IPSA.

Extended IPS database

Some models have access to an extended IPS Database. The extended database may affect the performance of the FortiGate unit so depending on the model of the FortiGate unit the extended database package may not be enabled by default. For example, the D-series Desktop model have this option disabled by default.

This feature can only be enabled through the CLI.

```
config ips global
    set database extended
end
```

Configuring the IPS engine algorithm

The IPS engine is able to search for signature matches in two ways. One method is faster but uses more memory, the other uses less memory but is slower. Use the `algorithm` CLI command to select one method:

```
config ips global
    set algorithm {super | high | low | engine-pick}
end
```

Specify `high` to use the faster more memory intensive method or `low` for the slower memory efficient method. The setting `super` improves the performance for FortiGate units with more than 4GB of memory. The default setting is `engine-pick`, which allows the IPS engine to choose the best method on the fly.

Configuring the IPS engine-count

FortiGate units with multiple processors can run more than one IPS engine concurrently. The `engine-count` CLI command allows you to specify how many IPS engines are used at the same time:

```
config ips global
    set engine-count <int>
end
```

The recommended and default setting is 0, which allows the FortiGate unit to determine the optimum number of IPS engines.

Configuring fail-open

IPS is likely more important to your network than uninterrupted flow of network traffic, so the fail-open behaviour of the IPS engine is disabled by default. If you would like to enable the fail-open option, use the following syntax. When enabled, if the IPS engine fails for any reason, it will fail open. This applies for inspection of all the protocols inspected by FortiOS IPS protocol decoders, including but not limited to HTTP, HTTPS, FTP, SMTP, POP3, IMAP, etc. This means that traffic continues to flow without IPS scanning. To enable:

```
config ips global
    set fail-open {enable | disable}
end
```

The default setting is `disable`.

Configuring the session count accuracy

The IPS engine can keep track of the number of open session in two ways. An accurate count uses more resources than a less accurate heuristic count.

```
config ips global
    set session-limit-mode {accurate | heuristic}
```

```
end
```

The default is `heuristic`.

Configuring IPS intelligence

Starting with FortiOS 5.2, `intelligent-mode` is a new adaptive detection method. This command is enabled the default and it means that the IPS engine will perform adaptive scanning so that, for some traffic, the FortiGate can quickly finish scanning and offload the traffic to NPU or kernel. It is a balanced method which could cover all known exploits. When disabled, the IPS engine scans every single byte.

```
config ips global
    set intelligent-mode {enable|disable}
end
```

Configuring the IPS buffer size

Set the size of the IPS buffer.

```
config ips global
    set socket-size <int>
end
```

The acceptable range is from 1 to 64 megabytes. The default size varies by model. In short, `socket-size` determines how much data the kernel passes to the IPS engine each time the engine samples packets.

Configuring protocol decoders

The FortiGate Intrusion Prevention system uses protocol decoders to identify the abnormal traffic patterns that do not meet the protocol requirements and standards. For example, the HTTP decoder monitors traffic to identify any HTTP packets that do not meet the HTTP protocol standards.

To change the ports a decoder examines, you must use the CLI. In this example, the ports examined by the DNS decoder are changed from the default 53 to 100, 200, and 300.

```
config ips decoder dns_decoder
    set port_list "100,200,300"
end
```

You cannot assign specific ports to decoders that are set to **auto** by default. These decoders can detect their traffic on any port. Specifying individual ports is not necessary.

Configuring security processing modules

FortiGate Security Processing Modules, such as the CE4, XE2, and FE8, can increase overall system performance by accelerating some security and networking processing on the interfaces they provide. They also allow the FortiGate unit to offload the processing to the security module, thereby freeing up its own processor for other tasks. The security module performs its own IPS and firewall processing, but you can configure it to favor IPS in hostile high-traffic environments.

If you have a security processing module, use the following CLI commands to configure it to devote more resources to IPS than firewall. This example shows the CLI commands required to configure a security module in slot 1 for increased IPS performance.

```
config system amc-slot
    edit sw1
        set optimization-mode fw-ips
    end
end
```

```

set ips-weight balanced
set ips-p2p disable
set ips-fail-open enable
set fp-disable none
set ipsec-inb-optimization enable
set syn-proxy-client-timer 3
set syn-proxy-server-timer 3
end

```

In addition to offloading IPS processing, security processing modules provide a hardware accelerated SYN proxy to defend against SYN flood denial of service attacks. When using a security module, configure your DoS anomaly check for `tcp_syn_flood` with the **Proxy** action. The **Proxy** action activates the hardware accelerated SYN proxy.

IPS signature rate count threshold

The IPS signature threshold can allow configuring a signature so that it will not be triggered until a rate count threshold is met. This provides a more controlled recording of attack activity. For example, if multiple login attempts produce a failed result over a short period of time then an alert would be sent and perhaps traffic blocked. This would be a more rational response than sending an alert every time a login failed.

The syntax for this configuration is as follows:

```

config ips sensor
  edit default
    config entries
      edit <Filter ID number>
        set rule <*id>
        set rate-count <integer between 1 - 65535>
        set rate-duration <integer between 1 - 65535>

```

The value of the `rate-duration` is an integer for the time in seconds.

```
set rate-mode <continuous | periodical>
```

The `rate-mode` refers to how the count threshold is met.

If the setting is “continuous”, and the action is set to block, as soon as the `rate-count` is reached the action is engaged. For example, if the count is 10, as soon as the signature is triggered 10 times the traffic would be blocked.

If the setting is “periodical”, the FortiGate allows up to the value of the `rate-count` incidents where the signature is triggered during the `rate-duration`. For example, if the rate count is 100 and the duration is 60, the signature would need to be triggered 100 times in 60 seconds for the action to be engaged.

```
set rate-track <dest-ip | dhcp-client-mac | dns-domain | none | src-ip>
```

This setting allows the tracking of one of the protocol fields within the packet.

Geographic location filter

Place filters based on geographical location. Note that routes will not be installed if the resolved IPv6 address belongs to the country in the filter.

Any country entered for `geo-filter` will prevent all destination addresses that belong to that country from being installed into static routing table:

```
config webfilter {ips-urlfilter-setting | ips-urlfilter-setting6}
```

```
edit <address>
    set geo-filter <country-name>
next
end
```

Use the following diagnose command to list the IPv4 and/or IPv6 IP ranges of a specific country:

```
diagnose geoip {iprange6 | iprange} <country-name>
```

Enabling IPS packet logging

Packet logging saves the network packets containing the traffic matching an IPS signature to the attack log. The FortiGate unit will save the logged packets to wherever the logs are configured to be stored, whether memory, internal hard drive, a FortiAnalyzer unit, or the FortiGuard Analysis and Management Service.

You can enable packet logging in the filters. Use caution in enabling packet logging in a filter. Filters configured with few restrictions can contain thousands of signatures, potentially resulting in a flood of saved packets. This would take up a great deal of space, require time to sort through, and consume considerable system resources to process. Packet logging is designed as a focused diagnostic tool and is best used with a narrow scope.

Although logging to multiple FortiAnalyzer units is supported, packet logs are not sent to the secondary and tertiary FortiAnalyzer units. Only the primary unit receives packet logs.

To enable packet logging for a filter

1. Create a filter in an IPS sensor.
2. After creating the filter, right-click the filter, and select **Enable** in the **Packet Logging** column of the filter table.
3. Select the IPS sensor in the security policy that allows the network traffic the FortiGate unit will examine for the signature.

For information on viewing and saving logged packets, see [Configuring packet logging options](#) below.

IPS logging changes

IPS operations severely affected by disk logging are moved out of the quick scanning path, including logging, SNMP trap generation, quarantine, etc.

Scanning processes are dedicated to nothing but scanning, which results in more evenly distributed CPU usage. Slow (IPS) operations are taken care of in a dedicated process, which usually stays idle.

Setting `packet-log-history` to a value larger than 1 can affect the performance of the FortiGate unit because network traffic must be buffered. The performance penalty depends on the model, the setting, and the traffic load.

Other IPS examples

Configuring basic Intrusion Prevention

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable IPS on a FortiGate unit located in a satellite office. The satellite office

contains only Windows clients.

Creating an IPS sensor

Most IPS settings are configured in an IPS sensor. IPS sensors are selected in firewall policies. This way, you can create multiple IPS sensors, and tailor them to the traffic controlled by the security policy in which they are selected. In this example, you will create one IPS sensor.

To create an IPS sensor— GUI

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the **Create New** icon in the top of the Edit IPS Sensor window.
3. In the **Name** field, enter `basic_ips`.
4. In the **Comments** field, enter `IPS for Windows clients`.
5. Select **OK**.
6. Select the **Create New** drop-down to add a new component to the sensor and for the **Sensor Type** choose **Filter Based**.
7. In the Filter Options choose the following:
 - a. For **Severity**: select all of the options
 - b. For **Target**: select **Client** only.
 - c. For **OS**: select **Windows** only.
8. For the **Action** leave as the default.
9. Select **OK** to save the filter.
10. Select **OK** to save the IPS sensor.

To create an IPS sensor — CLI

```
config ips sensor
  edit basic_ips
    set comment "IPS for Windows clients"
    config entries
      edit 1
        set location client
        set os windows
      end
    end
  end
end
```

Selecting the IPS sensor in a security policy

An IPS sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an IPS sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the IPS sensor in a security policy — GUI

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select a policy.
3. Select the **Edit** icon.
4. Enable the **IPS** option under **Security Profiles**.

5. Select the preferred IPS sensor from the dropdown menu.
6. Select **OK** to save the security policy.

To select the IPS sensor in a security policy — CLI

```
config firewall policy
  edit 1
    set utm-status enable
    set ips-sensor basic_ips
  end
```

The IPS sensor in this example is `basic_ips`. All traffic handled by the security policy you modified will be scanned for attacks against Windows clients. A small office may have only one security policy configured. If you have multiple policies, consider enabling IPS scanning for all of them.

Using IPS to protect your web server

Many companies have web servers and they must be protected from attack. Since web servers must be accessible, protection is not as simple as blocking access. IPS is one tool your FortiGate unit has to allow you to protect your network.

In this example, we will configure IPS to protect a web server. As shown below, a FortiGate unit protects a web server and an internal network. The internal network will have its own policies and configuration but we will concentrate on the web server in this example.

A simple network configuration

The FortiGate unit is configured with:

- a virtual IP to give the web server a unique address accessible from the Internet.
- a security policy to allow access to the web server from the Internet using the virtual IP.

To protect the web server using intrusion prevention, you need to create an IPS sensor, populate it with filters, then enable IPS scanning in the security policy.

To create an IPS sensor

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select **Create New**.
3. Enter `web_server` as the name of the new IPS sensor.
4. Select **OK**.

The new IPS sensor is created but it has no filters, and therefore no signatures are included.

The web server operating system is Linux, so you need to create a filter for all Linux server signatures.

To create the Linux server filter

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select the `web_server` IPS sensor and select the **Edit** icon.
3. In the **Pattern Based Signatures and Filters** section, select **Create New**.
4. For **Sensor Type**, select **Filter Based**.
5. For **Filter Options**.
6. In the Filter Options choose the following:
 - a. For **Severity**: select all of the options
 - b. For **Target**: select **server** only.
 - c. For **OS**: select **Linux** only.
7. Select **OK**.

The filter is saved and the IPS sensor page reappears. In the filter list, find the **Linux Server** filter and look at the value in the **Count** column. This shows how many signatures match the current filter settings. You can select the **View Rules** icon to see a listing of the included signatures.

To edit the security policy

1. Go to **Policy & Objects > IPv4 Policy** select security policy that allows access to the web server, and select the **Edit** icon.
2. Enable IPS option and choose the `web_server` IPS sensor from the list.
3. Select **OK**.

Since IPS is enabled and the `web_server` IPS sensor is specified in the security policy controlling the web server traffic, the IPS sensor examines the web server traffic for matches to the signatures it contains.

Create and test a packet logging IPS sensor

In this example, you create a new IPS sensor and include a filter that detects the EICAR test file and saves a packet log when it is found. This is an ideal first experience with packet logging because the EICAR test file can cause no harm, and it is freely available for testing purposes.

Create an IPS sensor

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select **Create New**.
3. Name the new IPS sensor `EICAR_test`.
4. Select **OK**.

Create an entry

1. Select the **Create New**.
2. For **Sensor Type** choose **Specify Signatures**.
3. Rather than search through the signature list, use the name filter by selecting the search icon over the header of the **Signature** column.
4. Enter `EICAR` in the Search field.
5. Highlight the `Eicar.Virus.Test.File` signature by clicking on it.
6. Select **Block** as the **Action** for the `EICAR test` sensor in the **IPS Signatures** table.
7. Enable **Packet Logging**.
8. Select **OK** to save the IPS sensor.

Add the IPS sensor to the security policy allowing Internet access

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select the security policy that allows you to access the Internet.
3. Select the **Edit** icon.
4. Go to **Security Profiles** and enable **IPS** and choose `EICAR test` from the available IPS sensors..
5. Enable **Log Allowed Traffic** and select **All Sessions**.
6. Select **OK**.

With the IPS sensor configured and selected in the security policy, the FortiGate unit blocks any attempt to download the EICAR test file.

Test the IPS sensor

1. Using your web browser, go to http://www.eicar.org/anti_virus_test_file.htm.
2. Scroll to the bottom of the page and select **eicar.com** from the row labeled as using the standard HTTP protocol.
3. The browser attempts to download the requested file and,
 - If the file is successfully downloaded, the custom signature configuration failed at some point. Check the custom signature, the IPS sensor, and the firewall profile.
 - If the download is blocked with a high security alert message explaining that you're not permitted to download the file, the EICAR test file was blocked by the FortiGate unit antivirus scanner before the IPS sensor could examine it. Disable antivirus scanning and try to download the EICAR test file again.
 - If no file is downloaded and the browser eventually times out, the custom signature successfully detected the EICAR test file and blocked the download.

Viewing the packet log

1. Go to **Log & Report > Forward Traffic**.
2. Locate the log entry that recorded the blocking of the EICAR test file block. The Message field data will be `tools: EICAR.AV.Test.File.Download`.
3. Select the **View Packet Log** icon in the **Packet Log** column.
4. The packet log viewer is displayed.

Configuring a Fortinet Security Processing module

The Example Corporation has a web site that is the target of SYN floods. While they investigate the source of the attacks, it's very important that the web site remain accessible. To enhance the ability of the company's FortiGate-100D to deal with SYN floods, the administrator will install an ASM-CE4 Fortinet Security Processing module and have all external access to the web server come through it.

The security processing modules not only accelerate and offload network traffic from the FortiGate unit's processor, but they also accelerate and offload security and content scanning. The ability of the security module to accelerate IPS scanning and DoS protection greatly enhances the defense capabilities of the FortiGate-100D.

Assumptions

As shown in other examples and network diagrams throughout this document, the Example Corporation has a pair of FortiGate-100D units in an HA cluster. To simplify this example, the cluster is replaced with a single FortiGate-100D.

An ASM-CE4 is installed in the FortiGate-100D.

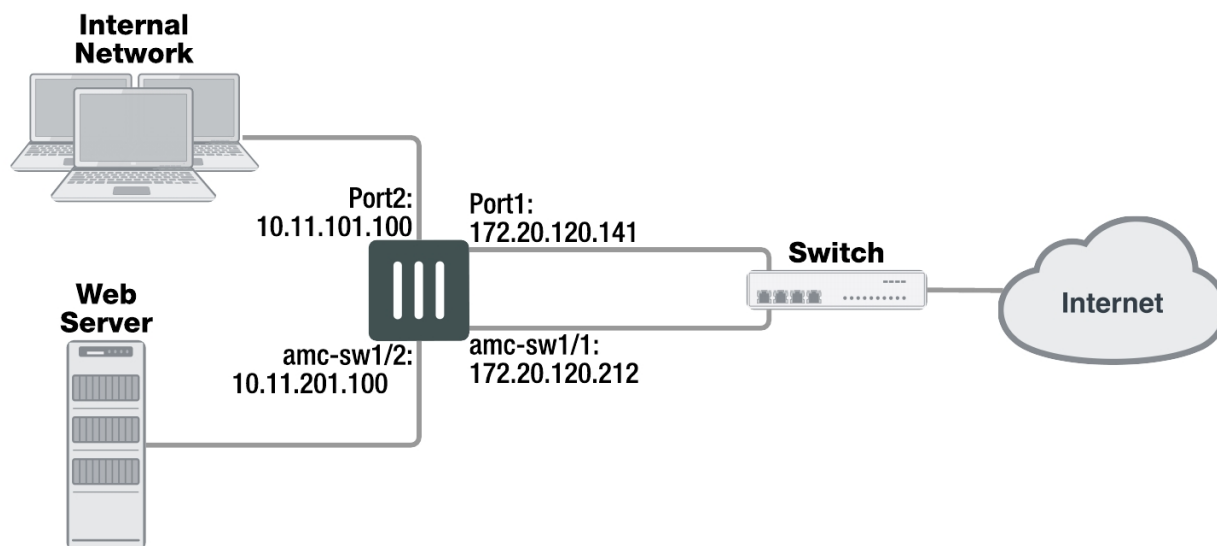

The network is configured as shown below.

Network configuration

The Example Corporation network needs minimal changes to incorporate the ASM-CE4. Interface amc-sw1/1 of the ASM-CE4 is connected to the Internet and interface amc-sw1/1 is connected to the web server.

Since the main office network is connected to port2 and the Internet is connected to port1, a switch is installed to allow both port1 and amc-sw1/1 to be connected to the Internet.

The FortiGate-100D network configuration

The switch used to connect port1 and amc-sw1/1 to the Internet must be able to handle any SYN flood, all of the legitimate traffic to the web site, and all of the traffic to and from the Example Corporation internal network. If the switch can not handle the bandwidth, or if the connection to the service provider can not provide the required bandwidth, traffic will be lost.

Security module configuration

The Fortinet security modules come configured to give equal priority to content inspection and firewall processing. The Example Corporation is using a ASM-CE4 module to defend its web server against SYN flood attacks so firewall processing is a secondary consideration.

Use these CLI commands to configure the security module in ASM slot 1 to devote more resources to content processing, including DoS and IPS, than to firewall processing.

```
config system amc-slot
  edit sw1
    set optimization-mode fw-ips
    set ips-weight balanced
    set ips-p2p disable
    set ips-fail-open enable
    set fp-disable none
    set ipsec-inb-optimization enable
    set syn-proxy-client-timer 3
    set syn-proxy-server-timer 3
  end
```

These settings do not disable firewall processing. Rather, when the security module nears its processing capacity, it will chose to service content inspection over firewall processing.

Anti-spam filter

This section describes how to configure FortiGate email filtering for IMAP, POP3, and SMTP email. Email filtering includes both spam filtering and filtering for any words or files you want to disallow in email messages. If your FortiGate unit supports SSL content scanning and inspection, you can also configure spam filtering for IMAPS, POP3S, and SMTPS email traffic.

The Anti-Spam security profile is only available when operating the FortiGate in proxy-based inspection.

The following topics are included in this section:

Anti-spam concepts

You can configure the FortiGate unit to manage unsolicited commercial email by detecting and identifying spam messages from known or suspected spam servers.

The FortiGuard Anti-Spam service uses both a sender IP reputation database and a spam signature database, along with sophisticated spam filtering tools, to detect and block a wide range of spam messages. Using FortiGuard Anti-Spam profile settings, you can opt to filter with IP address checking, URL checking, email checksum checking, detection of phishing URLs in email, and spam submission. Updates to the IP reputation and spam signature databases are provided continuously via the global FortiGuard Distribution Network.

At the [FortiGuard Anti-Spam](#) service page on the [FortiGuard Labs](#) website, you can find out whether an IP address is blacklisted in the FortiGuard Anti-Spam IP reputation database, or whether a URL or email address is in the signature database.

Anti-spam techniques

The FortiGate unit has a number of techniques available to help detect spam. Some use the FortiGuard Anti-Spam service and require a subscription. The remainder use your DNS servers or use lists that you must maintain.

Black white list

These are the types of black white lists available. They include:

- **IP/Netmask**

The FortiGate unit compares the IP address of the client delivering the email to the addresses in the IP address black / white list specified in the email filter profile. If a match is found, the FortiGate unit will take the action configured for the matching black / white list entry against all delivered email.

The default setting of the `smtp-spamhdrop` CLI command is `disable`. If enabled, the FortiGate unit will check all the IP addresses in the header of SMTP email against the specified IP address black / white list.

- **Email Wildcard**

The FortiGate unit compares the sender email address, as shown in the message header and envelope MAIL FROM, to the pattern in the patterned field. The wildcard symbol is used in the place of characters in the address that may vary from the pattern. If a match is found, the FortiGate unit will take the action configured for the matching black / white list entry.

- **Email Regular Expression**

The FortiGate unit compares the sender email address, as shown in the message envelope MAIL FROM, to the

pattern in the patterned field. The regular expression that can be used is much more sophisticated than a simple wildcard variable. If a match is found, the FortiGate unit will take the action configured for the matching black/white list entry.

Pattern

The pattern field is for entering the identifying information that will enable the filter to correctly identify the email messages.

- If the type is IP/Netmask the filter will be an IP address with a subnet mask.
- If the type is Email Wildcard the filter will be an email address with a wildcard symbol in place of the variable characters. For example *.example.com or fred@*.com.
- If the type is Email Regular Expression, regular expression can be used to create a more granular filter for email addresses. For example, `^[_a-z0-9-]+(\.[_a-z0-9-]+)*@(example|xample|examp).(com|org|net)` could be used filter based on a number of combinations of email domain names.

Action

- **Tag**
If this is the selected action, the email will be allowed through but it will be tagged with an indicator that clearly marks the email as spam.
- **Pass**
If this is the selected action, the email will be allowed to go through to its destination on the assumption that the message is not spam.
- **Discard**
If this is the selected action, the email will be dropped at the before reaching its destination.

Status

Indicates whether this particular list is enabled or disabled.

Banned word check

When you enable banned word checking, your FortiGate unit will examine the email message for words appearing in the banned word list specified in the Anti-Spam profile. If the total score of the banned word discovered in the email message exceeds the threshold value set in the Anti-Spam profile, your FortiGate unit will treat the message as spam.

When determining the banned word score total for an email message, each banned word score is added once no matter how many times the word appears in the message. Use the command `config spamfilter bword` to add an email banned word list. Use the command `config spamfilter profile` to add a banned word list to an Anti-Spam profile.

How content is evaluated

Every time the banned word filter detects a pattern in an email message, it adds the pattern score to the sum of scores for the message. You set this score when you create a new pattern to block content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the total score equals or exceeds the threshold, the email message is considered as spam and treated according to the spam action configured in the email filter profile. The score for each pattern is counted only once, even if that pattern appears many times in the email message. The default score for banned word patterns is 10 and the default threshold is 10. This means that by default, an email message is blocked by a single match.

A pattern can be part of a word, a whole word, or a phrase. Multiple words entered as a pattern are treated as a phrase. The phrase must appear as entered to match. You can also use wildcards or regular expressions to have a pattern match multiple words or phrases.

For example, the FortiGate unit scans an email message that contains only this sentence: “The score for each word or phrase is counted only once, even if that word or phrase appears many times in the email message.”

Banned word pattern	Pattern type	Assigned score	Score added to the sum for the entire page	Comment
word	Wildcard	20	20	The pattern appears twice but multiple occurrences are only counted once.
word phrase	Wildcard	20	0	Although each word in the phrase appears in the message, the words do not appear together as they do in the pattern. There are no matches.
word*phrase	Wildcard	20	20	The wildcard represents any number of any character. A match occurs as long as “word” appears before “phrase” regardless of what is in between them.
mail*age	Wildcard	20	20	Since the wildcard character can represent any characters, this pattern is a match because “email message” appears in the message.

In this example, the message is treated as spam if the banned word threshold is set to 60 or less.

Adding words to a banned word list

When you enter a word, set the `Pattern-type` to wildcards or regular expressions.

Wildcard uses an asterisk (“*”) to match any number of any character. For example, `re*` will match all words starting with “re”.

Regular expression uses Perl regular expression syntax. See <http://perldoc.perl.org/perlretut.html> for detailed information about using Perl regular expressions.

DNS-based Blackhole List (DNSBL)

A DNSBL is a list of IP addresses, usually maintained by a third party, which are identified as being associated with spamming.

FortiGuard Anti-spam Service.

FortiGuard IP address check

The FortiGate unit queries the FortiGuard Anti-Spam Service to determine if the IP address of the client delivering the email is blacklisted. A match will cause the FortiGate unit to treat delivered messages as spam.

The default setting of the `smtp-spamhdrop` CLI command is `disable`. When you enable FortiGuard IP address checking, your FortiGate unit will submit the IP address of the client to the FortiGuard service for

checking. If the IP address exists in the FortiGuard IP address black list, your FortiGate unit will treat the message as spam.

FortiGuard URL check

When you enable FortiGuard URL checking, your FortiGate unit will submit all URLs appearing in the email message body to the FortiGuard service for checking. If a URL exists in the FortiGuard URL black list, your FortiGate unit will treat the message as spam.

FortiGuard email checksum check

When you enable FortiGuard email checksum checking, your FortiGate unit will submit a checksum of each email message to the FortiGuard service for checking. If a checksum exists in the FortiGuard checksum black list, your FortiGate unit will treat the message as spam.

Detect phishing URLs in email

When you enable FortiGuard phishing URL detection, your FortiGate unit will submit all URL hyperlinks appearing in the email message body to the FortiGuard service for checking. If a URL exists in the FortiGuard URL phishing list, your FortiGate unit will remove the hyperlink from the message. The URL will remain in place, but it will no longer be a selectable hyperlink.

FortiGuard spam submission

Spam submission is a way you can inform the FortiGuard Anti-Spam service of non-spam messages incorrectly marked as spam. When you enable this setting, the FortiGate unit adds a link to the end of every message marked as spam. You then select this link to inform the FortiGuard Anti-Spam service when a message is incorrectly marked.

Trusted IP addresses

A list of IP addresses that are trusted by the FortiGate is created. Any email traffic coming in from these IP address will be exempted to perform IP based check, such as DNSBL/RBL, FortiShield SPAM IP or locally defined IP black list check.

If the FortiGate unit sits behind a company's Mail Transfer Units, it may be unnecessary to check email IP addresses because they are internal and trusted. The only IP addresses that need to be checked are those from outside of the company. In some cases, external IP addresses may be added to the list if it is known that they are not sources of spam.

MIME header

This feature filters by the MIME header. MIME header settings are configured in a separate part of the command tree but MIME header filtering is enabled within each profile.

HELO DNS lookup

Whenever a client opens an SMTP session with a server, the client sends a HELO command with the client domain name. The FortiGate unit takes the domain name specified by the client in the HELO and does a DNS lookup to determine if the domain exists. If the lookup fails, the FortiGate unit determines that any messages delivered during the SMTP session are spam.

The HELO DNS lookup is available only for SMTP traffic.

Return email DNS check

The FortiGate unit performs a DNS lookup on the If no such record exists, the message is treated as spam.

When you enable return email DNS checking, your FortiGate unit will take the domain in the reply-to email address and reply-to domain and check the DNS servers to see if there is an A or MX record for the domain. If the domain does not exist, your FortiGate unit will treat the message as spam.

Configuring Anti-spam

FortiGuard email filtering techniques us FortiGuard services to detect the presence of spam among your email. A FortiGuard subscription is required to use the FortiGuard email filters. To enable email filtering an email filter needs to be created and then the filter needs to be associated with a security policy.

The Anti-Spam security profile is only available when operating the FortiGate in proxy-based inspection.

The filter can be created as follows:

- Go to **Security Profiles > Anti-Spam**.
 - Select the **Create New** icon (a plus symbol in a circle in the upper right hand corner).
 - Select the **List** icon (a page symbol in the upper right hand corner) and in the new window select **Create New**.

An existing filter can be edited as follows:

- Go to **Security Profiles > Anti-Spam**.
 - Select the filter that you wish to edit from the dropdown menu in the upper right corner.
 - Select the List icon (a page symbol in the upper right hand corner) and select the filter that you wish to edit from the list.

Once you are in the proper **Edit Anti-Spam Profile** window, you can enter a name in the Name field if it's a new filter.

The Comments field is for a description or other information that will assist in understanding the function or purpose of the this particular filter.

Before any of the other features or options of the filter appear the checkbox next to Enable Spam Detection and Filtering must be checked.

Spam detection by protocol

This matrix includes three rows that represent the email protocols IMAP, POP3 and SMTP.

There are also columns for:

Spam Action

For the client protocols, IMAP and POP3 the options are:

- **Tag** - This action will insert a tag into the email somewhere so that when the recipients view the email they will be warned that it is likely a spam.
- **Pass** - This action will allow any emails marked as spam to pass through without change. If this option is chosen, the Tag comments will be greyed out.

For the transfer protocol, SMTP, the options are:

- **Tag** - This action will insert a tag into the email somewhere so that when the recipients view the email they will be warned that it is likely a spam.
- **Discard** - The action will drop the email before it reaches its destination.
- **Pass** - This action will allow any emails marked as spam to pass through without change. If this option is chosen, the Tag comments will be greyed out.

Tag Location

- **Subject** - The contents of the Tag Format will be inserted into the subject line. The subject line is the most commonly used.
- **MIME** - The contents of the Tag Format will be inserted in with the MIME header header.

Tag Format

The contents of this field will be entered into the tag location specified. The most common tag is something along the lines of [Spam] or **SPAM**

FortiGuard spam filtering

The options in the section are ones that require a FortiGuard subscription.

The options available in this section, to be selected by checkbox are:

- IP Address Check
- URL Check
- Detect Phishing URLs in Email
- Email Checksum Check
- Spam Submission

Local spam filtering

The options in the section are ones can be managed on the local device without the need for a FortiGuard subscription.

The options available in this section, to be selected by checkbox are:

- HELO DNS Lookup
- Return Email DNS Check
- Black White List - checking this option will produce a table that can be edited to create a number of black / white lists that can be separately configured and enabled.

Another local spam filter profile option that can only be configured in the CLI is the `bannedword.check`. To configure this, enter the following commands in the CLI:

```
config spamfilter profile
  edit <filter_name>
    set options bannedword
    set spam-bword-table 1
  next
end
```

See the section on [banned word checking](#) for more information on how content is evaluated.

Order of spam filtering

The FortiGate unit checks for spam using various filtering techniques. The order in which the FortiGate unit uses these filters depends on the mail protocol used.

Filters requiring a query to a server and a reply (FortiGuard Anti-Spam service and DNSBL/ORDBL) are run simultaneously. To avoid delays, queries are sent while other filters are running. The first reply to trigger a spam action takes effect as soon as the reply is received.

Each spam filter passes the email to the next if no matches or problems are found. If the action in the filter is **Mark as Spam**, the FortiGate unit tags the email as spam according to the settings in the email filter profile.

For SMTP and SMTPS, if the action is **Discard**, the email message is discarded or dropped.

If the action in the filter is **Mark as Clear**, the email is exempt from any remaining filters. If the action in the filter is **Mark as Reject**, the email session is dropped.

Order of SMTP and SMTPS spam filtering

The FortiGate unit scans SMTP and SMTPS email for spam in a specific order, depending on whether or not the local override feature has been enabled. By default, local override is disabled on the FortiGate. Enabling local override will give priority to local spam filters.

You can enable local override with the CLI command `set local-override {enable | disable}` when configuring a spamfilter profile. Enable this command to override SMTP or SMTPS remote check, which includes IP RBL check, IP FortiGuard AntiSpam check and HELO DNS check, with the locally defined black/white antispam list.

SMTPS spam filtering is available on FortiGate units that support SSL content scanning and inspection.

Enabling local override of Anti-Spam filter

CLI Syntax

```
config spamfilter profile
  edit <filter_name>
    set spam-filtering enable
    set options spambwl spamfsip spamfsurl spamhelodns spamfsphish
    config smtp
      set local-override enable
    end
    set spam-bwl-table 1
  next
end
```

Order of SMTP and SMTPS spam filtering with local-override disabled

1. HELO DNS Lookup, Last Hop IP check against ORDBL
2. Return email DNS check, FortiGuard email checksum check, FortiGuard URL check, FortiGuard IP address check, Phishing URLs detection
3. Last Hop IP check local black/white list (BWL)
4. Envelope Address check local BWL
5. Headers IPs local BWL

6. Headers email address local BWL, MIME header checks based on local list of patterns (mheader)
7. Banned words (subject first, then body) based on local BWL (bword)

Order of SMTP and SMTPS spam filtering with local-override enabled

1. Last Hop IP check local black/white list (BWL)
2. Envelope Address check local BWL
3. Headers IPs local BWL, MIME header checks based on local list of patterns (mheader)
4. Headers email address local BWL
5. Banned words (subject first, then body) based on local list of patterns (bword)
6. HELO DNS Lookup, Last Hop IP check against ORDBL
7. Return email DNS check, FortiGuard email checksum check, FortiGuard URL check, FortiGuard IP address checks, Phishing URLs detection

Order of IMAP, POP3, IMAPS and POP3S spam filtering

The FortiGate unit scans IMAP, POP3, IMAPS and POP3S email for spam in the order given below. IMAPS and POP3S spam filtering is available on FortiGate units that support SSL content scanning and inspection.

1. MIME headers check, E-mail address BWL check
2. Banned word check on email subject
3. IP BWL check
4. Banned word check on email body
5. Return email DNS check, FortiGuard Antispam email checksum check, FortiGuard Antispam URL check, DNSBL & ORDBL check.

Spam actions

When spam is detected, the FortiGate unit will deal with it according to the **Spam Action** setting in the anti-spam profile. Note that POP3S, IMAPS and SMTPS spam filtering is available only on FortiGate units that support SSL content scanning and inspection. POP3, IMAP, POP3S and IMAPS mail can only be tagged. SMTP and SMTPS mail can be set to **Discard** or **Tagged**:

Discard

When the spam action is set to **Discard**, messages detected as spam are deleted. No notification is sent to the sender or recipient.

Pass

When the spam action is set to **Pass**, the spam filter is disabled for the related protocol.

Tag

When the spam action is set to **Tag**, messages detected as spam are labeled and delivered normally. The text used for the label is set in the **Tag Format** field and the label is placed in the subject or the message header, as set with the **Tag Location** option.

Anti-spam examples

Configuring simple Anti-spam protection

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable Anti-Spam protection on a FortiGate unit located in a satellite office.

Creating an email filter profile

Most Anti-Spam settings are configured in an Anti-Spam profile. Anti-Spam profiles are selected in firewall policies. This way, you can create multiple Anti-Spam profiles, and tailor them to the traffic controlled by the security policy in which they are selected. In this example, you will create one Anti-Spam profile.

To create an Anti-Spam profile — web-based manager

1. Go to **Security Profiles > Anti-Spam**.
2. Select the **Create New** icon in the Edit Anti-Spam Profile window title.
3. In the **Name** field, enter `basic_anti-spam`.
4. Select **Enable Spam Detection and Filtering**.
5. Ensure that **IMAP**, **POP3**, and **SMTP** are selected in the header row.
These header row selections enable or disable examination of each Anti-Spam type. When disabled, the email traffic of that type is ignored by the FortiGate unit and no Anti-Spam options are available.
6. Under **FortiGuard Spam Filtering**, enable **IP Address Check**.
7. Under **FortiGuard Spam Filtering**, enable **URL Check**.
8. Under **FortiGuard Spam Filtering**, enable **E-mail Checksum Check**.
9. Select **OK** to save the email filter profile.

To create an Anti-spam profile — CLI

```
config spamfilter profile
  edit basic_anti-spam
    set options spamfsip spamfsurl spamfschksum
  end
```

Selecting the Anti-spam profile in a security policy

An Anti-Spam profile directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an Anti-Spam profile is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the Anti-Spam profile in a security policy — web-based manager

1. Go to **Policy & Objects > IPv4 Policy**.
2. Create a new or edit a policy.
3. Turn on Anti-Spam.
4. Select the `basic_anti-spam` profile from the list.
5. Select **OK** to save the security policy.

To select the Anti-spam profile in a security policy — CLI

```
config firewall policy
  edit 1
    set utm-status enable
    set profile-protocol-options default
    set spamfilter-profile basic_anti-spam
  end
```

IMAP, POP3, and SMTP email traffic handled by the security policy you modified will be scanned for spam. Spam messages have the text “Spam” added to their subject lines. A small office may have only one security policy configured. If you have multiple policies, consider enabling spam scanning for all of them.

Blocking email from a user

Employees of the Example.com corporation have been receiving unwanted email messages from a former client at a company called example.net. The client’s email address is client@example.net. All ties between the company and the client have been severed, but the messages continue. The FortiGate unit can be configured to prevent these messages from being delivered.

To enable Anti-Spam

1. Go to **Security Profiles > Anti-Spam**.
2. Select the Anti-Spam profile that is used by the firewall policies handling email traffic from the Anti-Spam profile drop down list.
3. In the row **Tag Location**, select **Subject** for all three mail protocols.
4. In the row **Tag Format**, enter `SPAM:` in all three fields.
This means that normal spam will be tagged in the subject line.
5. Select **Enable Spam Detection and Filtering**.
6. Under **Local Spam Filtering**, enable **Black White List** and select **Create New**.
7. In the Black White List widget, select **Create New**.
8. Select **Email Address Wildcard**.
9. Enter `client@example.net` in the **Pattern** field.
 - If you wanted to prevent everyone’s email from the client’s company from getting through you could have used `*@example.net` instead.
10. Set the **Action** as **Mark as Spam**.
11. Set the **Status** to **Enable**.
12. Confirm that the SMTP protocol action is set to **Discard**.
13. Select **OK**.

Now that the email address list is created, you must enable the email filter in the Anti-Spam profile.

When this Anti-Spam profile is selected in a security policy, the FortiGate unit will reject any email message from an address ending with `@example.net` for all email traffic handled by the security policy.

Data leak prevention

The FortiGate data leak prevention (DLP) system allows you to prevent sensitive data from leaving your network. When you define sensitive data patterns, data matching these patterns will be blocked, or logged and allowed, when passing through the FortiGate unit. You configure the DLP system by creating individual filters based on file type, file size, a regular expression, an advanced rule, or a compound rule, in a DLP sensor and assign the sensor to a security policy.

Although the primary use of the DLP feature is to stop sensitive data from leaving your network, it can also be used to prevent unwanted data from entering your network and to archive some or all of the content passing through the FortiGate unit.

This section describes how to configure the DLP settings. DLP can only be configured for FortiGate units in proxy-based inspection.

The following topics are included:

- [Data leak prevention concepts](#)
- [Enable data leak prevention](#)
- [Creating or editing a DLP sensor](#)
- [DLP archiving](#)
- [DLP examples](#)

Data leak prevention concepts

Data leak prevention examines network traffic for data patterns you define through the use of the GUI and CLI commands. The DLP feature is broken down into a number of parts. Note, DLP is not available in flow-based inspection.

DLP sensor

A DLP sensor is a package of filters. To use DLP, you must enable it in a security policy and select the DLP sensor to use. The traffic controlled by the security policy will be searched for the patterns defined in the filters contained in the DLP sensor. Matching traffic will be passed or blocked according to how you configured the filters.

DLP filter

Each DLP sensor has one or more filters configured within it. Filters can examine traffic for known files using DLP fingerprints, for files of a particular type or name, for files larger than a specified size, for data matching a specified regular expression, or for traffic matching an advanced rule or compound rule.

DLP filter actions

You can configure the action taken when a match is detected. The actions include:

- Allow
- Log Only
- Block
- Quarantine IP address

Log Only is enabled by default.

Allow

No action is taken even if the patterns specified in the filter are matched.

Log Only

The FortiGate unit will take no action on network traffic matching a rule with this action. The filter match is logged, however. Other matching filters in the same sensor may still operate on matching traffic.

Block

Traffic matching a filter with the block action will not be delivered. The matching message or download is replaced with the data leak prevention replacement message.

Quarantine IP Address/ Source IP ban

Starting in FortiOS 5.2, the quarantine, as a place where traffic content was held in storage so it couldn't interact with the network or system, was removed. The term quarantine was kept to describe preventing selected source IPs from interacting with the network and protected systems. This source IP ban is kept in the kernel rather than in any specific application engine and can be queried by APIs. The features that can use the APIs to access and use the banned source IP addresses are antivirus, DLP, DoS and IPS. Both IPv4 and IPv6 version are included in this feature.

If the **quarantine-ip** action is used, the additional variable of expiry time will become available. This variable determines for how long the source IP address will be blocked. In the GUI it is shown as a field before minutes. In the CLI the option is called `expiry` and the duration is in the format `<###d##h##m>`. The maximum days value is 364. The maximum hour value is 23 and the maximum minute value is 59. The default is 5 minutes.

If a DLP sensor has contains a DLP filter with action set to **Allow** certain files and another DLP filter with action set to **Block** those same files, then the order of the filters within that sensor will determine which action is taken first.

Configuring using the CLI

To configure the DLP sensor to add the source IP address of the sender of a protected file to the quarantine or list of banned source IP addresses edit the DLP Filter, use these CLI commands:

```
config dlp sensor
  edit <sensor name>
    config filter
      edit <id number of filter>
        set action quarantine-ip
        set expiry 5m
      end
    end
  end
```

Preconfigured sensors

A number of preconfigured sensors are provided with your FortiGate unit. These can be edited to more closely match your needs.

Two of the preconfigured sensors with filters ready for you to enable are:

- Credit-Card - This sensor logs the traffic, both files and messages, that contain credit card numbers in the formats used by American Express, MasterCard and Visa.
- SSN-Sensor - This sensor logs the traffic, both files and messages, that contain Social Security Numbers with the exception of those that are WebEx invitation emails.

These rules affect only unencrypted traffic types. If you are using a FortiGate unit that can decrypt and examine encrypted traffic, you can enable those traffic types in these rules to extend their functionality if required.

Before using the rules, examine them closely to ensure you understand how they will affect the traffic on your network.

DLP document fingerprinting

One of the DLP techniques to detect sensitive data is fingerprinting (also called document fingerprinting). Most DLP techniques rely on you providing a characteristic of the file you want to detect, whether it's the file type, the file name, or part of the file contents. Fingerprinting is different in that you provide the file itself. The FortiGate unit then generates a checksum fingerprint and stores it. The FortiGate unit generates a fingerprint for all files detected in network traffic, and it is compared to all of the fingerprints stored in its fingerprint database. If a match is found, the configured action is taken.

The document fingerprint feature requires a FortiGate unit with internal storage.

Any type of file can be detected by DLP fingerprinting and fingerprints can be saved for each revision of your files as they are updated.

To use fingerprinting you:

- select the documents to be fingerprinted
- add fingerprinting filters to DLP sensors
- add the sensors to firewall policies that accept the traffic to which to apply fingerprinting.

Fingerprinting

Fingerprint scanning allows you to create a library of files for the FortiGate unit to examine. It will create checksum fingerprints so each file can be easily identified. Then, when files appear in network traffic, the FortiGate will generate a checksum fingerprint and compare it to those in the fingerprint database. A match triggers the configured action.

You must configure a document source or uploaded documents to the FortiGate unit for fingerprint scanning to work.

Fingerprinted documents

The FortiGate unit must have access to the documents for which it generates fingerprints.

Configuring the document source

To configure a DLP fingerprint document source in FortiOS 5.6.0, you must use CLI commands.

```
config dlp fp-doc-source
```

```
edit <name_str>
  set name <string>
  set server-type {smb}
  set server <string>
  set period {none | daily | weekly | monthly}
  set vdom {mgmt | current}
  set scan-subdirectories {enable | disable}
  set remove-deleted {enable | disable}
  set keep-modified {enable | disable}
  set username <string>
  set password <password>
  set file-path <string>
  set file-pattern <string>
  set sensitivity <string>
  set tod-hour <integer>
  set tod-min <integer>
  set weekday {sunday | monday | tuesday | wednesday | thursday | friday | saturday}
  set date <integer>
end
```

Configuring a DLP fingerprint sensor

To configure a DLP fingerprint sensor in FortiOS 5.6.0, you must use CLI commands.

```
config dlp sensor
  edit <sensor name>
    config filter
      edit <id number of filter>
        set proto {smtp | pop3 | imap http-get | http-post | ftp | nntp | mapi}
        set filter-by fingerprint
        set fp-sensitivity { critical | private | warning}
        set action {allow | log-only | block | ban | quarantine-ip | quarantine-
          port}
      next
    end
  next
```

Once you have set the document source and configured the DLP sensor for fingerprinting, add the DLP sensor to the applicable firewall policy. This can be done through the GUI.

File size

This filter-type checks for files exceeding a configured size. All files larger than the specified size are subject to the configured action. The value of the field is measured in kilobytes (KB).

DLP filtering by specific file types

File filters use file filter lists to examine network traffic for files that match either file names or file types. For example, you can create a file filter list that will find files called secret.* and also all JPEG graphic files. You can create multiple file filter lists and use them in filters in multiple DLP sensors as required.

Specify File Types is a DLP option that allows you to block files based on their file name or their type.

- **File types** are a means of filtering based on examination of the file contents, regardless of the file name. If you block the file type **Archive (zip)**, all zip archives are blocked even if they are renamed with a different file extension. The FortiGate examines the file contents to determine what type of file it is and then acts accordingly.
- **File Name patterns** are a means of filtering based purely on the names of files. They may include wildcards (*). For example, blocking *.scr will stop all files with an .scr file extension, which is commonly used for Windows screen saver files. Files trying to pass themselves off as Windows screen saver files by adopting the file-naming convention will also be stopped.
 - Files can specify the full or partial file name, the full or partial file extension, or any combination. File pattern entries are not case sensitive. For example, adding *.exe to the file pattern list also blocks any files ending with .exe.
 - Files are compared to the enabled file patterns from top to bottom, in list order.

If DLP detects a file inside an archive that should be blocked, the entire archive will be blocked.

Watermarking

Watermarking is essentially marking files with a digital pattern to mark the file as being proprietary to a specific company. Fortinet provides a Linux-based utility that applies a digital watermark to files. The utility adds a small (approx. 100 byte) pattern to the file that is recognized by the DLP watermark filter. The pattern is invisible to the end user.

When watermarking a file it should be verified that the pattern matches up to a category found on the FortiGate firewall. For example, if you are going to watermark a file with the sensitivity level of “Secret” you should verify that “Secret” is a sensitivity level that has been assigned in the FortiGate unit.

Watermark Sensitivity

If you are using watermarking on your files you can use this filter to check for watermarks that correspond to sensitivity categories that you have set up.

The Corporate Identifier is to make sure that you are only blocking watermarks that your company has place on the files, not watermarks with the same name by other companies.

Software Versions

Before planning on using watermarking software it is always best to verify that the software will work with your OS. Currently, the only utility available to watermark files is a Linux-based command line tool. It is available for download from the [Fortinet Customer Service & Support](#) website, with a valid support contract and access to the site. To access the file:

1. Sign into the [Fortinet Customer Service & Support](#) website.
2. Go to <https://support.fortinet.com/Download/FirmwareImages.aspx>.
3. Navigate to the image file path for /FortiGate / v5.00 / 5.0 / WATERMARK
4. Download the file **fortinet-watermark-linux.out**.

File types

The watermark utility does not work with every file type. The following file types are supported by the watermark tool: .txt; .pdf; .doc; .xls; .ppt; .docx; pptx; and, .xlsx.

Syntax of the watermark utility

The tool is executed in a Linux environment by passing in files or directories of files to insert a watermark.

USAGE:

```
watermark_linux_amd64 <options> -f <file name> -i <identifier> -l <sensitivity level>
watermark_linux_amd64 <options> -d <directory> -i <identifier> -l <sensitivity level>
```

Options:

```
-h print help
-I inplace watermarking (don't copy file)
-o output file (or directory in directory mode)
-e encode <to non-readable>
-i add watermark identifier
-l add watermark sensitivity level
-D delete watermark identifier
-L delete watermark sensitivity level
```

Regular expression

The FortiGate unit checks network traffic for the regular expression specified in a regular expression filter. The regular expression library used by Fortinet is a variation of a library called PCRE (Perl Compatible Regular Expressions). A number of these filters can be added to a sensor making a sort of 'dictionary' subset within the sensor.

Some other, more limited DLP implementations, use a list of words in a text file to define what words are searched for. While the format used here is slightly different than what some people are used to, the resulting effect is similar. Each regular expression filter can be thought of as a more versatile word to be searched against. In this dictionary (or sensor), the list of words is not limited to just predefined words. It can include expressions that accommodate complex variations on those words and even target phrases. Another advantage of the individual filter model of this dictionary over the list is that each word can be assigned its own action, making this implementation much more granular.

Encrypted

This filter is a binary one. If the file going through the policy is encrypted the action is triggered.

Examining specific services

To assist in optimizing the performance of the firewall, the option exists to select which services or protocol traffic will be checked for the targeted content. This setting gives you a tool to save the resources of the FortiGate unit by only using processing cycles on the relevant traffic. Just check the boxes associated with the service / protocol that you want to have checked for filter triggers.

Enable data leak prevention

DLP examines your network traffic for data patterns you specify. The FortiGate unit then performs an action based on the which pattern is found and a configuration set for each filter trigger.

DLP is not available in flow-based inspection.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. [Create a DLP sensor](#).
New DLP sensors are empty. You must create one or more filters in a sensor before it can examine network traffic.
2. Add one or more filters to the DLP sensor.
Each filter searches for a specific data pattern. When a pattern in the active DLP sensor appears in the traffic, the FortiGate unit takes the action configured in the matching filter. Because the order of filters within a sensor cannot be changed, you must configure DLP in sequence.
3. Add the DLP sensor to one or more firewall policies that control the traffic to be examined.

Creating/editing a DLP sensor

DLP sensors are collections of filters. You must also specify an action for the filter when you create it in a sensor. Once a DLP sensor is configured, you add it to a security policy profile. Any traffic handled by that security policy will be examined according to the DLP sensor configuration.

DLP is not available in flow-based inspection.

To create/edit a DLP sensor in the GUI

1. Go to **Security Profiles > Data Leak Prevention**.
2. Choose whether you want to edit an existing sensor or create a new one.
 - The default sensor is the one displayed by default.
 - To edit an existing sensor, select it by either using the drop down menu in the upper right hand corner of the window or by selecting the **List** icon (the furthest right of the 3 icons in the upper right of the window, resembling a page with some lines on it), and then selecting the profile you want to edit from the list.
 - To create a new sensor, select the **Create New** icon (a plus sign within a circle) or the List icon and then select the Create New link in the upper left corner of the window that appears.
3. Enter a name in the **Name** field for any new DLP sensors.
4. Optionally, you may also enter a comment. The comment appears in the DLP sensor list and can remind you of the details of the sensor.
5. At this point you can add filters to the sensor (see adding filters to a DLP sensor) or select **OK** to save the sensor. Without filters, the DLP sensor will do nothing.

Adding filters to a DLP sensor

Once you have created a DLP sensor, you need to add filters.

1. To add filters to a DLP sensor
2. Go to **Security Profiles > Data Leak Prevention**.
3. Select the sensor you wish to edit using the drop-down menu or the sensor list window.
4. Within the Edit DLP Sensor window select **Create New**. A New Filter window should pop up.
5. Select the type of filter. You can choose either **Messages** or **Files**, depending on which of these two are chosen different options will be available.

Message filter will have these configuration options:

- [radio button] Containing: [drop-down menu including: Credit Card # or SSN]
- [radio button] Regular Expression [input field]

Examine the following services:

Web Access

- HTTP-POST

Email

- [check box] SMTP
- [check box] POP3
- [check box] IMAP
- [check box] MAPI

Others

- [check box] NNTP

Action [from drop-down menu]

- Allow
- Log Only (default)
- Block
- Quarantine IP address

Files filter will allow you to choose one of these options:

- **Containing:** drop-down menu including: Credit Card # or SSN
- **File Size** > []KB files greater than the number of KB entered
- Specify File Types
File Types: ["Click to add..."drop-down menu of File extensions]
File Name Patterns:["Click to add..."drop-down menu]
- [radio button] Regular Expression [input field]
- [radio button] Encrypted

Examine the following Services:

Web Access

- [check box] HTTP-POST
- [check box] HTTP-GET

Email

- [check box] SMTP
- [check box] POP3
- [check box] IMAP
- [check box] MAPI

Others

- [check box] FTP
- [check box] NNTP

Action [from drop-down menu]

- Allow
 - Log Only (default)
 - Block
 - Quarantine IP address
6. Select **OK**.
 7. Repeat Steps 6 and 7 for each filter.
 8. Select **Apply** to confirm the settings of the sensor.

If you have configured DLP to block IP addresses and if the FortiGate unit receives sessions that have passed through a NAT device, all traffic from that NAT device — not just traffic from individual users — could be blocked. You can avoid this problem by implementing authentication.

To view or modify the replacement message text, go to **System > Replacement Messages**.

DLP archiving

DLP is typically used to prevent sensitive information from getting out of your company network, but it can also be used to record network use. This is called DLP archiving. The DLP engine examines email, FTP, NNTP, and web traffic. Enabling archiving for rules when you add them to sensors directs the FortiGate unit to record all occurrences of these traffic types when they are detected by the sensor.

Since the archive setting is configured for each rule in a sensor, you can have a single sensor that archives only the things you want.

You can archive Email, FTP, HTTP, and session control content:

- Email content includes IMAP, POP3, and SMTP sessions. Email content can also include email messages tagged as spam by Email filtering. If your unit supports SSL content scanning and inspection, email content can also include IMAPS, POP3S, and SMTPS sessions.
- HTTP content includes HTTP sessions. If your unit supports SSL content scanning and inspection HTTP content can also include HTTPS sessions.

DLP archiving comes in two forms: **Summary** and **Full**.

Summary archiving records information about the supported traffic types. For example, when an email message is detected, the sender, recipient, message subject, and total size are recorded. When a user accesses the Web, every URL the user visits recorded. The result is a summary of all activity the sensor detected.

For more detailed records, use full archiving. When an email message is detected, the message itself, including any attachments, is archived. When a user accesses the Web, every page the user visits is archived. Far more detailed than a summary, full DLP archives require more storage space and processing.

Because both types of DLP archiving require additional resources, DLP archives are saved to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service (subscription required).

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service. DLP archiving is available for FortiAnalyzer when you add a

FortiAnalyzer unit to the Fortinet configuration. The FortiGuard Analysis server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

Two sample DLP sensors are provided with DLP archiving capabilities enabled. If you select the `Content_Summary` sensor in a security policy, it will save a summary DLP archive of all traffic the security policy handles. Similarly, the `Content_Archive` sensor will save a full DLP archive of all traffic handled the security policy you apply it to. These two sensors are configured to detect all traffic of the supported types and archive them. You can see these sensors in the GUI but the configuration is only visible through the CLI; DLP archiving is set in the CLI only.

To set the archive to Summary

```
config dlp sensor
  edit <name of sensor>
    set summary-proto smtp pop3 imap http ftp nntp msn yahoo mapi
  end
```

To set the archive to Full

```
config dlp sensor
  edit <name of sensor>
    set full-archive-proto smtp pop3 imap http ftp nntp msn yahoo mapi
  end
```

If you set the `full-archive-proto` filter to include one or more of the protocols set by the `proto` option, then the archive action is disabled.

DLP examples

You can configure DLP sensors and filters when your FortiGate is operating in proxy-based inspection.

- [Blocking content with credit card numbers](#)
- [Blocking emails larger than 15 MB and logging emails from 5 MB to 15 MB](#)
- [Blocking selectively based on a fingerprint](#)

Blocking content with credit card numbers

When the objective is to block credit card numbers one of the important things to remember is that two filters will need to be used in the sensor. One filter is to prevent sensitive files from being leaked and another is to retain any sensitive data that is not a file (for example, messages or email content).

In the default Credit-Card sensor, you will notice a few things.

- The **Action** is set to **Log Only**
- In the **Files** filter not all of the services are being examined.

If you wish to block as much content as possible with credit card numbers in it instead of just logging most the traffic that has it, the existing sensor will have to be edited.

1. Go to **Security Profiles > Data Leak Prevention**.

Some configurations will have a preconfigured Credit Card sensor where you can use the drop down menu to select **Credit-Card**. If your configuration doesn't already have one create a new sensor.

2. Use the **Create New** icon to add a new sensor.
3. *Create/edit the first filter.* Set **Type** to **Messages** and select **Containing Credit Card #**.
4. Go to **Examine the Following Services** and select all services .
5. Set **Action** to **Block**.
6. Select **OK** or **Apply**.
7. *Create/edit the second filter.* Set **Type** to **Files** and select **Containing Credit Card #**.
8. Go to **Examine the Following Services** and select all services .
9. Set **Action** to **Block**.
10. Select **OK** or **Apply**.
11. Edit the appropriate policies so that under **Security Profiles**, **DLP** is turned on and the **Credit-Card** sensor is selected.

Blocking emails larger than 15 MB and logging emails from 5 MB to 15 MB

Multiple filters will have to be used in this case and the order that they are used is important. Because there is no mechanism to move the filters within the sensor the order that they are added to the sensor is important.

1. Go to **Security Profiles > Data Leak Prevention**.
2. Use the **Create New** icon to add a new sensor. Give it a descriptive **Name**, such as *block_large_emails*. Optionally, enter a descriptive comment.

Once the sensor has been created, a new filter will need to be added.

3. *Create the filter to block the emails over 15 MB.* In the filters table select **Create New**.
4. Set **Type** to **Messages** and enter 15360 in the field next to **File size over**. (1MB = 1024KB, 15 MB = 15 x 1024KB = 15360KB)
5. Go to **Examine the Following Services** and select all **Email** services .
6. Set **Action** to **Block**.
7. Select **OK**.
8. *Create the filter to log emails between 5 MB and 10 MB.* In the filters table select **Create New**.
9. Set **Type** to **Files**.
10. Enter 5120 in the field next to **File size over**. (1MB = 1024KB, 5 MB = 5 x 1024KB = 5124KB)
11. Go to **Examine the Following Services** and select all the email services .
12. Set action to **Log Only**.
13. Select **OK**.

The reason that the block filter is placed first is because the filters are applied in sequence and once the traffic triggers a filter, the action is applied and then the traffic is passed on to the next test. If the Log Only filter which checks for anything over 1MB is triggered this would include traffic over 15MB, so a 16 MB file would only be logged. In the described order, the 16 MB file will be blocked and the 3 MB file will be logged.

Blocking selectively based on a fingerprint

The following is a fairly complex example but shows what can be done by combining various components in the correct configuration.

The company has a number of copyrighted documents that it does not want “escaping” to the Internet but it does want to be able to send those documents to the printers for turning into hardcopy.

The policies and procedures regarding this issue state that:

- Only members of the group **Senior_Editors** can send copyrighted material to the printers.
- Every member of the company by default is included in the group **employees**.
- Even permitted transmission of copyrighted material should be recorded.
- All of the printers IP addresses are in a group called **approved_printers**.
- There is a file share called **copyrighted** where any file that is copyrighted is required to have a copy stored.
- It doesn't happen often but for legal reasons sometimes these files can be changed, but all versions of a file in this directory need to be secured.
- All network connections to the Internet must have AntiVirus enabled using at least the default profile.
- The SSL/SSH Inspection profile used will be **default**.

It is assumed for the purposes of this example that:

- Any addresses or address groups have been created.
- User accounts and groups have been created.
- The account used by the FortiGate is fgtaccess.
- The copyrighted sensitivity level needs to be created.
- The copyrighted material is stored at \\192.168.27.50\books\copyrighted\

1. Add a new Sensitivity Level by running the following commands in the CLI:

```
config dlp fp-sensitivity
  edit copyrighted
end
```

2. Apply files to the fingerprint database by running these commands in the CLI:

```
config dlp fp-doc-source
  edit "copyrighted_material"
    set server-type smb
    set server 192.168.27.50
    set username fgtaccess
    set password *****
    set file-path books/copyrighted/
    set file-pattern *.pdf
    set sensitivity copyrighted
    set period daily
    set tod-hour 2
    set tod-min 0
    set scan-subdirectories enable
    set remove-deleted disable
    set keep-modified enable
  next
end
```

Two Sensors need to be created. One for blocking the transmission of copyrighted material and a second for allowing the passing of copyrighted material under specific circumstances.

3. Create the first DLP Sensor with the following commands in CLI:

```
config dlp sensor
  edit block_copyrighted
```

```

config filter
  edit 1
    set proto smtp pop3 imap http-get http-post ftp nntp mapi
    set filter-by fingerprint
    set fp-sensitivity copyrighted
    set action block
  next
end
next

```

4. Create the second DLP Sensor

```

config dlp sensor
  edit allow_copyrighted
    config filter
      edit 2
        set proto smtp pop3 imap http-get http-post ftp nntp mapi
        set filter-by fingerprint
        set fp-sensitivity copyrighted
        set action log-only
      next
    end
  next

```

5. Create a policy to allow transmission of copyrighted material.

- a. Go to **Policy & Objects > IPv4 Policy**.
- b. Select **Create New**.
- c. Use the following values in the policy:

Incoming Interface	LAN
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	all
Action	ACCEPT
Enable NAT	enabled -- Use Destination Interface Address
AntiVirus	<ON> default
DLP	<ON> Copyrighted
SSL/SSH Inspection	<ON> default
Enable this policy	<ON>

This policy should be placed as close to the beginning of the list of policies so the it is among the first

tested against.

6. Create a policy to block transmission of copyrighted material.

This will in effect be the default template for all following policies in that they will have to use the DLP profile that blocks the transmission of the copyrighted material.

- a. Go to **Policy & Objects > IPv4 Policy**.

- b. Select **Create New** or Edit an existing policy.

- c. Use the following values in the Policy:

The fields should include what ever values you need to accomplish your requirements are but each policy should include the DLP sensor block_copyrighted. Alternatively, if a different DLP configuration is required it should include a filter that blocks **copyrighted** fingerprinted file.

If you need to create a policy that is identity based make sure that there is an Authentication rule for the group **employees** that uses the DLP sensor that blocks copyrighted material.

ICAP support

ICAP is the acronym for Internet Content Adaptation Protocol. The purpose of the feature is to offload work that would normally take place on the firewall to a separate server specifically set up for the specialized processing of the incoming traffic. This takes some of the resource strain off of the FortiGate firewall leaving it to concentrate its resources on things that only it can do.

Offloading value-added services from Web servers to ICAP servers allows those same web servers to be scaled according to raw HTTP throughput versus having to handle these extra tasks.

ICAP servers are focused on a specific function, for example:

- Ad insertion
- Virus scanning
- Content translation
- HTTP header or URL manipulation
- Language translation
- Content filtering

The following topics are included in this section:

ICAP does not appear by default in the GUI. You must enable it in **System > Feature Visibility** .

The protocol

ICAP is an Application layer protocol; its specifications are set out in [RFC 3507](#). It is, in essence, a lightweight protocol for executing a "remote procedure call" on HTTP messages and is a member of the member of the TCP/IP suite of protocols.

The default TCP that is assigned to it is 1344. Its purpose is to support HTTP content adaptation by providing simple object-based content vectoring for HTTP services. ICAP is usually used to implement virus scanning and content filters in transparent HTTP proxy caches. Content adaptation refers to performing the particular value added service, or content manipulation, for an associated client request/response.

Essentially it allows an ICAP client, in this case the FortiGate firewall, to pass HTTP messages to an ICAP server like a remote procedure call for the purposes of some sort of transformation or other processing adaptation. Once the ICAP server has finished processing the content, the modified content is sent back to the client.

The messages going back and forth between the client and server are typically HTTP requests or HTTP responses. While ICAP is a request/response protocol similar in semantics and usage to HTTP/1.1 it is not HTTP nor does it run over HTTP, as such it cannot be treated as if it were HTTP. For instance, ICAP messages can not be forwarded by HTTP surrogates.

Offloading using ICAP

If you enable ICAP in a security policy, HTTP traffic intercepted by the policy is transferred to an ICAP server in the ICAP profile added to the policy. Responses from the ICAP server are returned to the FortiGate unit which forwards them to an HTTP client or server.

You can offload HTTP responses or HTTP requests (or both) to the same or different ICAP servers.

If the FortiGate unit supports HTTPS inspection, HTTPS traffic intercepted by a policy that includes an ICAP profile is also offloaded to the ICAP server in the same way as HTTP traffic.

When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

Configuring ICAP

You will need to configure an ICAP [server](#) and an ICAP [profile](#).

ICAP servers

1. Go to **Security Profiles > ICAP Servers** and click on **Create New**.
2. Enter a **Name** for the server.
3. Enter the server's **IP Address**. Depending on whether you've set the IP version to 4 or 6 will determine the format that the content of this field will be set into. In the GUI it looks like the same field with a different format but in the CLI it is actually 2 different fields named "ip-address" and ip6-address.
4. Set the **Port**; 1344 is default TCP port used for the ICAP traffic. The range can be from 1 to 65535.

Maximum Connections

This value refers to the maximum number of concurrent connections that can be made to the ICAP server. The default setting is 100. This setting can only be configured in the CLI.

The syntax is:

```
config icap server
  edit <icap_server_name>
    set max-connections <integer>
  end
```

Profiles

1. Go to **Security Profiles > ICAP** and click on **Create New**.
2. Enter a **Name** for the server.
3. Enable settings as required.
 - a. **Enable Request Processing** allows the ICAP server to process request messages. If enabled this setting will also require:
 - **Server** - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configure in the Security Profiles > ICAP > Server section.
 - **Path** - This is the path on the server to the processing content. For instance if the Windows share name was "Processes" and the directory within the share was "Content-Filter" the path would be "/Processes/Content-Filter/"
 - **On Failure** - There are 2 options: **Error** or **Bypass**.

- b. **Enable Response Processing** allows the ICAP server to process response messages. If enabled this setting will also require:
 - **Server** - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configured in the Security Profiles > ICAP > Server section.
 - **Path** - This is the path on the server to the processing component. For instance if the Windows share name was "Processes" and the directory within the share was "Content-Filter" the path would be "/Processes/Content-Filter/".
 - **On Failure** - There are 2 options. You can choose by the use of radio buttons either **Error** or **Bypass**.
- c. **Enable Streaming Media Bypass** allows streaming media to ignore offloading to the ICAP server.
- 4. Select **Apply**.

Example ICAP sequence

This example is for an ICAP server performing web URL filtering on HTTP requests

1. A user opens a web browser and sends an HTTP request to connect to a web server.
2. The FortiGate unit intercepts the HTTP request and forwards it to an ICAP server.
3. The ICAP server receives the request and determines if the request is for URL that should be blocked or allowed.
 - If the URL should be blocked the ICAP server sends a response to the FortiGate unit. The FortiGate unit returns this response to the user's web browser. This response could be a message informing the user that their request was blocked.
 - If the URL should be allowed the ICAP server sends a request to the FortiGate unit. The FortiGate unit forwards the request to the web server that the user originally attempted to connect to.
 - When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

Example ICAP scenario

Information relevant to the following example:

- The ICAP server is designed to do proprietary content filtering specific to the organization so it will have to receive the messages and send back appropriate responses.
 - The content filter is a required security precaution so if the message cannot be processed it is not allowed through.
 - Resources on both the FortiGate and the ICAP server are considerable so the maximum connections setting will be set at a double the default value to analyze the impact on performance.
 - The ICAP server's IP address is 172.16.100.55.
 - The path to the processing component is "/proprietary_code/content-filter/".
 - Streaming media is not something that the filter considers, but is allowed through the policy so processing it would be a waste of resources.
 - The ICAP profile is to be added to an existing firewall policy.
 - It is assumed that the display of the policies has already been configured to show the column "ID".
1. Enter the following to configure the ICAP server:

Go to **Security Profiles > ICAP Servers**.

Use the following values:

Name	content-filtration-server4
IP Type	IPv4
IP Address	172.16.100.55
Port	1344

Use the CLI to set the max-connections value.

```
config icap server
  edit content-filtration-server4
    set max-connections 200
  end
```

2. Enter the following to configure the ICAP profile to then apply to a security policy:

Use the following values:

Name	Prop-Content-Filtration
Enable Request Processing	enable
Server	content-filtration-server4
Path	/proprietary_code/content-filter/
On Failure	Error
Enable Response Processing	enable
Server	content-filtration-server4
Path	/proprietary_code/content-filter/
On Failure	Error
Enable Streaming Media Bypass	enable

3. Apply the ICAP profile to policy:

The purposes of this particular ICAP profile is to filter the content of the traffic coming through the firewall via policy ID#17.

- a. Go to **Policy & Objects > IPv4 Policy**.
- b. Open the existing policy ID# 17 for editing.
- c. Go to the section **Security Profiles**.
- d. Select the button next to **ICAP** so that it indicates that it's status is **ON**.
- e. Select the field with the profile name and use the drop down menu to select **Prop-Content-Filtration**.
- f. Select **OK**.

FortiClient Compliance Profiles

This section describes the FortiClient Compliance Profiles endpoint protection features and configuration.

FortiClient Compliance Profiles are used primarily to make sure connected devices are compliant with Endpoint Control and to protect against vulnerabilities. Both **Endpoint Vulnerability Scan on Client** and **System compliance** are enabled by default, while other settings are disabled by default. This allows FortiClient to work as part of a Security Fabric.

FortiClient Profiles was renamed **FortiClient Compliance Profiles** to clarify that this profile only creates "compliance rules" and cannot be used to "provision FortiClient endpoints".

You must first enable this feature. Go to System > Feature Visibility and enable Endpoint Control. This will reveal the Security Profiles > FortiClient Compliance menu item.

The following topics are included in this section:

Endpoint protection overview

Endpoint Protection enforces the use of up-to-date FortiClient Endpoint Security software on endpoints (workstation computers and mobile devices). It pushes a FortiClient profile to the FortiClient application, specifying security settings, including:

- Real-time antivirus protection - on or off
- FortiClient web category filtering based on web filters defined in a FortiGate Web Filter profile
- FortiClient Application Control (application firewall) using application sensors defined in the FortiGate Application Control profile

The FortiClient profile can also:

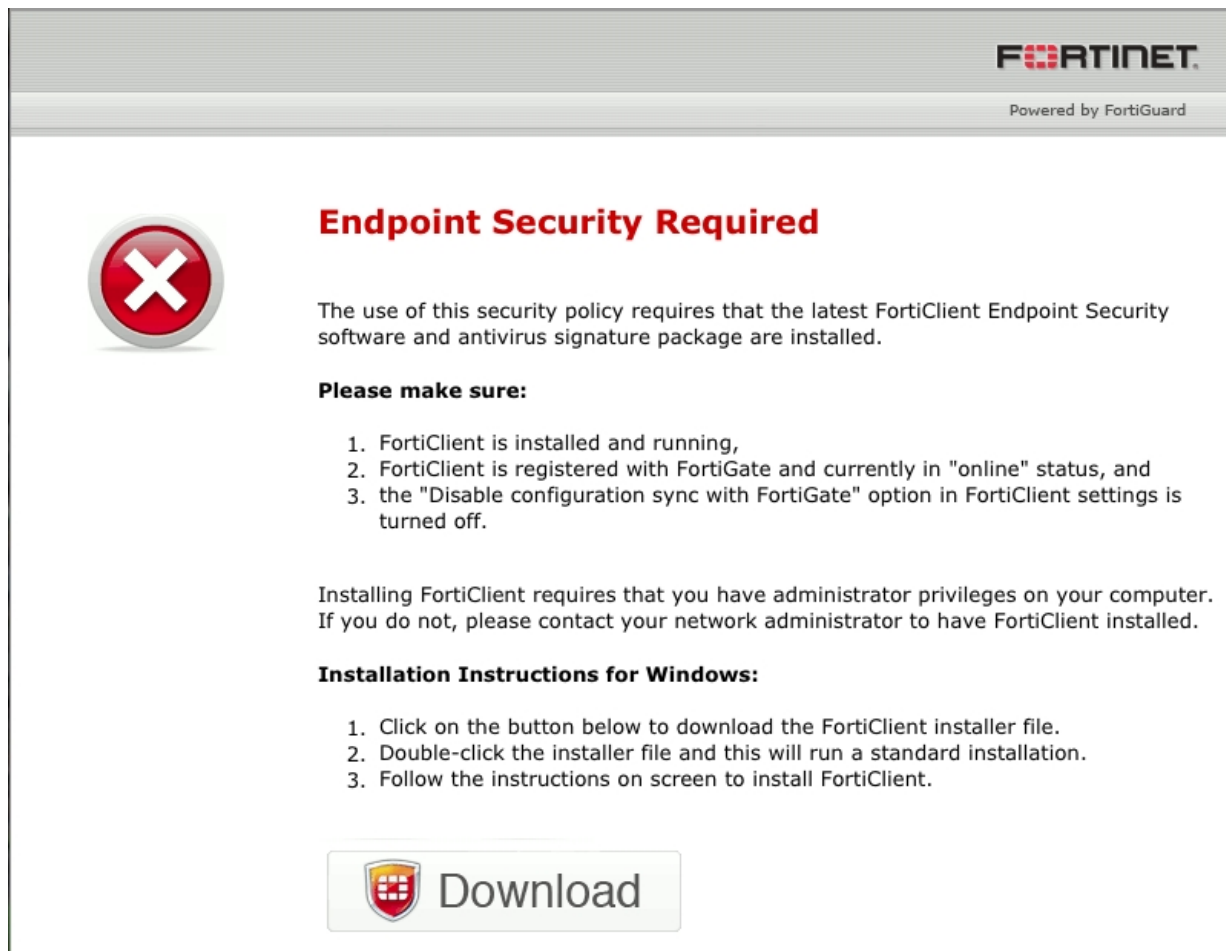

- Create VPN configurations
- Install CA certificates
- Upload logs to FortiAnalyzer or FortiManager
- Enable use of FortiManager for client software/signature update
- Enable a dashboard banner
- Enable client-based logging while on-net
- Output a mobile configuration profile (.mobileconfig file for iOS)

User experience

When using a web browser, the user of a non-compliant endpoint receives a replacement message HTML page from the FortiGate unit. The message explains that the user needs to install FortiClient Endpoint Security and provides a link to do so. The user cannot continue until the FortiClient software is installed.

For information about modifying the replacement message, see [Modifying the endpoint protection replacement messages on page 2552](#).

Default FortiClient non-compliance message for Windows

After installing FortiClient Endpoint Security, you will receive an invitation to register with the FortiGate unit. If you accept the invitation, the FortiClient profile is sent to the device's FortiClient application. Now the device is compliant and can connect to the network. FortiClient Endpoint Security registered with a FortiGate unit does not need to be separately licensed with FortiGuard.

The FortiGate unit can also register endpoints connecting over the Internet through a VPN. See [Configuring endpoint registration over a VPN on page 2548](#).

Licensing and FortiGate endpoint registration limits

To view the number of endpoints that are registered and the total that can be registered, go to **Dashboard**. Under **Licenses**, find **FortiClient**. You will see text like "4 / 10". This means that there are four registered endpoints and a total of ten are allowed.

When the registration limit is reached, the next FortiClient-compatible device will not be able to register with the FortiGate unit. A message appears in the FortiClient application. The FortiClient profile is not sent to client and the client cannot connect through the FortiGate unit.

For all FortiGate models, the maximum number of registered endpoints is ten. For all models except 20C, you can purchase an endpoint license to increase this capacity:

To add an endpoint license - GUI

1. Go to **Dashboard**.
2. In the **Licenses** widget, click on **FortiClient**, select **Enter License**.
3. Enter the license key in the window that slides in from the right, and select **OK**.

Maximum registered endpoints with endpoint license

FortiClient endpoint licenses for FortiOS 5.6.0 can be purchased in multiples of 100. There is a maximum client limit based on the FortiGate's model. FortiCare enforces the maximum limits when the customer is applying the license to a model.

If you are using the ten free licenses for FortiClient, support is provided on the Fortinet Forum (forum.fortinet.com). Phone support is only available for paid licenses.

Model(s)	Maximum Client Limit
VM00	200
FGT/FWF 30 to 90 series	200
FGT 100 to 400 series	600
FGT 500 to 900 series, VM01, VM02	2,000
FGT 1000 to 2900 series	20,000
FGT 3000 to 3600 series, VM04	50,000
FGT 3700D and above, VM08 and above	100,000

Older FortiClient SKUs will still be valid and can be applied to FortiOS 5.4 and 5.6.

Configuring endpoint protection

Endpoint Protection requires that all hosts connecting to an interface have the FortiClient Endpoint Security application installed. Make sure that all endpoints behind the interface are able to install this application. Currently, FortiClient Endpoint Security is available for Microsoft Windows (2000 and later), Apple (Mac OS X and later), and Android devices only.

By default, the FortiGuard service provides the FortiClient installer. If you prefer to host it on your own server, see [Changing the FortiClient installer download location](#), below.

To set up Endpoint Protection, complete the following:

- Create a FortiClient Profile or use the default profile. See [Creating a FortiClient profile on page 2544](#). Enable the application sensor and web category filtering profiles that you want to use.
- Configure the FortiGate unit to support endpoint registration using FortiTelemetry (under **Network > Interfaces**, allow FortiTelemetry admission control).

- Optionally, enforce FortiClient registration. See [Enforcing FortiClient registration on page 2545](#).
- Optionally, configure application sensors and web filter profiles as needed to monitor or block applications.
- Optionally, modify the **Endpoint NAC Download Portal** replacement messages (one per platform). See [Modifying the endpoint protection replacement messages on page 2552](#).

Creating a FortiClient profile

FortiClient profiles allow you to perform vulnerability scans on endpoints and make sure endpoints are running compliant versions of FortiClient. Also, security posture features cause FortiClient to apply realtime protection, AntiVirus, web filtering, and application control on endpoints.

It is possible for more than one profile to be assigned to a device type. As with security policies, clients are matched to FortiClient profiles in the order that the profiles appear in the list.

Features involving general settings have been removed from the FortiClient profile GUI in 5.4.1. Features emphasizing compliance of the endpoint devices have been added. These enhancements facilitate integration with the Security Fabric.

To create a FortiClient profile - GUI

1. If you plan to use the Application Firewall feature in the FortiClient profile, go to **Security Profiles > Application Control** to create the Application Sensors that you will need.
2. If you plan to use the Web Category Filtering, go to **Security Profiles > Web Filter** to create the Web Filter Profile that you will need.
3. Go to **Security Profiles > FortiClient Compliance**. If there is only the default FortiClient profile, it will be displayed and ready to edit. At the top right of the page you can select or create other profiles.
4. Select **Create New** or edit an existing profile.
5. In **Assign Profile To**, select the device groups, user groups, and users to which this FortiClient profile applies. ***This is not available for the default profile.***
6. Set the **Endpoint Vulnerability Scan on Client** quarantine level. Similar to FortiOS 5.4, you can set the FortiClient Profile to run the FortiClient vulnerability scanner on endpoints and you can set the vulnerability quarantine level to quarantine endpoints that don't comply. The FortiGate will quarantine a host when a vulnerability with the level of severity selected, or higher, is detected. Options are: **Critical, High, Medium, Low, and Information**.
7. **System Compliance** FortiOS 5.6 system compliance settings are similar to those in 5.4 with the addition of a non-compliance action. System compliance checking is performed by FortiClient but the non-compliance action is applied by the FortiGate:
 - select the **Minimum FortiClient version**, if necessary. The lowest supported version is 5.4.1.
 - identify which logs, if any, you will upload to FortiAnalyzer
 - set the **Non-compliance action: Block or Warning**.
8. Under **Security Posture Check**, enable the required options for your network:
 - **Realtime Protection**
 - **Third party AntiVirus on Windows** is required for Windows endpoints
 - identify which logs, if any, you will upload to FortiAnalyzer
 - select whether to enable an **Web Filter** security profile, and / or an **Application Control** sensor.
 - set the **Non-compliance action: Block or Warning**.
9. Select **OK** or **Apply**.

To create a FortiClient profile - CLI:

This example creates a profile for Windows and Mac computers.

```
config endpoint-control profile
  edit ep-profile1
    set device-groups mac windows-pc
    config forticlient-winmac-settings
      set forticlient-av enable
      set forticlient-wf enable
      set forticlient-wf-profile default
    end
  end
```

Support FortiClient for Linux

FortiClient for Linux (Ubuntu, CentOS, Red Hat, and Fedora) is also supported.

Syntax

```
config forticlient-winmac-settings
  config forticlient-operating-system
    edit <id>
      set os-type {ubuntu-linux | centos-linux | redhat-linux | fedora-linux | ...}
    next
    set forticlient-linux-ver <forticlient-version>
  end
```

Enforcing FortiClient registration

When you enable FortiTelemetry (formerly known as FortiHeartbeat) on an interface, the option to enforce FortiClient registration becomes available. Devices connecting to that interface are forced to register to the FortiGate and install FortiClient before gaining access to network services.

The following example includes editing the default FortiClient Profile to enforce real time antivirus protection and malicious website blocking.

To enforce FortiClient registration on the internal interface - GUI:

1. On the FortiGate, go to **System > Feature Visibility** and enable **Endpoint Control**.
2. Go to **Network > Interfaces** and edit the internal interface.
3. Under **Administrative Access**, enable **FortiClient Telemetry**.
4. Under **Admission Control**, enable **Enforce FortiClient Compliance Check**.
Once this is enabled, you have the option to **Exempt Sources** and/or **Exempt Destinations/Services**. If you were to exempt a source device, that device would not require FortiClient registration to access network services or the Internet.
5. Go to **Security Profiles > FortiClient Profiles**.
6. Under the **Security Posture Check**, enable **Realtime Protection, Up-to-date signatures**.

Endpoint compliance checking

Previously, as part of the Endpoint Compliance - Authorized Machine Detection feature, the administrator could specify a process name and SHA256 signature for a process, and only allow access to hosts with the specified

process/application running. The FortiGate verifies if the process name and hash is matched on the connecting host to allow access.

In FortiOS 6.0, however, the FortiGate only matches the process name, and matching the SHA256 signature is optional (since the process may be updated dynamically and the signature may not match). The administrator can specify a process name and not specify a checksum, and so only the file name will be matched. If both file name and MD5 are specified, then both fields will still be matched.

A host check table has been added to the FortiClient Profile GUI, which is similar to a policy table; the match is performed from top to bottom. At the bottom of the table, there is an implicit entry, representing everything that does not match the higher entries. This implicit entry is always available, but the administrator can change the action to either **present** or **absent** (in reference to the specified process/application).

Syntax

A new attribute `application-check-rule` determines if the entry is for checking the presence or absence of an application:

```
config endpoint-control profile
edit <name>
  config forticlient-winmac-settings
  ....
  config forticlient-running-app
  edit 1
    set app-name "MSOffice"
    set application-check-rule {present | absent}
    set process-name "word.exe"
  next
  ...
```

In addition, the `app-sha256-signature` entry is no longer mandatory, so long as the `process-name` entry is set:

```
config endpoint-control profile
edit <name>
  config forticlient-winmac-settings
  ....
  config forticlient-running-app
  edit <name>
    set app-name <name>
    set application-check-rule present
    set process-name "word.exe"
    set app-sha256-signature '' <== this field can be left empty
    set process-name2 "excel.exe"
    set app-sha256-signature2 '' <== not mandatory if process-name entry is set
    set process-name3 ''
    set app-sha256-signature3 '' <== not mandatory if process-name entry is set
    set process-name4 ''
    set app-sha256-signature4 '' <== not mandatory if process-name entry is set
  next
  ...
```

Enforcing FortiClient EMS requirements

FortiClient Compliance Profiles allow you to add up to three Enterprise Management Server (EMS) servers under **Security Profiles > FortiClient Compliance Profiles**.

This replaces the feature-related configuration (i.e AV, WF configuration) for compliance checks. Instead, if a FortiClient endpoint is managed by the defined EMS and is "in-sync" with the EMS profile then it is considered compliant.

An endpoint is considered compliant (thus allowed network access) only when the following conditions are met:

- the endpoint has FortiClient software
- the FortiClient software is managed by the authorized EMS server

Any endpoint that does not meet the above criteria (unless exempted) will be blocked from network access, regardless of FortiClient settings on that endpoint.

Syntax

```
config endpoint-control profile
  edit <name>
    config {forticlient-winmac-settings | forticlient-android-settings | forticlient-
      ios-settings}
      set forticlient-ems-compliance {enable | disable}
      set forticlient-ems-compliance-action {block | warning}
      set forticlient-ems-entries [addr1] [addr2] [addr3]
    next
  end
end

config endpoint-control settings
  set forticlient-ems-rest-api-call-timeout <milliseconds>
end
```

Changing the FortiClient installer download location

By default, FortiClient installers are downloaded from the FortiGuard network. You can also host these installers on a server for your users to download. In that case, you must configure FortiOS with this custom download location. For example, to set the download location to a customer web server with address custom.example.com, enter the following command:

```
config endpoint-control settings
  set download-location custom
  set download-custom-link "http://custom.example.com"
end
```

Storing FortiClient configuration files

Advanced FortiClient configuration files of up to 32k may be stored:

1. Enable the advanced FortiClient configuration option in the endpoint profile:

```
config endpoint-control profile
  edit "default"
    set forticlient-config-deployment enable
    set fct-advanced-cfg enable
    set fct-advanced-cfg-buffer "hello"
    set forticlient-license-timeout 1
    set netscan-discover-hosts enable
  next
end
```

2. Export the configuration from FortiClient (xml format).
3. Copy the contents of the configuration file and paste in the advanced FortiClient configuration box.

If the configure file is greater than 32k, you need to use the following CLI:

```
config endpoint-control profile
  edit <profile>
    config forticlient-winmac-settings
      config extra-buffer-entries
        edit <entry_id>
          set buffer xxxxxx
        next
      end
    end
  next
end
```

Blocking access to unsupported FortiClient endpoints

You can use the following command to deny registration of unsupported FortiClient endpoints. An unsupported FortiClient endpoint means the endpoint is running FortiClient but for some reason not all of the criteria are available to identify the endpoint, or the endpoint may be running an unsupported version of FortiClient. Information required that is not available could include the endpoint's IP address or MAC address is not visible.

```
config endpoint-control setting
  set forticlient-dereg-unsupported-client enable
end
```

Configuring the FortiClient offline grace period

Administrators can configure an offline grace period for registered and offline FortiClients so that PROBE can be processed and, as a result, endpoint compliance is not triggered.

- The grace period is allowed for a client that is compliant, registered, and offline.
- The grace period has a used status which determines if the client is before, during, or after grace period.
- Online and compliant clients will reset the grace status to unused.

Syntax

```
config endpoint-control settings
  set forticlient-offline-grace {enable | disable}
  set forticlient-offline-grace-interval <seconds>  <-- The default is 120
end
```

Configuring endpoint registration over a VPN

FortiGate units can register FortiClient-equipped endpoints over either an interface-based IPsec VPN or a tunnel-mode SSL VPN. After the user authenticates, the FortiGate unit sends the FortiClient application the IP address and port to be used for registration. If the user accepts the FortiGate invitation to register, registration proceeds and the FortiClient profile is downloaded to the client.

Users without FortiClient Endpoint Security connecting to the SSL VPN through a browser are redirected to a captive portal to download and install the FortiClient software.

Endpoint registration on an IPsec VPN

You can enable endpoint registration when you configure the FortiClient VPN or you can enable it on an existing FortiClient VPN.

To enable endpoint registration while configuring the VPN

- Enable **Allow Endpoint Registration** on the Policy & Routing page of the VPN Wizard when creating the FortiClient VPN.

This is only available when **Template Type** is set to **Remote Access** with a FortiClient **Remote Device Type**.

To enable endpoint registration on an existing VPN

1. Go to **Network > Interfaces** and edit the VPN's tunnel interface.
The tunnel is a virtual interface under the physical network interface.
2. In **Admission Control**, enable **FortiClient Telemetry**.
Optionally, you can also enable **Enforce FortiClient Telemetry for all FortiClients**. This forces endpoints to register with FortiClient before they have network access.
3. Select **OK**.

Endpoint registration on an SSL-VPN

To enable endpoint registration on the SSL-VPN

1. Go to **VPN > SSL-VPN Settings**.
2. In **Tunnel Mode Client Settings**, make sure **Allow Endpoint Registration** is enabled.
3. Select **Apply**.
4. Go to **Network > Interfaces** and edit the **ssl.root** interface.
5. In **Admission Control**, enable **FortiTelemetry**.
Optionally, you can also enable **Enforce FortiClient Telemetry for all FortiClients**. This forces endpoints to register with FortiClient before they have network access.
6. Select **OK**.

This procedure does not include all settings needed to configure a working SSL-VPN.

Synchronizing endpoint registrations

To support roaming users in a network with multiple FortiGate units, you need to configure synchronization of the endpoint registration databases between the units. The registered endpoints are then recognized on all of the FortiGate units. This is configured in the CLI. For example, to synchronize this FortiGate unit's registered endpoint database with another unit named `other1` at IP address 172.20.120.4, enter:

```
config endpoint-control forticlient-registration-sync
  edit other1
    set peer-ip 172.20.120.4
  end
```

Assigning FortiClient Profiles using Microsoft AD user groups

When FortiClient Telemetry connects to FortiGate, the user's AD domain name and group are sent to FortiGate. Administrators may configure FortiGate to assign Endpoint Profiles based on the end user's AD domain group membership.

The following steps are discussed in more detail:

- [Configuring users and groups on AD servers](#)
- [Configuring FortiAuthenticator](#)
- [Configuring FortiGate](#)
- [Connecting FortiClient Telemetry to FortiGate](#)
- [Monitoring FortiClient connections](#)

Configuring users and groups on AD servers

Create the user accounts and groups on the AD server. Groups may have any number of users. A user may belong to more than one group at the same time.

Configuring FortiAuthenticator

Configure FortiAuthenticator to use the AD server you created. See the FortiAuthenticator Administration Guide in the [Fortinet Document Library](#).

Configuring FortiGate

FortiGate

Add the FortiAuthenticator or Fortinet Single Sign-On Agent (FSSO):

1. Go to **Security Fabric > Fabric Connectors**.
2. Select **Create New** in the toolbar. The New Fabric Connector window opens.
3. Under **SSO/Identity**, select **Fortinet Single-Sign-On Agent**.
4. Enter the information required for the agent. This includes the name, primary and (optional) secondary IP addresses, and passwords. Select More FSSO agents to add up to three additional agents.
5. For **Collector Agent AD access mode**, select **Standard** or **Advanced**.
 - a. **Standard**: select Users/Groups to include as Single-Sign-On accounts.
 - b. **Advanced**: select an LDAP server in the dropdown list.
6. Select **OK** to save the agent configuration.

Create a user group:

1. Go to **User & Device > User Groups**.
2. Select **Create New** in the toolbar. The New User Group window opens.
3. In the **Type** field, select **Fortinet Single-Sign-On (FSSO)**.
4. Select members from the dropdown list.
5. Select **OK** to save the group configuration.

Configure the FortiClient profile:

1. Go to **Security Profiles > FortiClient Compliance**.
2. Select Create New in the toolbar. The New FortiClient Profile window opens.
3. Enter a profile name and optional comments.
4. In the **Assign Profile To** dropdown list select the FSSO user group(s).
5. Configure FortiClient configuration as required.
6. Select **OK** to save the new FortiClient profile.

Create any number of FortiClient profiles with different groups and different settings. The default profile will be assigned to users who connect successfully, but have no matching FortiClient profile.

Configure the firewall policy:

Configure the firewall policy. Ensure Compliant with FortiClient Profile is selected in the policy.

Connecting FortiClient Telemetry to FortiGate

The Microsoft Windows system where FortiClient is installed should join the domain of the AD server configured earlier. Users may log in with their domain username.

Following this, endpoint connections send the logged-in user's name and domain to the FortiGate. The FortiGate will assign the appropriate profiles based on the configurations.

Monitoring FortiClient connections

The following FortiOS CLI command lists information about connected clients. This includes domain-related details for the client if any.

```
diagnose endpoint record-list
Record #1:
  IP_Address = 172.172.172.111 (1)
  MAC_Address = b0:ac:6f:70:e0:a0
  Host MAC_Address = b0:ac:6f:70:e0:a0
  MAC list = b0-ac-6f-70-e0-a0;
  VDOM = root
  Registration status: Forticlient installed but not registered
  Online status: offline
  DHCP on-net status: off-net
  DHCP server: None
  FCC connection handle: 6
  FortiClient version: 5.1.29
  AVDB version: 22.137
  FortiClient app signature version: 3.0
  FortiClient vulnerability scan engine version: 1.258
  FortiClient feature version status: 0
  FortiClient UID: BE6B76C509DB4CF3A8CB942AED2064A0 (0)
  FortiClient config dirty: 1:1:1
  FortiClient KA interval dirty: 0
  FortiClient Full KA interval dirty: 0
  FortiClient server config: d9f86534f03fbed109676ee49f6cfc09::
  FortiClient config: 1
  FortiClient iOS server mconf:
```

```

FortiClient iOS mconf:
FortiClient iOS server ipsec_vpn mconf:
FortiClient iOS ipsec_vpn mconf:
Endpoint Profile: Documentation
Reg record pos: 0
Auth_AD_groups:
Auth_group:
Auth_user:
Host_Name:
OS_Version: Microsoft Windows 7 , 64-bit Service Pack 1 (build 7601)

status -- none: 0; uninstalled: 0; unregistered: 1; registered: 0; blocked: 0

```

Modifying the endpoint protection replacement messages

If the security policy has **Redirect all non-compliant/unregistered FortiClient compatible devices to a captive portal** enabled, users of non-compliant devices are redirected to a captive portal that is defined by the **Endpoint NAC Download Portal** replacement message. There are different portals for Android, iOS, Mac, Windows, Quarantine, and “other” devices.

To modify the the endpoint protection replacement messages

1. Go to **System > Replacement Messages** and select **Extended View**.
2. In the **Endpoint Control** section select the message that you want to edit.
The replacement message and its HTML code appear in a split screen in the lower half of the page.
3. Modify the text as needed and select **Save**.

Monitoring endpoints

Go to **Monitor > FortiClient Monitor** to monitor endpoints.

The **Monitor** page allows the user to view FortiClient endpoint devices grouped by interface and then sub-grouped by compliance status. Compliance status can be compliant, non-compliant, exempt, or quarantined.

Status	Enforcement Enabled	Enforcement Disabled
Compliant	List only active FortiClient endpoints.	No devices listed.
Not-compliant	List devices not-compliant with FortiClient profile, so long as they are not exempt.	No devices listed.

Status	Enforcement Enabled	Enforcement Disabled
Exempt*	List FortiClient endpoints exempt from FortiClient compliance.	List of all user devices except those quarantined by the administrator.
Quarantined	List devices quarantined by the administrator.	List devices quarantined by the administrator.

* Includes device exempt reasons as any combination of device, device category/group, and source address.

You can see the reasons for non-compliance by right-clicking on an endpoint in the list.

Proxy options

Certain inspections defined in security profiles require that the traffic be held in proxy while the inspection is carried out. When a security profile requiring the use of a proxy is enabled in a policy, the **Proxy Options** field is displayed. The Proxy Options define the parameters of how the traffic will be processed and to what level the traffic will be processed. There can be multiple security profiles of a single type. There can also be a number of unique Proxy Option profiles. As the requirements for a policy differ from one policy to the next, a different Proxy Option profile for each individual policy can be configured or one profile can be repeatedly applied.

The **Proxy Options** refer to the handling of the following protocols:

- HTTP
- SMTP
- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS

The configuration for each of these protocols is handled separately.

The use of different proxy profiles and profile options

Just like other components of the FortiGate, different Proxy Option profiles can be configured to allow for granular control of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

Proxy Options profile components

Highlighted below are certain features available in the **Proxy Options** security profile.

Log Oversized Files

This setting enables logging of the occurrence of oversized files being processed. It does not change how they are processed. It only enables the FortiGate unit to log that they were either blocked or allowed through. A common practice is to allow larger files through without antivirus processing. This allows you to get an idea of how often this happens and decide on whether or not to alter the settings relating to the treatment of oversized files.

The setting of the threshold for oversized files and emails is found on the Security Profiles > Proxy Options page under **Common Options**.

RPC over HTTP

FortiGate units with firmware version 5.4 and higher support RPC over HTTP. This protocol is used by the Microsoft Exchange Server to perform virus scanning of Microsoft Exchange Server email that uses RPC over HTTP. To enable this feature, go to **Security Profiles > Proxy Options** and enable **RPC over HTTP**.

Protocol Port Mapping

To optimize the resources of the unit, the mapping and inspection of protocols can be enabled or disabled.

Each of the protocols listed in the GUI has a commonly used default TCP port, however, the port used by the protocols can be individually modified. It can also be set to inspect any port with flowing traffic for that particular protocol. The headers of the packets indicate which protocol generated the packet.

Comfort Clients

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit begins scanning the file. During the buffering and scanning procedure, the user must wait. After the scan is completed, if no infection is found, the file is sent to the next step in the process flow. If the file is a large one this part of the process can take some time. In some cases enough time that some users may get impatient and cancel the download.

The **Comfort Clients** feature mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete. The user then knows that processing is taking place and that there hasn't been a failure in the transmission. The slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned and found to be clean of any viruses, the transfer will proceed at full speed.

If there is evidence of an infection, the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file. If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. A notification that the download has been blocked is displayed. The number of URLs in the cache is limited by the size of the cache.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Buffering the entire file allows the FortiGate unit to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Block Oversized File/Email

This feature is related to antivirus scanning. The FortiGate unit has a finite amount of resources that can be used to buffer and scan a file. If a large file such as an ISO image or video file was to be downloaded this could overwhelm or exceed the memory of the FortiGate, especially if there were other large files being downloaded at the same time. For this reason, the treatment of large files needs to be addressed.

A threshold is assigned to identify an oversized file or email. This can be set at any size from 1 MB to 10 MB. Any file or email over this threshold will not be processed by policies applying the Antivirus security profile.

It should be noted that in terms of probability that malware is more likely to be found in smaller files than in larger files. A number of administrators take this into account when they lower the default threshold so as to lessen the impact on memory if they see the FortiGate unit going into conserve mode on a regular basis.

Chunked Bypass

The HTTP section allows the enabling of **Chunked Bypass**. This refers to the mechanism in version 1.1 of HTTP that allows a web server to start sending chunks of dynamically generated output in response to a request before actually knowing the actual size of the content. Where dynamically generated content is concerned, enabling this feature means that there is a faster initial response to HTTP requests. From a security stand point, enabling this feature means that the content will not be held in the proxy as an entire file before proceeding.

Allow Fragmented Messages

The specifications of RFC 2046 allow for the breaking up of emails and sending the fragments in parallel to be rebuilt and read at the other end by the mail server. It was originally designed to increase the performance over slower connections where larger email messages were involved. It will depend on your mail configuration if this is even possible for your network but outside of Microsoft Outlook and Outlook Express, not many email clients are set up to break up messages like this. The drawback of this feature is that if malware is broken up between multiple fragments of the message the risk is run that it will not be detected by some antivirus configurations because the code may not all be present at the same time to identify.

Append Email Signature

The **Append Email Signature** feature ensures that all of the emails going out of a particular network has the appropriate signature or corporate message, for example. These appended emails do not replace existing signatures.

Examples could include things like:

- Without prior approval the email should not be forwarded.
- Please be environmentally friendly and don't print out emails
- For questions regarding the purchasing of our products please call...

It can be anything that the organization would like as long as it is in text format. The use of this feature usually works best in an environment where there is some standardization of what goes into the personal signatures of the senders so that there is no duplication or contradiction of information in the signatures.

SSL/SSH inspection

Individual deep inspection security profiles can be created depending on the requirements of the policy. Depending on the inspection profile selected, you can:

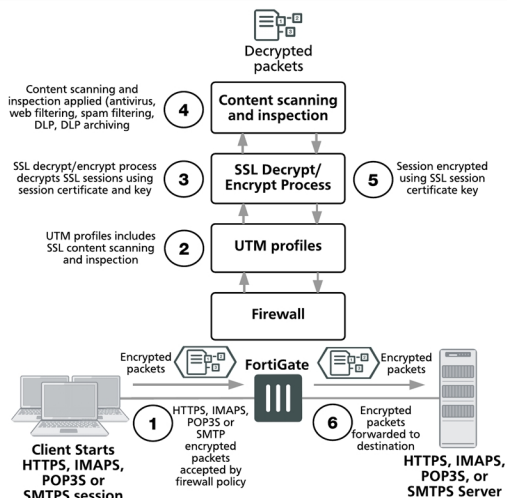

- Configure which Certificate Authority (CA) certificate will be used to decrypt the Secure Sockets Layer (SSL) encrypted traffic.
- Configure whether a specific SSL protocol will be inspected, blocked or bypassed.
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure which websites or website categories will be exempt from SSL inspection
- Identify how to treat invalid, unsupported or untrusted SSL certificates.
- Determine which inspection method will be applied to Secure Shell (SSH) / SSL traffic.

SSL inspection

Secure Sockets Layer (SSL) content scanning and inspection allows you to apply antivirus scanning, web filtering, FortiGuard Web Filtering, and email filtering to encrypted traffic. To perform SSL content scanning and inspection, the FortiGate unit does the following:

- intercepts and decrypts HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions between clients and servers (FortiGate SSL acceleration speeds up decryption)
- applies content inspection to decrypted content, including:
 - HTTPS, IMAPS, POP3S, and SMTPS Antivirus, DLP, and DLP archiving
 - HTTPS web filtering and FortiGuard web filtering
 - IMAPS, POP3S, and SMTPS email filtering
- encrypts the sessions and forwards them to their destinations.

FortiGate SSL content scanning and inspection packet flow

SSL inspection and privacy

Normally, SSL decrypted content is temporarily stored in system memory for content scanning. If Malware is found the infected content is deleted and a message is sent to the destination instead. If no Malware is found the content is re-encrypted and forwarded to its destination. Administrators are not able to access or view the decrypted content.

There are two exceptions that you should be aware of if you have privacy concerns:

- If Sandbox inspection is enabled, either with an on-premises FortiSandbox device or FortiCloud Sandbox, decrypted files can be sent to FortiSandbox or FortiSandbox cloud where they can be viewed by system administrators.
- For flow-based SSL inspection, if SSL mirroring is enabled it is possible to "mirror" or send a copy of the decrypted content to one or more FortiGate interfaces so that the content can be collected by a raw packet capture tool for archiving or analysis. This feature is only available if the inspection mode is set to flow-based.

Decryption, storage, inspection, and use decrypted content is subject to local privacy rules. Use of these features could enable malicious users with administrative access to your FortiGate to harvest sensitive information submitted using an encrypted channel.

For increased privacy of sensitive information, you can use the SSL inspection exemptions feature, described below, to exempt sensitive communication from decryption.

SSL inspection exemptions

When you are using a browser to visit SSL encrypted sites and are using a certificate that does not match the certificate of the site, you are presented with a warning message and the option of continuing with the untrusted certificate, or terminating the session. However, there are a number of applications that use SSL encrypted traffic. Some applications will not allow SSL traffic that isn't signed with a trusted certificate. These applications do not necessarily give the option to manually indicate that we trust the certificate or the site. If the option is available, the customer may choose to import needed SSL certificates into Local Certificates and configure a policy for communication for that application.

To assist in preventing loss of access to these sites while still enabling the SSL inspection of the rest of the internet traffic, a method of exempting either web categories or specific sites has been developed. To exempt a large group of sites, the **SSL/SSH Inspection** profile can be configured to exempt FortiGuard Categories. There are three preselected categories due to the high likelihood of issues with associated applications with the type of websites included in these categories.

- Finance and Banking
- Health and Wellness
- Personal Privacy

Other more specific websites can be added to the exemption list by going to **Security Profiles > SSL Inspection**, selecting the appropriate profile, and adding addresses under **Exempt from SSL Inspection**.

When you create a custom web category and tell the inspection profile to exempt that category, you may find some URLs in that category are still inspected. As a best practice, use the [Static URL filter](#) "Exempt" option instead.

Your FortiGate unit has two pre-configured SSL/SSH Inspection profiles that cannot be edited: **certificate-inspection** and **deep-inspection**. You must clone and edit the pre-configured profiles or create a new profile to exempt any additional sites or FortiGuard categories.

Allow Invalid SSL Certificates

It might seem like a straightforward decision that the allowing of invalid SSL certificates must be bad and, therefore, should not be allowed. However, there can be some reasons that applying this feature should be considered.

At a purely technical level, a properly formed certificate will encrypt the data so that it can only be read by the intended parties and not be read by anyone sniffing traffic on the network. For this reason, people will often use self-signed certificates. These self-signed certificates are free and will encrypt the data just as securely as a purchased certificate. The self-signed certificates, however, are not likely to be recognized by the CA certificate store so will be considered by any checks against that store as invalid.

On the other hand, one of the services the vendors provide is verification of identity of those that purchase their certificates. This means that if you see a valid certificate from a site that identified itself as being from “valid-company.com” that you can be reasonably sure that the site does belong to that company and not a false site masquerading as being part of that company.

You can allow invalid SSL certificates by going to **Security Profiles > SSL Inspection**, selecting the appropriate profile, and enabling **Allow Invalid SSL Certificates**.

During the SSL handshake, a number of checks are made to verify the validity of the certificate.

One source of the checks, is against a CA certificate store inside FortiOS. This is the same CA bundle used by the browser Mozilla Firefox.

Updates to the store are:

- With each new version of FortiOS
- Via internal FGD
- Possible with some builds via FTP

Details of the CA certificate store can be found at: <https://curl.haxx.se/docs/caextract.html>

The following checks are made for validity:

Validity Check	Description
Signature	One of the things being checked against the CA bundle is the certificate signature. These signatures are generated via directly signing by the CA's private key.
Expiration date	All certificates have an expiry date. The date, based on the device's clock/calendar is compared to the expiry date of the certificate.
Revoked list	Periodically, certificates are revoked. If a certificate has been revoked it is put on a list. Whenever a certificate is being verified, it is checked against this list.

Validity Check	Description
Self signed certificate	In the case of self-signed certificates, the IPS engine and proxy have different handling. IPS engine will keep and use the certificate self-signed certificate, but the public key will be replaced so that SSL inspection can take place. The proxy engine will re-sign the certificate with the untrusted CA certificate. The mechanics are similar but the net effect for the user is similar. The user will get warnings from browsers. The users can choose to remember the self-signed certificate in some browsers, but cannot do the same thing with the certificate re-signed with the untrusted CA.
Intermediate CA with a weak hash algorithm, such as MD5, SHA1	<p>Some browsers like Chrome or Firefox will give a warning because of a weak signature algorithm (visit https://sha1-intermediate.badssl.com to test).</p> <p>In the IPS Engine, in order to convey the weak intermediate CA back to client, the signature hash algorithm is downgraded in the re-signed server certificate to the weakest algorithm used in the original certificate chain.</p> <p>In the Proxy Engine - In the case of a weak signature algorithm, the Proxy engine will treat the connection as untrusted, and re-sign the server certificate with the untrusted CA. The final user experience is different. Instead of a warning like "NET::ERR_CERT_WEAK_SIGNATURE_ALGORITHM" that you would get in Chrome, you will get a warning that the certificate couldn't be verified (because of the signing CA is not trusted or imported into the user's web browser).</p>

Flow-based behaviour

In flow-based mode, a certificate will be considered as **invalid** if it has expired.

In addition, a certificate will be considered as **untrusted** if one or more of the following conditions are met:

- If the chain is broken or incomplete.
- If it is part of the CRL.
- If the CA certificate was not imported to the FortiGate, or it is not in the FortiGate CA certificate store.

Why use SSL inspection

Most of us are familiar with Hypertext Transfer Protocol Secure (HTTPS) and how it protects a variety of activities on the Internet by applying Secure Sockets Layer (SSL) encryption to the web traffic. However, there are risks associated with its use, since encrypted traffic can be used to get around your network's normal defenses.

For example, you might download a file containing a virus during an e-commerce session. Or you could receive a phishing email containing a seemingly harmless downloader file that, when launched, creates an encrypted session to a command and control (C&C) server and downloads malware onto your computer. Because the sessions in these attacks are encrypted, they might get past your network's security measures.

To protect your network from these threats, SSL inspection is the key your FortiGate uses to unlock encrypted sessions, see into encrypted packets, find threats, and block them. SSL inspection not only protects you from attacks that use HTTPS, but also from other commonly used SSL-encrypted protocols, such as SMTPS, POP3S, IMAPS, and FTPS.

Full SSL inspection

To make sure that all SSL encrypted content is inspected, you must use full SSL inspection (also known as deep inspection). When full SSL inspection is used, the FortiGate impersonates the recipient of the originating SSL session, then decrypts and inspects the content. The FortiGate then re-encrypts the content, creates a new SSL session between the FortiGate and the recipient by impersonating the sender, and sends the content to the sender.

When the FortiGate re-encrypts the content it uses a certificate stored on the FortiGate. The client must trust this certificate to avoid certificate errors. Whether or not this trust exists depends on the client, which can be the computer's OS, a browser, or some other application, which will likely maintain its own certificate repository. For more information about this, see the recipe [Preventing certificate warnings](#) on the [Fortinet Cookbook](#) site.

There are two deployment methods for full SSL inspection:

1. Multiple Clients Connecting to Multiple Servers:

- Uses a CA certificate (which can be uploaded using the **Certificates** menu).
- Typically applied to outbound policies where destinations are unknown (i.e. normal web traffic).
- Address and web category whitelists can be configured to bypass SSL inspection.

2. Protecting SSL Server

- Uses a server certificate (which can be uploaded using the **Certificates** menu) to protect a single server.
- Typically used on inbound policies to protect servers available externally through Virtual IPs
- Since this is typically deployed "outside-in" (clients on the Internet accessing server(s) on the internal side of the FortiGate), server certificates using the public FQDN of the server are often purchased from a commercial Certificate Authority and uploaded to the FortiGate. This avoids client applications generating SSL certificate errors due to certificate mismatch.

More detail is available in the Fortinet Knowledge Base. Check these technical notes:

- [How to Enable SSL inspection from the CLI and Apply it to a Policy](#)
- [How to block web-based chat on Gmail webmail using App Sensor + SSL inspection](#)

SSL certificate inspection

FortiGates also support a second type of SSL inspection, called SSL certificate inspection. When certificate inspection is used, the FortiGate only inspects the header information of the packets.

Certificate inspection is used to verify the identity of web servers and can be used to make sure that HTTPS protocol isn't used as a workaround to access sites you have blocked using web filtering.

The only security feature that can be applied using SSL certificate inspection mode is web filtering. However, since only the packet is inspected, this method does not introduce certificate errors and can be a useful alternative to full SSL inspection when web filtering is used.

Troubleshooting

The most common problem with SSL inspection is users receiving SSL errors when the CA certificate is not trusted. This is because by default the FortiGate uses a certificate that is not trusted by the client. There are two ways to fix this:

1. All users must import the FortiGate's default certificate into their client applications as a trusted certificate.
2. Configure the FortiGate to use a certificate that is already trusted by your clients. For example, a certification signed by a CA that your clients already trust.

The first method can be more labor intensive because you have to distribute a certification to all clients. This can also be an ongoing problem as new clients are added to your network. The second method is usually less work but may require paying for a CA. Both of these methods are covered in the recipe [Preventing Certificate Warnings](#).

If you choose to install the certificate on client applications, this can be done with greater ease in a Microsoft Active Directory domain environment by using Group Policy Objects to install the certificate on domain members. Check that the Group Policy has propagated to all computers by opening Internet Explorer on a workstation PC, opening **Tools > Internet Options > Content > Certificates > Trusted Root Certification Authorities**, and ensuring that the FortiGate's certificate is present.

For corporate-owned mobile devices, MDM solutions like AirWatch, MobileIron, or Fiberlink, use Simple Certificate Enrollment Protocol (SCEP) to ease certificate enrollment.

Best practices

Because all traffic needs to be decrypted, inspected, and re-encrypted, using SSL inspection can reduce overall performance of your FortiGate. To make sure you aren't using too many resources for SSL inspection, do the following:

- **Know your traffic** – Know how much traffic is expected and what percent of the traffic is encrypted. You can also limit the number of policies that allow encrypted traffic.
- **Be selective** – Use white lists or trim your policy to apply SSL inspection only where it is needed.
- **Use hardware acceleration** - FortiGate models with either the CP6 or CPU processor have an SSL/TLS protocol processor for SSL content scanning and SSL acceleration. For more information about this, see the [Hardware Acceleration handbook](#).
- **Test real-world SSL inspection performance yourself** - Use the flexibility of FortiGate's security policy to gradually deploy SSL inspection, rather than enabling it all at once.

Creating or editing an SSL/SSH Inspection profile

1. Go to **Security Profiles > SSL/SSH Inspection**. This will open to one of the existing profiles. Your FortiGate unit has two pre-configured SSL/SSH Inspection profiles that cannot be edited: certificate-inspection and deep-inspection. You must clone and edit the pre-configured profiles or create a new profile to exempt any additional sites or FortiGuard categories. The links for the actions are located in the upper right hand corner of the window.
 - To view a list of the existing profiles select the List icon (a page) at the far right.
 - To clone an existing profile, select the Clone icon (one page behind another), second from the right
 - To create a new profile, select the Create New icon ("+" symbol), third from the right.
 - To view or edit an existing profile, choose it from the dropdown menu field.
2. **Name Field:**
Give the profile an easily identifiable name that references its intent.
3. **Comments Field:**
Enter any additional information that might be needed by administrators, as a reminder of the profile's purpose and scope.
4. **SSL Inspection Options:**
 - a. Enable SSL Inspection of:

- Multiple Clients Connecting to Multiple Servers - Use this option for generic policies where the destination is unknown.
- Protecting SSL Server - Use this option when setting up a profile customized for a specific SSL server with a specific certificate.
- b. Inspection Method
The options here are:
 - SSL Certificate Inspection - only inspects the certificate, not the contents of the traffic.
 - Full SSL Inspection - inspects all of the traffic.
- c. CA Certificate
Use the drop down menu to choose which one of the installed certificates to use for the inspection of the packets or click on **Download Certificate**.
- d. Untrusted SSL Certificates
Select an action for untrusted SSL certificates.
- d. **Protocol Port Mapping** / Inspect All Ports
Enable the ability to inspect all ports by checking the box. If the feature is not enabled, specify in the field next to the listed protocols, the port through which that protocols traffic will be inspected. Traffic of that protocol going through any other port will not be inspected.

If you select **Inspect All Ports**, then only the IPS engine is used for inspection.

5. Exempt from SSL Inspection:

Use the dropdown menus in this section to specify any reputable websites, FortiGuard Web Categories, or addresses will be exempt from SSL inspection.

- Reputable Websites - Enable this option to exempt any websites identified by FortiGuard as reputable.
- Web Categories - By default the categories of Finance and Banking, Health and Wellness, and Personal Privacy, have been added as these are one that are most likely to have applications that will require a specific certificate.
- Addresses - These can be any of the Address objects that have an interface of "Any".
- Log SSL exemptions - Enable this option to log all SSL exemptions

6. SSH Inspection Options:

a. SSH Deep Scan

Toggle to disable or enable the feature

b. SSH Port

The available options are:

- **Any** - choosing this option will search all of the traffic regardless of service or TCP/IP port for packets that conform to the SSH protocol
- **Specify** - choosing this option will restrict the search for SSH protocol packets to the TCP/IP port number specified in the field. This is not as comprehensive but it is easier on the performance of the firewall.
- d. Protocol Actions
 - Exec - Block, Log or neither. Select using check boxes.
 - Port-Forward - Block, Log or neither. Select using check boxes.

- SSH-Shell - Block, Log or neither. Select using check boxes.
- X11-Filter - Block, Log or neither. Select using check boxes.

6. Common Options:

- Allow Invalid SSL Certificates
Check the box to enable the passing of traffic with invalid certificate
- Log SSL anomalies
Check the box to allow the Logging function to record traffic sessions containing invalid certificates

The **Full SSL Inspection** method is enabled by default when creating a new SSL/SSH Inspection profile. There are situations where this feature can cause issues so be sure that you would like it enabled before applying the inspection profile.

Secure white list database

You can enable a feature that gathers a list of reputable domain names that can be excluded from SSL deep inspection. This list is periodically updated and downloaded to FortiGate units through FortiGuard.

Go to **Security Profiles > SSL Inspection**, enable **Exempt from SSL Inspection**, and enable **Reputable Websites**. The reputable websites are rated by FortiGuard. Web Filtering.

CLI syntax:

```
config firewall ssl-ssh-profile
  edit deep-inspection
    set whitelist enable
  end
end
```

SSH MITM deep inspection

As vulnerabilities of OpenSSH continue to be exposed, it has become necessary to detect such attacks, which requires the ability to decrypt the SSH tunnel to check the data. This feature introduces comprehensive security controls on SSH Man-in-the-Middle (MITM) deep inspections, including:

- SSH filter profiles to control SSH tunnel types and filtering on SSH shell commands.
- SSH proxy policies to apply a proxy firewall policy with user authentication on SSH session.
- Support for SSH tunnel policy to perform access control for TCP/IP port forwarding traffic that is tunneled through the SSH proxy. IPS scanning can be applied to the tunneled traffic.
- Support for SSH trust to detect and prevent SSH MITM attacks.

Syntax

1. Add SSH related option in ssl-ssh-profile for proxy mode profile

- a. Add option to bypass or block unsupported SSH protocol (Deep scan only supports SSH 2.0)

```
config firewall ssl-ssh-profile
  edit <name>
    config ssh
      set unsupported-version {bypass | block}
    next
  end
```

```
end
```

b. Add option to enable SSH proxy policy check

```
config firewall ssl-ssh-profile
  edit <name>
    config ssh
      set ssh-policy-check {enable | disable}
      set ssh-tun-policy-check {enable | disable}
    next
  end
end
```

When SSH proxy policy check is enabled, proxy will check "SSH proxy" policy for SSH traffic and check "SSH tunnel" policy for TCP/IP port forwarding traffic.

c. Move block/log options for x11-filter/ssh-shell/exec/port-forward to SSH filter profile

2. SSH filter profile

a. Support options to block or log x11-filter/ssh-shell/exec/port-forward/sftp

```
config ssh-filter profile
  edit <name>
    set block {x11-filter | ssh-shell | exec | port-forward | sftp}
    set log {x11-filter | ssh-shell | exec | port-forward | sftp}
  next
end
```

b. Add Shell command filters

```
config ssh-filter profile
  edit <name>
    config shell-commands
      edit <id>
        set type {simple | regex}
        set pattern <cmd-string>
        set action {block | allow}
        set log {enable | disable}
        set alert {enable | disable}
        set severity {low | medium | high | critical}
      next
    end
    set default-command-log {enable | disable}
  end
```

3. Allow SSH filter profile to be set for config firewall policy when UTM is enabled.

4. Support SSH proxy policy for SSH sessions

a. Add a proxy type ssh into config firewall proxy-policy

```
config firewall proxy-policy
  edit <pol-id>
    set proxy ssh
  next
end
```

b. When user/user-group is set in SSH proxy policy, firewall authentication can be done for SSH proxy traffic. Authentication rule for SSH is added:

```

config authentication rule
  edit <name>
    set protocol ssh
  next
end

```

i. "Basic" authentication scheme:

```

config authentication scheme
  edit "ssh-active"
    set method basic
    set user-database "local" #or LDAP server
  next

```

ii. "ssh-publickey" authentication scheme:

```

config authentication scheme
  edit "ssh-pkey"
    set method ssh-publickey
    set user-database "local" #or LDAP server
    set ssh-ca "server-ca"
  next

```

User name is embedded in ssh-publickey. User group information will be retrieved if the publickey is validated by CA.

iii. Both "Basic" and "ssh-publickey" authentication scheme:

```

config authentication scheme
  edit "ssh-pkey"
    set method basic ssh-publickey
    set user-database "local" #or LDAP server
    set ssh-ca "server-ca"
  next

```

5. Support SSH tunnel policy to do access control for TCP/IP port forwarding traffic.

a. Add a proxy type ssh-tunnel into config firewall proxy-policy

```

config firewall proxy-policy
  edit <pol-id>
    set proxy ssh-tunnel
    set action {accept | deny}
  next
end

```

b. Support allow or deny and IPS sensor/app-control the traffic.

6. Support SSH trust to detect and prevent from SSH MITM attacks

a. Define trusted SSH hostkey for specific SSH server

```

config firewall ssh host-key
  edit <name>
    set status {trusted | revoked}
    set type {RSA | DSS | ECDSA}
    set nid <NID of ECDSA key>
    set ip <ip>
    set port <port>
    set hostname <name>
    set public-key <hostkey>
  next
end

```

b. Define trusted/untrusted CAs for hostkey signing. Any hostkey signed by trust CA is trusted unless the hostkey is revoked.

```
config firewall ssh local-ca
  edit <name>
    set password <passwd>
    set public-key <public key>
    set private-key <private key>
    set source {build-in | user}
  next
end
```

The system creates two build-in SSH CAs: Fortinet_SSH_CA and Fortinet_SSH_CA_Untrusted. The CAs are used to re-sign a server host key with local host-key using trusted/untrusted CA when the server host key is trusted or untrusted.

c. Define local hostkey templates for trusted re-signing. Be default, they are generated automatically.

```
config firewall ssh local-key
  edit <name>
    set password <passwd>
    set public-key <public key>
    set private-key <private key>
    set source {build-in | user}
  next
end
```

- i. The system creates different types of local host keys as default re-signing templates: Fortinet_SSH_RSA2048, Fortinet_SSH_DSA1024, Fortinet_SSH_ECDSA256, Fortinet_SSH_ECDSA384, Fortinet_SSH_ECDSA512, Fortinet_SSH_ED25519, Fortinet_SSH_RSA1024.
- ii. Admin can load their own local host keys and use them for MITM re-signing in config firewall ssh setting.

d. Per-VDOM SSH settings

```
config firewall ssh setting
  set caname <trusted-ca>
  set untrusted-caname <untrusted-ca>
  set hostkey-rsa <hostkey-rsa>
  set hostkey-dss <hostkey-dss>
  set hostkey-ecdsa256 <hostkey-ecdsa256>
  set hostkey-ecdsa384 <hostkey-ecdsa384>
  set ed25519-key <ed25519-key>
  set host-trusted-check {enable | disable}
end
```

- i. When a hostkey is trusted and signed by a CA, SSH proxy re-signs appropriate type of hostkey using trusted CA.
- ii. When a host is trusted but not signed, SSH proxy sends back appropriate type of hostkey.
- iii. When a hostkey is untrusted and signed by a CA, SSH proxy re-signs a temporary hostkey (1 hour life time) using untrusted CA.
- iv. When a host is trusted but not signed, SSH proxy sends back a temporary hostkey (one hour life time).

SSL server table for SSL offloading

An SSL server table can now be used for SSL offloading. This feature was introduced with the release of FortiOS 5.4.0.

CLI Syntax

```
config firewall ssl-ssh-profile
  edit <name>
    set use-ssl-server {enable|disable}
  next
end
```

Custom Application & IPS Signatures

Creating a custom IPS signature

The FortiGate predefined signatures cover common attacks. If you use an unusual or specialized application or an uncommon platform, add custom signatures based on the security alerts released by the application and platform vendors.

You can add or edit custom signatures using the GUI or the CLI.

To create a custom signature

1. Go to **Security Profiles > Intrusion Prevention**.
2. Select **[View IPS Signatures]**
3. Select **Create New** to add a new custom signature.
4. Enter a **Name** for the custom signature.
5. Enter the **Signature**. For information about completing this field, see [Custom signature syntax](#) and [Custom signature keywords](#).
6. Select **OK**.

Custom signature syntax

All custom signatures follow a particular syntax. Each begins with a header and is followed by one or more keywords. A custom signature definition is limited to a maximum length of 512 characters. A definition can be a single line or span multiple lines connected by a backslash (\) at the end of each line.

A custom signature definition begins with a header, followed by a set of keyword/value pairs enclosed by parenthesis [()]. The keyword and value pairs are separated by a semi colon (;) and consist of a keyword and a value separated by a space. The basic format of a definition is HEADER (KEYWORD VALUE;)

You can use as many keyword/value pairs as required within the 512 character limit. To configure a custom signature, go to **Security Profiles > Intrusion Prevention**, select **View IPS Signatures**, select **Create New**, and enter the data directly into the **Signature** field, following the guidance in the next topics.

The table below shows the valid characters and basic structure. For details about each keyword and its associated values, see [Custom signature keywords](#).

Valid syntax for custom signature fields

Field	Valid Characters	Usage
HEADER	F-SBID	The header for an attack definition signature. Each custom signature must begin with this header.

Field	Valid Characters	Usage
KEYWORD	<p>Each keyword must start with a pair of dashes (--), and consist of a string of 1 to 19 characters.</p> <p>Normally, keywords are an English word or English words connected by an underscore (_). Keywords are case insensitive.</p>	The keyword is used to identify a parameter.
VALUE	<p>Double quotes (") must be used around the value if it contains a space and/or a semicolon (;).</p> <p>If the value is NULL, the space between the KEYWORD and VALUE can be omitted.</p> <p>Values are case sensitive.</p> <p>Note: If double quotes are used for quoting the value, the double quotes are not considered as part of the value string.</p>	The value is set specifically for a parameter identified by a keyword.

Custom signature keywords

- information
- session
- content
- IP header
- TCP header
- UDP header
- ICMP
- other

Information keywords

attack_id

Syntax: --attack_id <id_int>;

Description:

Use this optional value to identify the signature. It cannot be the same value as any other custom rules. If an attack ID is not specified, the FortiGate automatically assigns an attack ID to the signature. If you are using VDOMs, custom signatures appear only in the VDOM in which you create them. You can use the same attack ID for signatures in different VDOMs.

An attack ID you assign must be between 1000 and 9999.

Example: --attack_id 1234;

name

Syntax: `--name <name_str>;`

Description:

Enter the name of the rule. A rule name must be unique. If you are using VDOMs, custom signatures appear only in the VDOM in which you create them. You can use the same rule name for signatures in different VDOMs. The name you assign must be a string greater than 0 and less than 64 characters in length.

Example: `--name "Buffer_Overflow";`

Session keywords

flow

Syntax: `--flow {from_client[,reversed] | from_server[,reversed] | bi_direction};`

Description:

Specify the traffic direction and state to be inspected. They can be used for all IP traffic.

Example: `--src_port 41523; --flow bi_direction;`

The signature checks traffic to and from port 41523.

If you enable “quarantine attacker”, the optional reversed keyword allows you to change the side of the connection to be quarantined when the signature is detected.

For example, a custom signature written to detect a brute-force log in attack is triggered when “Login Failed” is detected from_server more than 10 times in 5 seconds. If the attacker is quarantined, it is the server that is quarantined in this instance. Adding reversed corrects this problem and quarantines the actual attacker.

Previous FortiOS versions used to_client and to_server values. These are now deprecated, but still function for backwards compatibility.

service

Syntax: `--service {HTTP | TELNET | FTP | DNS | SMTP | POP3 | IMAP | SNMP | RADIUS | LDAP | MSSQL | RPC | SIP | H323 | NBSS | DCERPC | SSH | SSL};`

Description:

Specify the protocol type to be inspected. This keyword allows you to specify the traffic type by protocol rather than by port. If the decoder has the capability to identify the protocol on any port, the signature can be used to detect the attack no matter what port the service is running on. Currently, HTTP, SIP, SSL, and SSH protocols can be identified on any port based on the content.

app_cat

Syntax: `--app_cat <category_int>;`

Description:

Specify the category of the application signature. Signatures with this keyword are considered as application rules. These signatures will appear under Application Control instead of IPS configuration. To display a complete list of application signature categories, enter the following CLI commands:

```
config application list
edit default
config entries
edit 1
set category ?
```

weight

Syntax: `--weight <weight_int>;`

Description:

Specify the weight to be assigned to the signature. This keyword allows a signature with the higher weight to have priority over a signature with a lower weight. This is useful to prioritize between custom and stock signatures and also between different custom signatures.

The weight must be between 0 and 255. Most of the signatures in the Application Control signature database have weights of 10; botnet signatures are set to 250. A range of 20 to 50 is recommended for custom signatures.

Content keywords

byte_extract

Syntax: `byte_extract:<bytes_to_extract>, <offset>, <name> \ [, relative][, multiplier <multiplier value>][, <endian>]\ [, string][, hex][, dec][, oct][, align <align value>][, dce];`

Description:

Use the `byte_extract` option to write rules against length-encoded protocols. This reads some of the bytes from the packet payload and saves it to a variable.

byte_jump

Syntax: `--byte_jump <bytes_to_convert>, <offset>[, multiplier][, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct] [, align];`

Description:

Use the `byte_jump` option to extract a number of bytes from a packet, convert them to their numeric representation, and jump the match reference up that many bytes (for further pattern matching or byte testing). This keyword allows relative pattern matches to take into account numerical values found in network data. The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to examine from the packet.
- `<offset>`: The number of bytes into the payload to start processing.
- `[multiplier]`: multiplier is optional. It must be a numerical value when present. The converted value multiplied by the number is the result to be skipped.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).

- `little`: Process the data as little endian.
- `string`: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.
- `align`: Round up the number of converted bytes to the next 32-bit boundary.

byte_test

Syntax: `--byte_test <bytes_to_convert>, <operator>, <value>, <offset> [multiplier] [, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct];`

Description:

Use the `byte_test` keyword to compare a byte field against a specific value (with operator). This keyword is capable of testing binary values or converting representative byte strings to their binary equivalent and testing them. The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to compare.
- `<operator>`: The operation to perform when comparing the value (`<`, `>`, `=`, `!`, `&`).
- `<value>`: The value to compare the converted value against.
- `<offset>`: The number of bytes into the payload to start processing.
- `[multiplier]`: multiplier is optional. It must be a numerical value when present. The converted value multiplied by the number is the result to be skipped.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).
- `little`: Process the data as little endian.
- `string`: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.

depth

Syntax: `--depth <depth_int>;`

Description:

Use the `depth` keyword to search for the contents within the specified number of bytes after the starting point defined by the `offset` keyword. If no offset is specified, the offset is assumed to be equal to 0.

If the value of the `depth` keyword is smaller than the length of the value of the `content` keyword, this signature will never be matched.

The depth must be between 0 and 65535.

distance

Syntax: `--distance <dist_int>;`

Description:

Use the distance keyword to search for the contents within the specified number of bytes relative to the end of the previously matched contents. If the within keyword is not specified, continue looking for a match until the end of the payload.

The distance must be between 0 and 65535.

content

Syntax: `--content [!] "<content_str>";`

Description:

Deprecated, see pattern and context keywords. Use the content keyword to search for the content string in the packet payload. The content string must be enclosed in double quotes.

To have the FortiGate search for a packet that does not contain the specified context string, add an exclamation mark (!) before the content string.

Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character.

The double quote ("), pipe sign(|) and colon(:) characters must be escaped using a back slash if specified in a content string.

If the value of the content keyword is greater than the length of the value of the depth keyword, this signature will never be matched.

context

Syntax: `--context {uri | header | body | host};`

Description:

Specify the protocol field to look for the pattern. If context is not specified for a pattern, the FortiGate unit searches for the pattern anywhere in the packet buffer. The available context variables are:

- **uri:** Search for the pattern in the HTTP URI line.
- **header:** Search for the pattern in HTTP header lines or SMTP/POP3/SMTP control messages.
- **body:** Search for the pattern in HTTP body or SMTP/POP3/SMTP email body.
- **host:** Search for the pattern in HTTP HOST line.

no_case

Syntax: `--no_case;`

Description:

Use the no-case keyword to force the FortiGate unit to perform a case-insensitive pattern match.

offset

Syntax: `--offset <offset_int>;`

Description:

Use the offset keyword to look for the contents after the specified number of bytes into the payload. The specified number of bytes is an absolute value in the payload. Follow the offset keyword with the depth

keyword to stop looking for a match after a specified number of bytes. If no depth is specified, the FortiGate unit continues looking for a match until the end of the payload.

The offset must be between 0 and 65535.

pattern

Syntax: `--pattern [!]"<pattern_str>"`;

Description:

The FortiGate unit will search for the specified pattern. A pattern keyword normally is followed by a context keyword to define where to look for the pattern in the packet. If a context keyword is not present, the FortiGate unit looks for the pattern anywhere in the packet buffer. To have the FortiGate search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI.

Example: `--pattern "/level/" --pattern "|E8 D9FF FFFF|/bin/sh" --pattern
!"|20|RTSP/"`

pcre

Syntax: `--pcre [!]"<regex>/[ismxAEGRUB]"`;

Description:

Similarly to the pattern keyword, use the pcre keyword to specify a pattern using Perl-compatible regular expressions (PCRE). A pcre keyword can be followed by a context keyword to define where to look for the pattern in the packet. If no context keyword is present, the FortiGate unit looks for the pattern anywhere in the packet buffer.

For more information about PCRE syntax, go to <http://www.pcre.org>.

The switches include:

- **i:** Case insensitive.
- **s:** Include newlines in the dot metacharacter.
- **m:** By default, the string is treated as one big line of characters. **^** and **\$** match at the beginning and ending of the string. When **m** is set, **^** and **\$** match immediately following or immediately before any newline in the buffer, as well as the very start and very end of the buffer.
- **x:** White space data characters in the pattern are ignored except when escaped or inside a character class.
- **A:** The pattern must match only at the start of the buffer (same as **^**).
- **E:** Set **\$** to match only at the end of the subject string. Without **E**, **\$** also matches immediately before the final character if it is a newline (but not before any other newlines).
- **G:** Invert the "greediness" of the quantifiers so that they are not greedy by default, but become greedy if followed by **?**.
- **R:** Match relative to the end of the last pattern match. (Similar to `distance:0`).
- **U:** Deprecated, see the context keyword. Match the decoded URI buffers.

uri

Syntax: `--uri [!]"<uri_str>"`;

Description:

Deprecated, see pattern and context keywords. Use the uri keyword to search for the URI in the packet payload. The URI must be enclosed in double quotes ("). To have the FortiGate unit search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI. Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character. The double quote ("), pipe sign (|) and colon (:) characters must be escaped using a back slash (\) if specified in a URI string.

within

Syntax: `--within <within_int>;`

Description:

Use this together with the distance keyword to search for the contents within the specified number of bytes of the payload.

The within value must be between 0 and 65535.

IP header keywords

dst_addr

Syntax: `--dst_addr [!]<ipv4>;`

Description:

Use the dst_addr keyword to search for the destination IP address. To have the FortiGate search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

Example: `dst_addr [172.20.0.0/16, 10.1.0.0/16, 192.168.0.0/16]`

ip_dscp

Syntax: `--ip_dscp`

Description:

Use the ip_dscp keyword to check the IP DSCP field for the specified value.

ip_id

Syntax: `--ip_id <field_int>;`

Description:

Check the IP ID field for the specified value.

ip_option

Syntax: `--ip_option {rr | eol | nop | ts | sec | lsrr | ssrr | satid | any};`

Description:

Use the ip_option keyword to check various IP option settings.

The available options include:

- `rr`: Check if IP RR (record route) option is present.
- `eol`: Check if IP EOL (end of list) option is present.
- `nop`: Check if IP NOP (no op) option is present.
- `ts`: Check if IP TS (time stamp) option is present.
- `sec`: Check if IP SEC (IP security) option is present.
- `lsrr`: Check if IP LSRR (loose source routing) option is present.
- `ssrr`: Check if IP SSRR (strict source routing) option is present.
- `satid`: Check if IP SATID (stream identifier) option is present.
- `any`: Check if IP any option is present.

`ip_tos`

Syntax: `--ip_tos <field_int>;`

Description:

Check the IP TOS field for the specified value.

`ip_ttl`

Syntax: `--ip_ttl [< | >] <ttl_int>;`

Description:

Check the IP time-to-live value against the specified value. Optionally, you can check for an IP time-to-live greater-than (>) or less-than (<) the specified value with the appropriate symbol.

`protocol`

Syntax: `--protocol {<protocol_int> | tcp | udp | icmp};`

Description:

Check the IP protocol header.

Example: `--protocol tcp;`

`src_addr`

Syntax: `--src_addr [!]<ipv4>;`

Description:

Use the `src_addr` keyword to search for the source IP address. To have the FortiGate unit search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

Example: `src_addr 192.168.13.0/24`

TCP header keywords

`ack`

Syntax: `--ack <ack_int>;`

Description:

Check for the specified TCP acknowledge number.

dst_port

Syntax: `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

Description:

Use the `dst_port` keyword to specify the destination port number.

You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

seq

Syntax: `--seq [operator,]<number>[,relative];`

Description:

Check for the specified TCP sequence number.

- `operator` includes `=,<,>,!`.
- `relative` indicates it's relative to the initial sequence number of the TCP session.

src_port

Syntax: `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

Description:

Use the `src_port` keyword to specify the source port number. You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

tcp_flags

Syntax: `--tcp_flags <SAFRUP120>[!|*|+] [,<SAFRUP120>];`

Description:

Specify the TCP flags to match in a packet.

- S: Match the SYN flag.
- A: Match the ACK flag.
- F: Match the FIN flag.
- R: Match the RST flag.

- U: Match the URG flag.
- P: Match the PSH flag.
- 1: Match Reserved bit 1.
- 2: Match Reserved bit 2.
- 0: Match No TCP flags set.
- !: Match if the specified bits are not set.
- *: Match if any of the specified bits are set.
- +: Match on the specified bits, plus any others.

The first part of the value (<SAFRUP120>) defines the bits that must be present for a successful match.

Example:

`--tcp_flags AP` only matches the case where both A and P bits are set.

The second part ([, <SAFRUP120>]) is optional, and defines the additional bits that can be present for a match.

For example `tcp_flags S,12` matches the following combinations of flags: S, S and 1, S and 2, S and 1 and 2. The modifiers !, * and + cannot be used in the second part.

window_size

Syntax: `--window_size [!]<window_int>;`

Description:

Check for the specified TCP window size. You can specify the window size as a hexadecimal or decimal integer. A hexadecimal value must be preceded by 0x. To have the FortiGate search for the absence of the specified window size, add an exclamation mark (!) before the window size.

UDP header keywords

dst_port

Syntax: `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

Description:

Specify the destination port number. You can specify a single port or port range:

- <port_int> is a single port.
- :<port_int> includes the specified port and all lower numbered ports.
- <port_int>: includes the specified port and all higher numbered ports.
- <port_int>:<port_int> includes the two specified ports and all ports in between.

src_port

Syntax: `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>;}`

Description:

Specify the destination port number. You can specify a single port or port range:

- <port_int> is a single port.
- :<port_int> includes the specified port and all lower numbered ports.
- <port_int>: includes the specified port and all higher numbered ports.
- <port_int>:<port_int> includes the two specified ports and all ports in between.

ICMP keywords

icmp_code

Syntax: --icmp_code <code_int>;

Description:

Specify the ICMP code to match.

icmp_id

Syntax: --icmp_id <id_int>;

Description:

Check for the specified ICMP ID value.

icmp_seq

Syntax: --icmp_seq <seq_int>;

Description:

Check for the specified ICMP sequence value.

icmp_type

Syntax: --icmp_type <type_int>;

Description:

Specify the ICMP type to match.

Other keywords

data_size

Syntax: --data_size {<size_int> | <<size_int> | >>size_int};

Description:

Test the packet payload size. With data_size specified, packet reassembly is turned off automatically. So a signature with data_size and only_stream values set is wrong.

- <size_int> is a particular packet size.
- <<size_int> is a packet smaller than the specified size.
- >>size_int> is a packet larger than the specified size.

Examples:

- `--data_size 300;`
- `--data_size <300;`
- `--data_size >300;`

data_at

Syntax: `--data_at <offset_int>[, relative];`

Description:

Verify that the payload has data at a specified offset, optionally looking for data relative to the end of the previous content match.

dump-all-html

Syntax: `--dump-all-html`

Description:

Dump all HTML files for benchmarking via iSniff. When there is no file type specified, all HTML files are dumped.

rate

Syntax: `--rate <matches_int>,<time_int>;`

Description:

Instead of generating log entries every time the signature is detected, use this keyword to generate a log entry only if the signature is detected a specified number of times within a specified time period.

- `<matches_int>` is the number of times a signature must be detected.
- `<time_int>` is the length of time in which the signature must be detected, in seconds.

For example, if a custom signature detects a pattern, a log entry will be created every time the signature is detected. If `--rate 100,10;` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. Use this command with `--track` to further limit log entries to when the specified number of detections occur within a certain time period involving the same source or destination address rather than all addresses.

rpc_num

Syntax: `--rpc_num <app_int>[, <ver_int> | *][, <proc_int> | *];`

Description:

Check for RPC application, version, and procedure numbers in SUNRPC CALL requests. The * wild card can be used for version and procedure numbers.

same_ip

Syntax: `--same_ip;`

Description:

Check that the source and the destination have the same IP addresses.

track

Syntax: `--track {SRC_IP | DST_IP | DHCP_CLIENT | DNS_DOMAIN}[,block_int];`

Description:

When used with `--rate`, this keyword narrows the custom signature rate totals to individual addresses.

- `SRC_IP`: tracks the packet's source IP.
- `DST_IP`: tracks the packet's destination IP.
- `DHCP_CLIENT`: tracks the DHCP client's MAC address.
- `DNS_DOMAIN`: counts the number of any specific domain name.
- `block_int` has the FortiGate unit block connections for the specified number of seconds, from the client or to the server, depending on which is specified.

For example, if `--rate 100,10` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. The FortiGate unit maintains a single total, regardless of source and destination address.

If the same custom signature also includes `--track client`; matches are totaled separately for each source address. A log entry is added when the signature is detected 100 times in 10 seconds within traffic from the same source address.

The `--track` keyword can also be used without `--rate`. If an integer is specified, the client or server will be blocked for the specified number of seconds every time the signature is detected.

Creating a custom signature to block access to example.com

In this first example, you will create a custom signature to block access to the example.com URL.

This example describes the use of the custom signature syntax to block access to a URL. To create the custom signature entry in the FortiGate's GUI, see [Custom Application & IPS Signatures](#).

1. Enter the custom signature basic format.

All custom signatures have a header and at least one keyword/value pair. The header is always the same:

```
F-SBID( )
```

The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

Every custom signature requires a name, so it is a good practice to assign a name before adding any other keywords. Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

```
F-SBID( --name "Block.example.com"; )
```

The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

3. Add a signature pattern

Use the `--pattern` keyword to specify what the FortiGate unit will search for:

```
F-SBID( --name "Block.example.com"; --pattern "example.com"; )
```

The signature will now detect the example.com URL appearing in network traffic. The custom

signature should only detect the URL in HTTP traffic, however. Any other traffic with the URL should be allowed to pass. For example, an email message to or from example.com should not be stopped.

4. Specify the service

Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

```
F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; )
```

The FortiGate unit will limit its search for the pattern to the HTTP protocol. Even though the HTTP protocol uses only TCP traffic, the FortiGate will search for HTTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

5. Specify the traffic type.

Use the `--protocol tcp` keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

```
F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --
protocol tcp; )
```

The FortiGate unit will limit its search for the pattern to TCP traffic and ignore UDP and ICMP network traffic.

6. Ignore case sensitivity

By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

Use the `--no_case` keyword to make the pattern matching case insensitive.

```
F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --
protocol tcp; --no_case; )
```

Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

7. Limit pattern scans to only traffic sent from the client

The `--flow` command can be used to further limit the network traffic being scanned to only that sent by the client or by the server.

```
F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --
protocol tcp; --no_case; --flow from_client; )
```

Web servers do not contact clients until clients first open a communication session. Therefore, using the `--flow from_client` command will force the FortiGate to ignore all traffic from the server. Since the majority of HTTP traffic flows from the server to the client, this will save considerable system resources and still maintain protection.

8. Specify the context

When the client browser tries to contact example.com, a DNS is first consulted to get the example.com server IP address. The IP address is then specified in the URL field of the HTTP communication. The domain name will still appear in the host field, so this custom signature will not function without the `--context host` keyword/value pair.

```
F-SBID( --name "Block.example.com"; --pattern "example.com"; --service HTTP; --no_
case; --flow from_client; --context host; )
```

Creating a custom signature to block the SMTP “vrfy” command

The SMTP “vrfy” command can be used to verify the existence of a single email address or to list all of the valid email accounts on an email server. A spammer could potentially use this command to obtain a list of all valid email users and direct spam to their inboxes.

In this example, you will create a custom signature to block the use of the vrfy command. Since the custom signature blocks the vrfy command from coming through the FortiGate unit, the administrator can still use the command on the internal network.

This example describes the use of the custom signature syntax to block the vrfy command. To create the custom signature entry in the FortiGate's GUI, see [Custom Application & IPS Signatures](#).

1. Enter the custom signature basic format

All custom signatures have a header and at least one keyword/value pair. The header is always the same:

```
F-SBID( )
```

The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

Every custom signature requires a name, so it is a good practice to assign a name before you add any other keywords.

Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

```
F-SBID( --name "Block.SMTP.VRFY.CMD"; )
```

The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

3. Add a signature pattern

Use the `--pattern` keyword to specify what the FortiGate unit will search for:

```
F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; )
```

The signature will now detect the vrfy command appearing in network traffic. The custom signature should only detect the command in SMTP traffic, however. Any other traffic with the pattern should be allowed to pass. For example, an email message discussing the vrfy command should not be stopped.

4. Specify the service.

Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

```
F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; )
```

The FortiGate unit will limit its search for the pattern to the SMTP protocol.

Even though the SMTP protocol uses only TCP traffic, the FortiGate will search for SMTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

5. Specify the traffic type.

Use the `--protocol tcp` keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

```
F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --
        protocol tcp; )
```

The FortiGate unit will limit its search for the pattern to TCP traffic and ignore the pattern in UDP and ICMP network traffic.

6. Ignore case sensitivity.

By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

Use the `--no_case` keyword to make the pattern matching case insensitive.

```
F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --no_case; )
```

Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

7. Specify the context.

The `SMTP vrfy` command will appear in the SMTP header. The `--context host keyword/value` pair allows you to limit the pattern search to only the header.

```
F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; --service SMTP; --no_case; -
        -context header; )
```

Creating a custom signature to block files according to the file's hash value

In this example, you will create a custom signature that allows you to specify a hash value (or checksum) of a file that you want to block. To block multiple files you can create a custom signature for each file with that file's hash value in it and then add all of the custom signatures to an IPS sensor and set the action to block for each one. When IPS encounters a file with a matching hash value the file is blocked.

This example uses a CRC32 checksum of the file as the hash value of the file to be blocked. You can use any utility that supports CRC32 checksums to generate the hash value.

1. Enter the custom signature basic format.

All custom signatures have a header and at least one keyword/value pair. The header is always the same:

```
F-SBID( )
```

The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

Every custom signature requires a name, so it is a good practice to assign a name before adding any other keywords. Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

```
F-SBID( --name "File.Hash.Example"; )
```

The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic.

3. Specify the traffic type.

Use the `--protocol tcp` keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.

```
F-SBID( --name "File.Hash.Example"; --protocol tcp; )
```

The FortiGate unit will limit its search for the pattern to TCP traffic and ignore UDP and ICMP network traffic.

4. Add the CRC32 hash value.

Use the `--crc32` keyword. This indicates that the value that follows is a hexadecimal number that represents the CRC32 checksum of the file. The `--crc32` keyword also requires that you include the file length. The syntax is `--crc32 <checksum>,<file-length>;`. The following example shows the syntax for a file with checksum 51480492 and file length 822.

```
F-SBID( --name "File.Hash.Example"; --protocol tcp; --crc32 51480492,822; )
```

Other security profiles considerations

The following topics are included in this section:

- [Security profiles and Virtual Domains \(VDOMs\)](#)
- [Conserve mode](#)
- [Using wildcards and Perl regular expressions](#)
- [CPU allocation and tuning commands to survive reboot](#)

Global security profiles across Virtual domains (VDOMs)

Previously, if you enabled virtual domains (VDOMs) on your FortiGate unit, any Security Profiles configuration was limited to the VDOM in which you configured it.

Now Security Profiles can be configured globally across multiple VDOMs. In many VDOM environments, some or all profiles may be commonly-shared, for example an MSSP with "parental controls" configured will most likely have the same Web Filtering and Application Control profiles per VDOM.

Global profiles are configured under **Global > Security Profiles** in the GUI or under the following `config global` commands in the CLI:

- `antivirus profile`
- `application list`
- `dlp sensor`
- `ips sensor`
- `webfilter profile`

The name for any global profile must start with "g-" for identification. Global profiles are available as read-only for VDOM-level administrators and can only be edited or deleted from within the global settings.

Each security feature has at least one default global profile, available for all VDOMs.

Both Global security profile configuration and the various databases used by Security Profiles features are shared. The FortiGuard antivirus and IPS databases and updates to the databases are shared. The FortiGuard web filter and spam filter features access the FortiGuard distribution network and read the same information when checking email for spam and web site categories and classification.

Conserve mode

FortiGate units perform all Security Profiles processing in physical RAM. Since each model has a limited amount of memory, conserve mode is activated when the remaining free memory is nearly exhausted or the AV proxy has reached the maximum number of sessions it can service. While conserve mode is active, the AV proxy does not accept new sessions.

A warning will appear in the top bar of the FortiGate, regardless of which page in the FortiGate GUI you are on.

The AV proxy

Most content inspection the FortiGate unit performs requires that the files, email messages, URLs, and web pages be buffered and examined as a whole. The AV proxy performs this function, and because it may be buffering many files at the same time, it uses a significant amount of memory. Conserve mode is designed to

prevent all the component features of the FortiGate unit from trying to use more memory than it has. Because the AV proxy uses so much memory, conserve mode effectively disables it in most circumstances. As a result, the content inspection features that use the AV proxy are also disabled in conserve mode.

All of the Security Profiles features use the AV proxy with the exception of IPS, application control, DoS as well as flow-based antivirus, DLP, and web filter scanning. These features continue to operate normally when the FortiGate unit enters conserve mode.

Entering and exiting conserve mode

A FortiGate unit will enter conserve mode because it is nearly out of physical memory, or because the AV proxy has reached the maximum number of sessions it can service. The memory threshold that triggers conserve mode varies by model, but it is about 20% free memory. When memory use rises to the point where less than 20% of the physical memory is free, the FortiGate unit enters conserve mode.

The FortiGate unit will leave conserve mode only when the available physical memory exceeds about 30%. When exiting conserve mode, all new sessions configured to be scanned with features requiring the AV proxy will be scanned as normal, with the exception of a unit configured with the one-shot option.

Conserve mode effects

What happens when the FortiGate unit enters conserve mode depends on how you have `av-failopen` configured. There are four options:

off

The off setting forces the FortiGate unit to stop all traffic that is configured for content inspection by Security Profiles features that use the AV proxy. New sessions are not allowed but current sessions continue to be processed normally unless they request more memory. Sessions requesting more memory are terminated.

For example, if a security policy is configured to use antivirus scanning, the traffic it permits is blocked while in conserve mode. A policy with IPS scanning enabled continues as normal. A policy with both IPS and antivirus scanning is blocked because antivirus scanning requires the AV proxy.

Use the off setting when security is more important than a loss of access while the problem is rectified.

pass

The pass setting allows traffic to bypass the AV proxy and continue to its destination. Since the traffic is bypassing the proxy, no Security Profiles scanning that requires the AV proxy is performed. Security Profiles scanning that does not require the AV proxy continues normally.

Use the pass setting when access is more important than security while the problem is rectified.

Pass is the default setting.

one-shot

The one-shot setting is similar to pass in that traffic is allowed when conserve mode is active. The difference is that a system configured for one-shot will force new sessions to bypass the AV proxy even after it leaves conserve mode. The FortiGate unit resumes use of the AV proxy only when the `av-failopen` setting is changed or the unit is restarted.

idledrop

The idledrop setting will recover memory and session space by terminating all the sessions associated with the host that has the most sessions open. The FortiGate may force this session termination a number of times, until enough memory is available to allow it to leave conserve mode.

The idledrop setting is primarily designed for situations in which malware may continue to open sessions until the AV proxy cannot accept more new sessions, triggering conserve mode. If your FortiGate unit is operating near capacity, this setting could cause the termination of valid sessions. Use this option with caution.

Configuring the av-failopen command

You can configure the av-failopen command using the CLI.

```
config system global
    set av-failopen {off | pass | one-shot | idledrop}
end
```

The default setting is pass.

Using wildcards and Perl regular expressions

Many Security Profiles feature list entries can include wildcards or Perl regular expressions.

For more information about using Perl regular expressions, see <http://perldoc.perl.org/perlretut.html>.

Regular expression vs. wildcard match pattern

A wildcard character is a special character that represents one or more other characters. The most commonly used wildcard characters are the asterisk (*), which typically represents zero or more characters in a string of characters, and the question mark (?), which typically represents any one character.

In Perl regular expressions, the '.' character refers to any single character. It is similar to the '?' character in wildcard match pattern. As a result:

- example.com not only matches example.com but also examplea.com, exampleb.com, examplec.com, and so on.

To add a question mark (?) character to a regular expression from the FortiGate CLI, enter Ctrl+V followed by ?. To add a single backslash character (\) to a regular expression from the CLI you must add precede it with another backslash character. For example, `example\\.com`.

To match a special character such as '.' and '*' use the escape character '\\'. For example:

- To match example.com, the regular expression should be: `example\\.com`

In Perl regular expressions, '*' means match 0 or more times of the character before it, not 0 or more times of any character. For example:

- `exam*.com` matches exammmm.com but does not match example.com

To match any character 0 or more times, use '.*' where '.' means any character and the '*' means 0 or more times. For example, the wildcard match pattern `exam*.com` should be `exam.*\\.com`.

Word boundary

In Perl regular expressions, the pattern does not have an implicit word boundary. For example, the regular expression “test” not only matches the word “test” but also any word that contains “test” such as “atest”, “mytest”, “testimony”, “atestb”. The notation “\b” specifies the word boundary. To match exactly the word “test”, the expression should be \btest\b.

Case sensitivity

Regular expression pattern matching is case sensitive in the web and Email Filter filters. To make a word or phrase case insensitive, use the regular expression /i. For example, /bad language/i will block all instances of “bad language”, regardless of case.

Perl regular expression formats

The following table lists and describes some example Perl regular expressions.

Perl regular expression formats

Expression	Matches
abc	“abc” (the exact character sequence, but anywhere in the string)
^abc	“abc” at the beginning of the string
abc\$	“abc” at the end of the string
a b	Either “a” or “b”
^abc abc\$	The string “abc” at the beginning or at the end of the string
ab{2,4}c	“a” followed by two, three or four “b”s followed by a “c”
ab{2,}c	“a” followed by at least two “b”s followed by a “c”
ab*c	“a” followed by any number (zero or more) of “b”s followed by a “c”
ab+c	“a” followed by one or more b's followed by a c
ab?c	“a” followed by an optional “b” followed by a “c”; that is, either “abc” or “ac”
a.c	“a” followed by any single character (not newline) followed by a “c”
a\.c	“a.c” exactly
[abc]	Any one of “a”, “b” and “c”
[Aa]bc	Either of “Abc” and “abc”
[abc]+	Any (nonempty) string of “a”s, “b”s and “c”s (such as “a”, “abba”, “acbabcacaa”)

Expression	Matches
[^abc]+	Any (nonempty) string which does not contain any of “a”, “b”, and “c” (such as “defg”)
\d\d	Any two decimal digits, such as 42; same as \d{2}
/i	Makes the pattern case insensitive. For example, <code>/bad language/i</code> blocks any instance of <code>bad language</code> regardless of case.
\w+	A “word”: A nonempty sequence of alphanumeric characters and low lines (underscores), such as <code>foo</code> and <code>12bar8</code> and <code>foo_1</code>
100\s*mk	The strings “100” and “mk” optionally separated by any amount of white space (spaces, tabs, newlines)
abc\b	“abc” when followed by a word boundary (for example, in “abc!” but not in “abcd”)
perl\b	“perl” when not followed by a word boundary (for example, in “perlert” but not in “perl stuff”)
\x	Tells the regular expression parser to ignore white space that is neither preceded by a backslash character nor within a character class. Use this to break up a regular expression into (slightly) more readable parts.
/x	Used to add regular expressions within other text. If the first character in a pattern is forward slash '/', the '/' is treated as the delimiter. The pattern must contain a second '/'. The pattern between '/' will be taken as a regular expressions, and anything after the second '/' will be parsed as a list of regular expression options ('i', 'x', etc). An error occurs if the second '/' is missing. In regular expressions, the leading and trailing space is treated as part of the regular expression.

Examples of regular expressions

Block any word in a phrase

```
/block|any|word/
```

Block purposely misspelled words

Spammers often insert other characters between the letters of a word to fool spam blocking software.

```
/^.*v.*i.*a.*g.*r.*o.*$/i
/cr[eéèêë] [\+ \- \* = < > \. \, ; ! \? % & $ @ \^ \° \ $ £ € \{ \} ( ) \[ \] \\\\_01]dit/i
```

Block common spam phrases

The following phrases are some examples of common phrases found in spam messages.

```
/try it for free/i
/student loans/i
/you're already approved/i
/special [\+ \- \* = < > \. \, ; ! \? % & ~ # $ @ \^ \° \ $ £ € \{ \} ( ) \[ \] \\\\_1]offer/i
```

Control how sessions are distributed to Fortinet processes

Previously, the explicit web proxy balanced the client to a specific WAD daemon based only on the source IP. There are cases where customers use another explicit proxy in front of the FortiGate. With such a design, the FortiGate can see the traffic originating from only one IP address (or a small set of IP addresses) and utilize only one (or a small number) of WAD processes.

This new feature modifies the wad-worker balancing algorithm to also use the source port in addition to source IP when distributing the client to a specific WAD daemon. With this in place, even the connections from one IP address will be balanced over all the WAD processes. This also avoids the degraded performance results for the cases where customers are testing the FortiGate as the explicit webproxy to replace Bluecoats, but don't want to remove Bluecoats from the network for the PoC.

Syntax

```
config system global
    set wad-source-affinity {enable | disable}
end
```

This feature is enabled by default. Disabling this option results in some features to be unsupported. IP-based user authentication, disclaimer messages, security profile override, authentication cookies, MAPI scanning, and some video caches such as Youtube are not supported.

CPU allocation and tuning commands to survive reboot

CPU affinity, whereby a process will execute on a specific CPU, can be changed so it survives a reboot.

CLI syntax:

```
config system global
    set av-affinity
    set ips-affinity
    set miglog-affinity
end
```

av-affinity: Affinity setting for AV scanning (64-bit hexadecimal value in the format of xxxxxxxx_xxxxxxxx).

ips-affinity: Affinity setting for IPS (64-bit hexadecimal value in the format of xxxxxxxx_xxxxxxxx; allowed CPUs must be less than total number of IPS engine daemons). This option is only available if the FortiGate includes NP6 processors and support NTurbo.

miglog-affinity: Affinity setting for logging (64-bit hexadecimal value in the format of xxxxxxxx_xxxxxxxx).

Excluding industrial IP signatures

To reduce performance impacts caused by industrial IP signatures, the admin can choose to exclude the industrial signatures when they are loaded by IPS; the industrial signatures then become inactive as a result. The following CLI command has been restored for this purpose.

Syntax

```
config ips global
    set exclude-signatures {none | industrial}
```

end

Chapter 22 - Server Load Balancing

This FortiOS Handbook chapter contains the following sections:

[Inside FortiOS: Server Load Balancing](#) highlights the features and benefits of FortiOS server load balancing.

[Basic load balancing configuration example](#) introduces FortiOS server load balancing by providing a basic configuration example.

[Configuring load balancing](#) describes how to configure FortiOS server load balancing.

[HTTP and HTTPS load balancing, multiplexing, and persistence](#) describes FortiOS server load balancing features that support load balancing HTTP and HTTPS sessions.

[SSL/TLS load balancing](#) describes FortiOS server load balancing features that support load balancing SSL and TLS sessions.

[IP, TCP, and UDP load balancing](#) describes FortiOS server load balancing features that support load balancing IP, TCP, and UDP sessions.

The following configuration examples are also included:

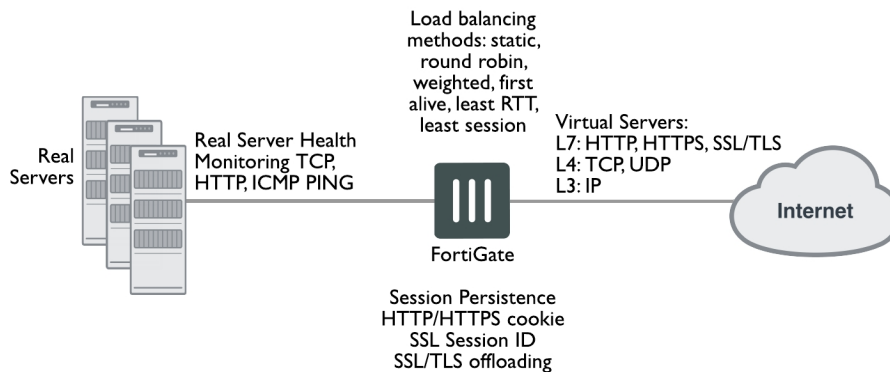

- [Example HTTP load balancing to three real web servers](#)
- [Example Basic IP load balancing configuration](#)
- [Example Adding a server load balance port forwarding virtual IP](#)
- [Example Weighted load balancing configuration](#)
- [Example HTTP and HTTPS persistence configuration](#)

Inside FortiOS: Server Load Balancing

Server load balancing distributes workloads across multiple network servers, allowing simultaneous IPv4, IPv6, IPv4 to IPv6 and IPv6 to IPv4 requests to be handled quickly and reliably.

Server Load Balancing combined with NGFW and UTM protection

By introducing comprehensive server load balancing functionality to Next Generation Firewall (NGFW) and Unified Threat Management (UTM) solutions FortiOS takes threat protection to a whole new level. Rather than going to the expense of deploying multiple solutions to protect your server farm, you can combine firewalling, NGFW, UTM and load balancing into a single FortiGate unit or cluster. The benefit of consolidation is not only limited to cost.

Key Features & Benefits

Increased resilience	A consolidated solution results in significantly simplified network architecture. High availability can be provided for all technologies with just a pair of devices rather than several.
Reduced operational overheads	A unified management solution consisting of a single GUI, logging and reporting, SNMP monitoring and other management functions will significantly reduce the resources required to manage the multiple technology areas. A consolidated solution provides a single point of contact for support and renewals rather than having to deal with multiple vendors.

The FortiOS server load balancing feature set contains all of the features you would expect of a server load balancing solution. Traffic can be balanced across multiple backend servers based on multiple load balancing schedules including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time and number of connections.

The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL/TLS, and generic TCP/UDP and IP protocols. Session persistence is supported based on the SSL session ID, based on an injected HTTP cookie, or based on the HTTP or HTTPS host. SSL/TLS load balancing includes protection from protocol downgrade attacks. Server load balancing is supported on most FortiGate devices and includes up to 10,000 virtual servers on our high end systems.

SSL/TLS offloading

With more and more critical business applications being made available online and in the cloud, the demand for secure remote continues to increase. While securing web and email applications with SSL/TLS is essential, this protection adds significant performance overheads. An SSL/TLS protected application running on a standard server will perform all the costly encryption/decryption and key exchange routines in software which uses vital CPU resources that should be available for running the application. The consequence of this is that many more or more powerful servers are required to deliver the application.

FortiGate SSL/TLS offloading is designed with the explosion of SSL/TLS applications in mind. The key exchange and encryption/decryption tasks are offloaded to the FortiGate unit where they are accelerated using FortiASIC technology providing significantly more performance than a standard server or load balancer could handle. This frees up valuable resources on the server farm which can be used to run a more responsive business. Server load

balancing offloads most SSL/TLS versions including SSL 3.0, TLS 1.0 and TLS 1.2 and supports full mode or half mode SSL offloading with DH key sizes up to 4096 bits.

SSL/TLS content inspection

Traditionally, SSL encrypted application data would be invisible to any border gateway filtering solution. This is because the encryption process prevents the payload of any connection from being seen other than by the communicating systems. FortiGate SSL Offloading allows the application payload to be inspected before it reaches your servers; preventing intrusion attempts, blocking viruses, stopping unwanted applications, and preventing data leakage. SSL/TLS content inspection supports TLS versions 1.0, 1.1, and 1.2 and SSL versions 1.0, 1.1, 1.2, and 3.0.

Health Check

Health checking can be enabled to prevent load balancing traffic from being sent to a non-functioning real server. Real server health can be monitored using ICMP ping or more sophisticated TCP testing. The most comprehensive test is HTTP which verifies that the HTTP application is responding and that it is returning the correct content.

Health checking removes real servers from the load balancing cluster which are returning invalid content. The removal of real servers from the clusters is based on the Interval, Timeout and Retry Settings:

Interval	How often to test the server.
Timeout	What maximum response time is permissible before a server is treated as non-functional.
Retry	How many failures before the server is considered “dead” and removed from the cluster.

Server Monitoring and Management

The health and performance of real servers can be monitored from the FortiGate GUI. Virtual servers and their assigned real servers can be monitored for health status, if there have been any monitor events, number of active sessions, round trip time and number of bytes processed. Should a server become problematic and require administration, it can be gracefully removed from the Real Server pool to enable disruption free maintenance. When a removed real server is able to operate it can gracefully be added back to the virtual server.

HTTP Multiplexing

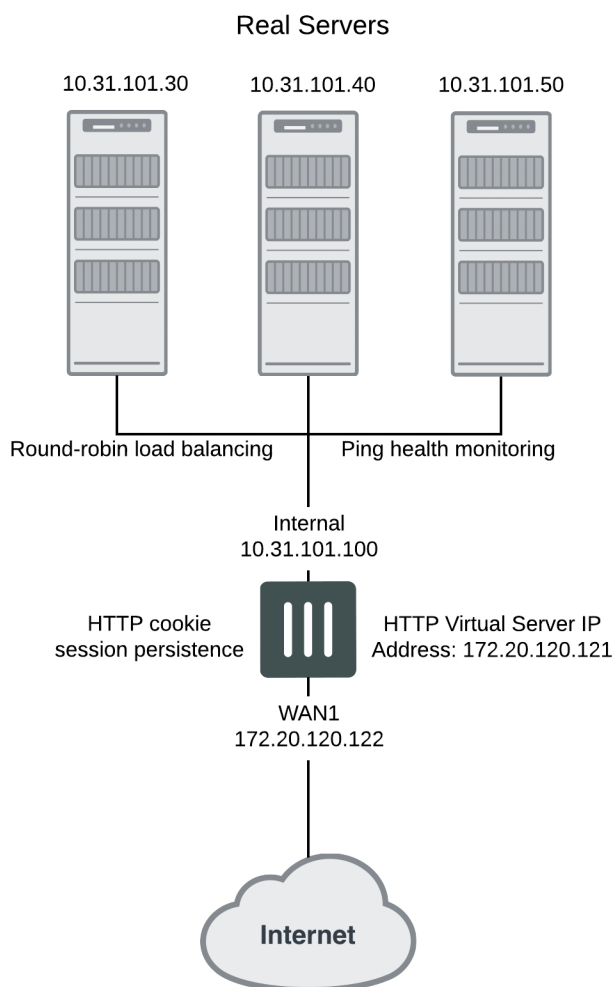

A performance saving feature of HTTP/1.1 compliant web servers is the ability to pipeline requests on the same connection. This allows a single HTTPD process on the server to interleave and server multiple requests. HTTP multiplexing reduces the number idle sessions, too many of which can exhaust the resources on a server. The Fortinet solution has the ability to take multiple separate inbound sessions and multiplex them over the same internal session. This reduces the load on the backend server and increases the overall performance.

Basic load balancing configuration example

This section describes the steps required to configure the load balancing configuration shown below. In this configuration a FortiGate-51B unit is load balancing HTTP traffic from the Internet to three HTTP servers on the Internal network. HTTP sessions are accepted at the wan1 interface with destination IP address 172.20.120.121 on TCP port 8080 and forwarded from the internal interface to the web servers. When forwarded the destination address of the sessions is translated to the IP address of one of the web servers.

The load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to make sure the web servers can respond to network traffic.

Virtual server and real servers setup

To configure the example load balancing configuration - general configuration steps

1. Add a load balance ping health check monitor.
A ping health check monitor causes the FortiGate unit to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.
2. Add a load balance virtual server.
3. Add the three load balance real servers to the virtual server.
4. Add a security policy that includes the load balance virtual server as the destination address.

To configure the example load balancing configuration

1. Go to **Policy & Objects > Health Check** and add the following health check monitor.

Name	Ping-mon-1
Type	Ping
Interval	10 seconds
Timeout	2 seconds
Retry	3

2. Go to **Policy & Objects > Virtual Servers** and add a virtual server that accepts the traffic to be load balanced.

Name	Vserver-HTTP-1
Type	HTTP
Interface	wan1
Virtual Server IP	172.20.120.121
Virtual Server Port	8080
Load Balance Method	Round Robin
Persistence	HTTP Cookie
Health Check	Ping-mon-1
HTTP Multiplexing	Do not select
Preserve Client IP	Do not select

3. On the same GUI page add the real servers to the virtual server.

IP Address	10.31.101.30
Port	80
Max Connections	0
Mode	Active

IP Address	10.31.101.40
Port	80
Max Connections	0
Mode	Active

IP Address	10.31.101.50
Port	80
Max Connections	0
Mode	Active

- Go to **Policy & Objects > IPv4 Policy** and add a wan1 to internal security policy that includes the virtual server. This policy also applies an Antivirus profile to the load balanced sessions.

Name	Example-policy
Incoming Interface	wan1
Outgoing Interface	internal
Source	all
Destination	Vserver-HTTP-1
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Turn on NAT and select Use Outgoing Interface Address .
Antivirus	Turn on and select an Antivirus profile.

- Select **OK**.

To configure the example load balancing configuration from the CLI

- Use the following command to add a Ping health check monitor.

```
config firewall ldb-monitor
edit ping-mon-1
set type ping
set interval 10
set timeout 2
set retry 3
end
```

- Use the following command to add the virtual server that accepts HTTP sessions on port 8080 at the wan1 interface and load balances the traffic to three real servers.

```
config firewall vip
```

```
edit Vserver-HTTP-1
    set type server-load-balance
    set server-type http
    set ldb-method round-robin
    set extip 172.20.120.30
    set extintf wan1
    set extport 8080
    set persistence http-cookie
    set monitor tcp-mon-1
    config realservers
        edit 1
            set ip 10.31.101.30
            set port 80
        next
        edit 2
            set ip 10.31.101.40
            set port 80
        end
        edit 3
            set ip 10.31.101.50
            set port 80
        end
    end
end
```

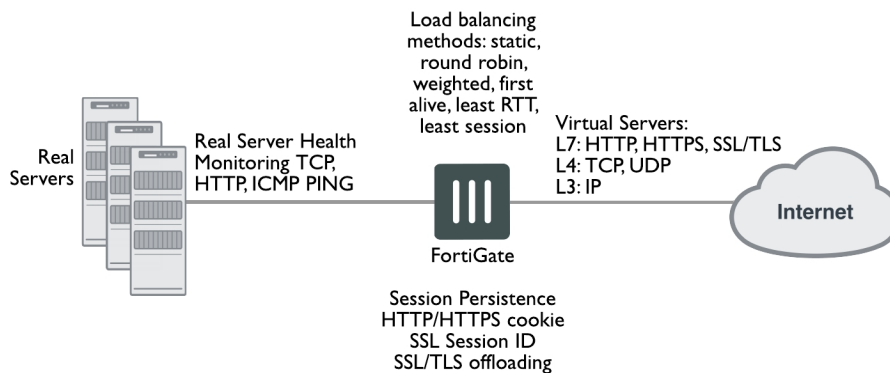

3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
    edit 0
        set srcintf wan1
        set srcaddr all
        set dstintf internal
        set dstaddr Vserver-HTTP-1
        set action accept
        set schedule always
        set service ALL
        set nat enable
        set utm-status enable
        set profile-protocol-options default
        set av-profile scan
    end
```

Configuring load balancing

This section describes how to use the FortiOS server load balancing to load balance traffic to multiple backend servers.

You can configure FortiOS load balancing to intercept incoming traffic with a virtual server and distribute it among one or more backend real servers. By doing so, FortiOS enables multiple real servers to respond as if they were a single device or virtual server. This in turn means that more simultaneous requests can be handled by the servers.

Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

There are additional benefits to load balancing. First, because the load is distributed across multiple servers, the service being provided can be highly available. If one of the servers breaks down, the load can still be handled by the other servers. Secondly, this increases scalability. If the load increases substantially, more servers can be added behind the FortiGate unit to cope with the increased load.

Server load balancing configuration

Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the

virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN. The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

Load balancing and other FortiOS features

Flow-based and proxy-based security features such as virus scanning, IPS, DLP, application control, and web filtering can be applied to load balanced sessions. This includes SSL offloading and multiplexing. Applying these UTM features to load balancing traffic may reduce load balancing performance.

Authentication is not supported for load balancing sessions. Usually FortiGate load balancing is used to allow public access to services on servers protected by a FortiGate unit. Authentication is not generally not required for this kind of configuration.

Features such web proxying, web caching, and WAN optimization also do not work with load balanced sessions. However, most other features that can be applied by a security policy are supported.

Configuring load balancing from the GUI

A virtual server is a specialized firewall virtual IP that performs server load balancing. From the GUI you add load balancing virtual server by going to **Policy & Objects > Virtual Servers**.

You can use the GUI to configure IPv, IPv6, IPv4 to IPv6 (NAT46), or IPv6 to IPv4 (NAT64) load balancing.

Type

Select the type of virtual server to configure. You can select **IPv4**, **IPv6**, **NAT46**, or **NAT64**. If Type is set to NAT46 or NAT64 you have fewer load balancing options (just HTTP, TCP, UDP and IP) and you can't configure advanced SSL and HTTPS load balancing features.

Name

Enter the name for the virtual server.

Type

Select the protocol to be load balanced by the virtual server. If you select a general protocol such as **IP**, **TCP**, or **UDP** the virtual server load balances all IP, TCP, or UDP sessions. If you select specific protocols such as **HTTP**, **HTTPS**, or **SSL** you can apply additional server load balancing features such as **Persistence** and **HTTP Multiplexing**.

- Select **HTTP** to load balance only HTTP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 80 for HTTP sessions). You can also select **HTTP Multiplex**. You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence.
- Select **HTTPS** to load balance only HTTPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 443 for HTTPS sessions). You can also select **Multiplex HTTP requests/responses**. You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence. You can also set **Persistence** to **SSL Session ID**.

- Select **IMAPS** to load balance only IMAPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 993 for IMAPS sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **POP3S** to load balance only POP3S sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 995 for POP3S sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **SMTPS** to load balance only SMTPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 465 for SMTPS sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **SSL** to load balance only SSL sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **TCP** to load balance only TCP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **UDP** to load balance only UDP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **IP** to load balance all sessions accepted by the security policy that contains this virtual server.

Interface

Select the virtual server external or outgoing interface from the list. The outgoing interface is connected to the source network and receives the packets to be forwarded to the destination network.

Virtual Server IP

The IPv4 address of the virtual server. This is an IP address on the external interface that you want to map to an address on the destination network.

Virtual Server Port

Enter the external port number that you want to map to a port number on the destination network. Sessions with this destination port are load balanced by this virtual server.

Load Balance Method

Select the load balancing method used by the virtual server.

Persistence

Configure persistence to make sure that a user is connected to the same server every time they make a request that is part of the same session. Session persistence is supported for HTTP and SSL sessions.

Health Check

Select which health check monitor configuration will be used to determine a server's connectivity status.

HTTP Multiplexing

Select to use the FortiGate unit to multiplex multiple client connections into a few connections between the FortiGate unit and the real server.

Preserve Client IP

Select to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.

This option appears only if **Type** is set to HTTP or HTTPS.

SSL Offloading

Accelerate clients' SSL connections to the server by using the FortiGate to perform SSL operations. This option appears only if **Type** is set to one of the SSL protocols.

Mode

Select which segments of the SSL connection will receive SSL offloading. You can select **Client <-> FortiGate** (or half mode) or **Full** (full mode).

This option appears only if **Type** is set to one of the SSL protocols.

Certificate

Select the certificate to use with **SSL Offloading**. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

This option appears only if **Type** is set to one of the SSL protocols.

Real Servers

Add Real Servers to the virtual server. The virtual server load balances traffic to these real servers. See [Real servers on page 2607](#).

Configuring load balancing from the CLI

From the CLI you configure IPv4 load balancing by adding a firewall virtual IP and setting the virtual IP type to server load balance:

```
config firewall vip
    edit Vserver-HTTP-1
        set type server-load-balance
    ...
```

Sever load balancing is also supported for:

- IPv6 using the command `config firewall vip6`
- IPv6 to IPv4 using the command `config firewall vip64`
- IPv4 to IPv6 using the commmand `config firewall vip46`

Configuration is the same as IPv4 VIPs except support for advanced HTTP and SSL related features is not available. IPv6 server load balancing supports all the same server types as IPv4 server load balancing (HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL, TCP, UDP, and IP). IPv4 to IPv6 and IPv6 to IPv4 server load balancing supports fewer server types (HTTP, TCP, UDP, and IP).

A virtual server includes a virtual server IP address bound to an interface. The virtual server IP address is the destination address incoming packets to be load balanced and the virtual server is bound to the interface that receives the packets to be load balanced.

For example, if you want to load balance incoming HTTP traffic from the Internet to a group of web servers on a DMZ network, the virtual server IP address is the known Internet IP address of the web servers and the virtual server binds this IP address to the FortiGate interface connected to the Internet.

When you bind the virtual server's external IP address to a FortiGate unit interface, by default, the network interface responds to ARP requests for the bound IP address. Virtual servers use proxy ARP, as defined in [RFC 1027](#), so that the FortiGate unit can respond to ARP requests on a network for a real server that is actually installed on another network. In some cases you may not want the network interface sending ARP replies. You can use the `arp-reply` option to disable sending ARP replies:

```
config firewall vip
  edit Vserver-HTTP-1
    set type server-load-balance
    set arp-reply disable
  ...
```

The load balancing virtual server configuration also includes the virtual server port. This is the TCP port on the bound interface that the virtual server listens for traffic to be load balanced on. The virtual server can listen on any port.

Load balancing methods

The load balancing method defines how sessions are load balanced to real servers. A number of load balancing methods are available as listed below.

All load balancing methods will not send traffic to real servers that are down or not responding. However, the FortiGate unit can only determine if a real server is not responding by using a health check monitor. You should always add at least one health check monitor to a virtual server or to individual real servers, or load balancing methods may attempt to distribute sessions to real servers that are not functioning.

Static

The traffic load is statically spread evenly across all real servers. However, sessions are not assigned according to how busy individual real servers are. This load balancing method provides some persistence because all sessions from the same source address always go to the same real server. However, the distribution is stateless, so if a real server is added or removed (or goes up or down) the distribution is changed and persistence could be lost.

Round Robin

Directs new requests to the next real server, and treats all real servers as equals regardless of response time or number of connections. Dead real servers or non responsive real servers are avoided.

Weighted

Real servers with a higher weight value receive a larger percentage of connections. Set the real server weight when adding a real server.

Least Session

Directs requests to the real server that has the least number of current connections. This method works best in environments where the real servers or other equipment you are load balancing all have similar capabilities. This load balancing method uses the FortiGate session table to track the number of sessions being processed by each real server. The FortiGate unit cannot detect the number of sessions actually being processed by a real server.

Least RTT

Directs sessions to the real server with the least round trip time. The round trip time is determined by a Ping health check monitor and is defaulted to 0 if no Ping health check monitors are added to the virtual server.

First Alive

Always directs sessions to the first alive real server. This load balancing schedule provides real server failover protection by sending all sessions to the first alive real server and if that real server fails, sending all sessions to the next alive real server. Sessions are not distributed to all real servers so all sessions are processed by the “first” real server only.

First refers to the order of the real servers in the virtual server configuration. For example, if you add real servers A, B and C in that order, then all sessions always go to A as long as it is alive. If A goes down then sessions go to B and if B goes down sessions go to C. If A comes back up sessions go back to A. Real servers are ordered in the virtual server configuration in the order in which you add them, with the most recently added real server last. If you want to change the order you must delete and re-add real servers in the required order.

HTTP Host

Load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server.

Session persistence

Use persistence to make sure that a user is connected to the same real server every time they make an HTTP, HTTPS, or SSL request that is part of the same user session. For example, if you are load balancing HTTP and HTTPS sessions to a collection of eCommerce web servers, when a user is making a purchase they will be starting multiple sessions as they navigate the eCommerce site. In most cases all of the sessions started by this user during on eCommerce session should be processed by the same real server. Typically, the HTTP protocol keeps track of these related sessions using cookies. HTTP cookie persistence makes sure that all sessions that are part of the same user session are processed by the same real server

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the load balance method. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server. For more information about HTTP and HTTPS persistence, see [“HTTP and HTTPS persistence”](#).

Real servers

Add real servers to a load balancing virtual server to provide the information the virtual server requires to be able to send sessions to the server. A real server configuration includes the IP address of the real server and port number that the real server receives sessions on. The FortiGate unit sends sessions to the real server's IP address using the destination port number in the real server configuration.

When configuring a real server you can also specify the weight (used if the load balance method is set to weighted) and you can limit the maximum number of open connections between the FortiGate unit and the real server. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests other real servers until the connection number drops below the specified limit. Setting Maximum Connections to 0 means that the FortiGate unit does not limit the number of connections to the real server.

Real server active, standby, and disabled modes

By default the real server mode setting is active indicating that the real server is available to receive connections. If the real server is removed from the network (for example, for routine maintenance or because of a hardware or software failure) you can change the mode to standby or disabled. In disabled mode the FortiGate unit no longer sends sessions to the real server.

If a real server is in standby mode the FortiGate also does not send sessions to it unless other real servers added to the same virtual server become unavailable. For example:

- A virtual server that includes two real servers one in active mode and one in standby mode. If the real server in active mode fails, the real server in standby mode is changed to active mode and all sessions are sent to this real server.
- A virtual server includes three real servers, two in active mode and one in standby mode, if one of the real servers in active mode fails, the real server in standby mode is changed to active mode and sessions are load balanced between it and still operating real server. If both real servers in active mode fail, all sessions are sent to the real server in standby mode.

Adding real servers from the GUI

To add a real server from the GUI go to **Policy & Objects > Virtual Servers**, edit a virtual server and under **Real Servers** select **Create New** to add a real server to this virtual server.

IP Address

Enter the IP address of the real server.

Port

Enter the port number on the destination network to which the external port number is mapped.

Weight

Enter the weight value of the real server. The higher the weight value, the higher the percentage of connections the server will handle. A range of 1-255 can be used. This option is available only if the associated virtual server's load balance method is **Weighted**.

Max Connections

Enter the limit on the number of active connections directed to a real server. A range of 1-99999 can be used. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests to another server until the connection number drops below the specified limit.

Setting **Maximum Connections** to **0** means that the FortiGate unit does not limit the number of connections to the real server.

HTTP Host

Enter the HTTP header for load balancing across multiple real servers. This feature is used for load balancing HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server, providing better load balancing for those specific connections.

Mode

Select a mode for the real server. The real server can be active, on standby, or disabled.

Adding real servers from the CLI

To add a real server from the CLI you configure a virtual server and add real servers to it. For example, to add three real servers to a virtual server that load balances UDP sessions on port 8190 using weighted load balancing. For each real server the port is not changed. The default real server port is 0 resulting in the traffic being sent the real server with destination port 8190. Each real sever is given a different weight. Servers with higher weights have a max-connections limit to prevent too many sessions from being sent to them.

```
config firewall vip
  edit Vserver-UDP-1
    set type server-load-balance
    set server-type udp
    set ldb-method weighted
    set extip 172.20.120.30
    set extintf wan1
    set extport 8190
    set monitor ping-mon-1
    config realservers
      edit 1
        set ip 10.31.101.30
        set weight 100
        set max-connections 10000
      next
      edit 2
        set ip 10.31.101.40
        set weight 100
        set max-connections 10000
      next
      edit 3
        set ip 10.31.101.50
        set weight 10
      end
    end
end
```

Health check monitoring

From the FortiGate GUI you can go to **Policy & Objects > Health Check** and configure health check monitoring so that the FortiGate unit can verify that real servers are able respond to network connection attempts. If a real server responds to connection attempts the load balancer continues to send sessions to it. If a real server stops responding to connection attempts the load balancer assumes that the server is down and does not send sessions to it. The health check monitor configuration determines how the load balancer tests the real servers. You can use a single health check monitor for multiple load balancing configurations.

You can configure TCP, HTTP and Ping health check monitors. Usually you would want the health check monitor to use the same protocol for checking the health of the server as the traffic being load balanced to it. For example, for an HTTP load balancing configuration you would normally use an HTTP health check monitor.

For the TCP and HTTP health check monitors you can specify the destination port to use to connect to the real servers. If you set the port to 0, the health check monitor uses the port defined in the real server. This allows you to use the same health check monitor for multiple real servers using different ports. You can also configure the interval, timeout and retry. A health check occurs every number of seconds indicated by the interval. If a reply is

not received within the timeout period the health check is repeated every second. If no response is received after the number of configured retries, the virtual server is considered unresponsive, and load balancing does not send traffic to that real server. The health check monitor will continue to contact the real server and if successful, the load balancer can resume sending sessions to the recovered real server.

The default health check configuration has an interval of 10 seconds, a timeout of 2 seconds and a retry of 3. This means that the health check monitor checks the health of a real server every 10 seconds. If a reply is not received within 2 seconds the health check monitor re-checks the server every second for 3 retries. If no response is received for 2 seconds after the final retry the server is considered unresponsive. This entire process takes a total of 7 seconds to consider a virtual server as unresponsive (2 second timeout + (3 re-checks x 1 second) + 2 second timeout = 7 seconds). Since this health check process is repeated every 10 seconds, a server can be down for a maximum of $10 + 7 = 17$ seconds before the health check monitor considers it down.

For HTTP health check monitors, you can add URL that the FortiGate unit connects to when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a "/" and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.31.101.30, the URL "/test_page.htm" causes the FortiGate unit to send an HTTP get request to "http://10.31.101.30/test_page.htm".

For HTTP health check monitors, you can also add a matched content phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the URL option. If the URL returns a web page, the matched content should exactly match some of the text on the web page. You can use the URL and Matched Content options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set matched content to "server test page" if the real HTTP server page defined by the URL option contains the phrase "server test page". When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the matched content phrase.

Name

Enter the name of the health check monitor configuration.

Type

Select the protocol used to perform the health check.

- TCP
- HTTP
- PING

Port

Enter the port number used to perform the health check. If you set the **Port** to 0, the health check monitor uses the port defined in the real server. This way you can use a single health check monitor for different real servers.

This option does not appear if the **Type** is **PING**.

Interval

Enter the number of seconds between each server health check.

URL

For HTTP health check monitors, add a URL that the FortiGate unit uses when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a “/” and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.10.10.1, the **URL** “/test_page.htm” causes the FortiGate unit to send an HTTP get request to “http://10.10.10.1/test_page.htm”.

This option appears only if **Type** is **HTTP**.

Matched Content

For HTTP health check monitors, add a phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the **URL** option. If the **URL** returns a web page, the **Matched Content** should exactly match some of the text on the web page. You can use the **URL** and **Matched Content** options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set **Matched Content** to “server test page” if the real HTTP server page defined by the URL option contains the phrase “server test page”. When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the **Matched Content** phrase.

This option appears only if **Type** is **HTTP**.

Max Redirects

For an HTTP health check monitor, specify the maximum number of redirects that the health check monitor will follow when testing the health of the real HTTP server. This feature allows you to do health checking of the HTTP server is accessed through one or more redirects.

Timeout

Enter the number of seconds which must pass after the server health check to indicate a failed health check.

Retry

Enter the number of times, if any, a failed health check will be retried before the server is determined to be inaccessible.

Load balancing limitations

The following limitations apply when adding virtual IPs, load balancing virtual servers, and load balancing real servers. Load balancing virtual servers are actually server load balancing virtual IPs. You can add server load balance virtual IPs from the CLI.

- Virtual IP **External IP Address/Range** entries or ranges cannot overlap with each other or with load balancing virtual server **Virtual Server IP** entries.
- A virtual IP **Mapped IP Address/Range** cannot be 0.0.0.0 or 255.255.255.255.
- A real server **IP** cannot be 0.0.0.0 or 255.255.255.255.
- If a static NAT virtual IP **External IP Address/Range** is 0.0.0.0, the **Mapped IP Address/Range** must be a single IP address.

- If a load balance virtual IP **External IP Address/Range** is 0.0.0.0, the **Mapped IP Address/Range** can be an address range.
- When port forwarding, the count of mapped port numbers and external port numbers must be the same. The GUI does this automatically but the CLI does not.
- Virtual IP and virtual server names must be different from firewall address or address group names.

Monitoring load balancing

From the GUI you can go to **Monitor > Load Balance Monitor** to monitor the status of configured virtual servers and real servers and start or stop the real servers. You can also use the `get test ipldb` command from the CLI to display similar information.

For each real server the monitor displays health status (up or down), active sessions, round trip time (RTT) and the amount of bytes of data processed. From the monitor page you can also stop sending new sessions to any real server. When you select to stop sending sessions the FortiGate unit performs a graceful stop by continuing to send data for sessions that were established or persistent before you selected stop. However, no new sessions are started.

Real Server

The IP addresses of the existing real servers.

Status

Displays the health status according to the health check results for each real server. A green arrow means the server is up. A red arrow means the server is down.

Mode

The mode of the health check monitor. Can be active, standby, or disabled.

Monitor Events

Display each real server's up and down times.

Active Sessions

Display each real server's active sessions.

RTT (ms)

Displays the Round Trip Time (RTT) of each real server. By default, the RTT is "<1". This value will change only when ping monitoring is enabled on a real server.

Bytes Processed

Displays the traffic processed by each real server.

Graceful Stop/Start

Select to start or stop real servers. When stopping a server, the FortiGate unit will not accept new sessions but will wait for the active sessions to finish.

Load balancing diagnose commands

You can also use the following diagnose commands to view status information for load balancing virtual servers and real servers:

```
diagnose firewall vip realserver {down | healthcheck | list | up}
diagnose firewall vip virtual-server {filter | real-server | stats}
```

For example, the following command lists and displays status information for all real servers:

```
diagnose firewall vip virtual-server real-server

vd root/0 vs vs/2 addr 10.31.101.30:80 status 1/1
conn: max 0 active 0 attempts 0 success 0 drop 0 fail 0

vd root/0 vs vs/2 addr 10.31.101.20:80 status 1/1
conn: max 0 active 0 attempts 0 success 0 drop 0 fail 0
```

Many of the diagnostic commands involve retrieving information about one or more virtual servers. To control which servers are queried you can define a filter:

```
diagnose firewall vip virtual-server filter <filter_str>
```

Where <filter_str> can be:

- **clear** erase the current filter
- **dst** the destination address range to filter by
- **dst-port** the destination port range to filter by
- **list** display the current filter
- **name** the vip name to filter by
- **negate** negate the specified filter parameter
- **src** the source address range to filter by
- **src-port** the source port range to filter by
- **vd** index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Logging diagnostics

The logging diagnostics provide information about two separate features:

```
diagnose firewall vip virtual-server filter
```

- **filter** sets a filter for the virtual server debug log
- The filter option controls what entries the virtual server daemon will log to the console if **diagnose debug application vs** level is non-zero. The filtering can be done on source, destination, virtual-server name, virtual domain, and so on:

```
diagnose firewall vip virtual-server filter <filter_str>
```

Where <filter_str> can be

- **clear** erase the current filter
- **dst** the destination address range to filter by
- **dst-port** the destination port range to filter by
- **list** display the current filter
- **name** the virtual-server name to filter by
- **negate** negate the specified filter parameter

- `src` the source address range to filter by
- `src-port` the source port range to filter by
- `vd` index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Real server diagnostics

Enter the following command to list all the real servers:

```
diagnose firewall vip virtual-server real-server list
```

In the following example there is only one virtual server called `slb` and it has two real-servers:

```
diagnose firewall vip virtual-server server
vd root/0 vs slb/2 addr 172.16.67.191:80 status 1/1
conn: max 10 active 0 attempts 0 success 0 drop 0 fail 0
http: available 0 total 0

vd root/0 vs slb/2 addr 172.16.67.192:80 status 1/1
conn: max 10 active 1 attempts 4 success 4 drop 0 fail 0
http: available 1 total 1
```

The `status` indicates the administrative and operational status of the real-server.

- `max` indicates that the real-server will only allow 10 concurrent connections.
- `active` is the number of current connections to the server attempts is the total number of connections attempted success is the total number of connections that were successful.
- `drop` is the total number of connections that were dropped because the active count hit max.
- `fail` is the total number of connections that failed to complete due to some internal problem (for example, lack of memory).

If the virtual server has HTTP multiplexing enabled then the HTTP section indicates how many established connections to the real-server are available to service a HTTP request and also the total number of connections.

HTTP and HTTPS load balancing, multiplexing, and persistence

In a firewall load balancing virtual server configuration, you can select HTTP to load balance only HTTP sessions. The virtual server will load balance HTTP sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. The default virtual server port for HTTP load balancing is 80, but you can change this to any port number. Similarly for HTTPS load balancing, set the virtual server type to HTTPS and then select the interface, virtual server IP, and virtual server port that matches the HTTPS traffic to be load balanced. Usually HTTPS traffic uses port 443.

You can also configure load balancing to offload SSL processing for HTTPS and SSL traffic. See [SSL/TLS load balancing on page 2619](#).

HTTP and HTTPS multiplexing

For both HTTP and HTTPS load balancing you can multiplex HTTP requests and responses over a single TCP connection. HTTP multiplexing is a performance saving feature of HTTP/1.1 compliant web servers that provides the ability to pipeline many unrelated HTTP or HTTPS requests on the same connection. This allows a single HTTPD process on the server to interleave and serve multiple requests. The result is fewer idle sessions on the

web server so server resources are used more efficiently. HTTP multiplexing can take multiple separate inbound sessions and multiplex them over the same internal session. This may reduce the load on the backend server and increase the overall performance.

HTTP multiplexing may improve performance in some cases. For example, if users web browsers are only compatible with HTTP 1.0. HTTP multiplexing can also improve performance between a web server and the FortiGate unit if the FortiGate unit is performing SSL acceleration. However, in most cases HTTP multiplexing should only be used if enabling it leads to a measurable improvement in performance.

To enable HTTP multiplexing from the GUI, select multiplex HTTP requests/responses over a single TCP connection. To enable HTTP multiplexing from the CLI enable the `http-multiplex` option.

Preserving the client IP address

Select preserve client IP from the GUI or enable the `http-ip-header` option from the CLI to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful in an HTTP multiplexing configuration if you want to be able to see the original client IP address in log messages on the destination web server. If this option is not selected, the `X-Forwarded-For` HTTP header contains the IP address of the FortiGate unit.

Preserving the client IP address in a different HTTP header

If you select preserve client IP from the GUI or enable the `http-ip-header` option from the CLI you can also preserve the client IP in a different HTTP header. This can be useful if you want to use a custom header name instead of `X-Forwarded-For`.

You can add the custom header name from the CLI. When `http-ip-header` is enabled you can add a custom header name to the `http-ip-header-name` option. If you don't add a name the `X-Forwarded-For` header is used.

HTTP and HTTPS persistence

Configure load balancing persistence for HTTP or HTTPS to make sure that a user is connected to the same server every time they make a request that is part of the same session. HTTP cookie persistence uses injected cookies to enable persistence.

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the **Load Balance Method**. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server.

The following example shows how to enable cookie persistence and set the cookie domain to `.example.org`.

```
config firewall vip
  edit HTTP_Load_Balance
    set type server-load-balance
    set server-type http
    set extport 8080
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
    config realservers
    edit 1
      set ip 10.10.10.1
      set port 80
    next
```

```

edit 2
    set ip 10.10.10.2
    set port 80
next
edit 3
    set ip 10.10.10.3
    set port 80
end

```

How HTTP cookie persistence options work

The following options are available for the `config firewall vip` command when `type` is set to `server-load-balance`, `server-type` is set to `http` or `https` and `persistence` is set to `http-cookie`:

```

http-cookie-domain-from-host
http-cookie-domain
http-cookie-path
http-cookie-generation
http-cookie-age
http-cookie-share
https-cookie-share

```

When HTTP cookie persistence is enabled the FortiGate unit inserts a header of the following form into each HTTP response unless the corresponding HTTP request already contains a `FGTServer` cookie:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1; Max-Age=3600
```

The value of the `FGTServer` cookie encodes the server that traffic should be directed to. The value is encoded so as to not leak information about the internal network.

Enable `http-cookie-domain-from-host` to extract the cookie domain from the `host:` header in the HTTP request. For example, to restrict the cookie to `.server.com`, enter:

The generated cookies could have the following form if the **Host:** header contains **exhost.com**:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
Domain=.exhost.com; Max-Age=3600
```

For more information, see [“HTTP host-based load balancing”](#).

Use `http-cookie-domain` to restrict the domain that the cookie should apply to. For example, to restrict the cookie to `.server.com`, enter:

```
set http-cookie-domain .server.com
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
Domain=.server.com; Max-Age=3600
```

Use `http-cookie-path` to limit the cookies to a particular path. For example, to limit cookies to the path `/sales`, enter:

```
set http-cookie-path /sales
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
Domain=.server.com; Path=/sales; Max-Age=3600
```

Use `http-cookie-age` to change how long the browser caches the cookie. You can enter an age in minutes or set the age to 0 to make the browser keep the cookie indefinitely:

```
set http-cookie-age 0
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTSer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
Domain=.server.com; Path=/sales
```

Use `http-cookie-generation` to invalidate all cookies that have already been generated. The exact value of the generation is not important, only that it is different from any generation that has already been used for cookies in this domain. The simplest approach is to increment the generation by one each time invalidation is required. Since the default is 0, enter the following to invalidate all existing cookies:

```
set http-cookie-generation 1
```

Use `http-cookie-share {disable | same-ip}` to control the sharing of cookies across virtual servers in the same virtual domain. The default setting `same-ip` means that any `FGTSer` cookie generated by one virtual server can be used by another virtual server in the same virtual domain. For example, if you have an application that starts on HTTP and then changes to HTTPS and you want to make sure that the same server is used for the HTTP and HTTPS traffic then you can create two virtual servers, one for port 80 (for HTTP) and one for port 443 (for HTTPS). As long as you add the same real servers to both of these virtual servers (and as long as both virtual servers have the same number of real servers with the same IP addresses), then cookies generated by accessing the HTTP server are reused when the application changes to the HTTPS server.

If for any reason you do not want this sharing to occur then select `disable` to make sure that a cookie generated for a virtual server cannot be used by other virtual servers.

Use `https-cookie-secure` to enable or disable using secure cookies. Secure cookies are disabled by default because secure cookies can interfere with cookie sharing across HTTP and HTTPS virtual servers. If enabled, then the `Secure` tag is added to the cookie inserted by the FortiGate unit:

```
Set-Cookie: FGTSer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1; Max-Age=3600;
Secure
```

HTTP host-based load balancing

When configuring HTTP or HTTPS load balancing you can select HTTP host load balancing to load balance HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server. HTTP 1.1 includes the concept of a virtual server which allows a HTTP or HTTPS server with a single external IP address to serve requests for multiple DNS domains by using the mandatory `Host:` header in a HTTP request to indicate which DNS domain the request is destined for.

FortiOS can load-balance HTTP and HTTPS connections among multiple real servers using the `Host:` header to guide the connection to the correct real server. The host load balancing method allows a real server to specify a `http-host` attribute which is the domain name of the traffic for that real server. Each real server can only specify a single domain name. The same domain name can appear in more than one real server but only the first one that is up will be used, any others are purely for redundancy. If the `Host:` header contains a domain that does not match any `http-host` entry then the connection will be dropped. A real server with no `http-host` can be matched by any `Host:` domain.

For example, consider a FortiGate unit that is load-balancing traffic to three real servers. Traffic for `www.example1.com` should go to `192.168.2.1`, traffic for `www.example2.com` should go to `192.168.2.2` and traffic to any other domain should go to `192.168.2.3`. To enable this configuration you would add a virtual server and set the load balance method to HTTP host. Then you would add three real servers and set the HTTP host of the real server with IP address `192.168.2.1` to `www.example1.com`, the HTTP host of the real server with IP address `192.168.2.2` to `www.example2.com` and you would not specify an HTTP host for the third real server.

The configuration of a virtual IP to achieve this result would be:

```
config firewall vip
edit "http-host-ldb"
set type server-load-balance
```

```
set extip 172.16.67.195
set extintf "lan"
set server-type http
set ldb-method http-host
set extport 80
config realservers
edit 1
    set http-host "www.example1.com"
    set ip 192.168.2.1
    set port 80
next
edit 2
    set http-host "www.example2.com"
    set ip 192.168.2.2
    set port 80
next
edit 3
    set ip 192.168.2.3
    set port 80
next
end
```

Host load balancing and HTTP cookie persistence

In an HTTP host-based load balancing configuration with HTTP cookie persistence enabled you can optionally configure cookie persistence to use the domain set in the host header as the cookie domain. You can do this by enabling the `http-cookie-domain-from-host` option, for example:

```
config firewall vip
edit "http-host-ldb"
    set type server-load-balance
    set extip 172.16.67.195
    set extintf "lan"
    set server-type http
    set ldb-method http-host
    set extport 80
    set persistence http-cookie
    set http-cookie-domain-from-host enable
    config realservers
        edit 1
            set http-host "www.example1.com"
            set ip 192.168.2.1
            set port 80
        next
        edit 2
            set http-host "www.example2.com"
            set ip 192.168.2.2
            set port 80
        next
        edit 3
            set ip 192.168.2.3
            set port 80
        next
    end
end
```

SSL/TLS load balancing

In a firewall load balancing virtual server configuration, you can select SSL to load balance only SSL and TLS sessions. The virtual server will load balance SSL and TLS sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. Change this port to match the destination port of the sessions to be load balanced.

For SSL load balancing you can also set persistence to SSL session ID. Persistence is achieved by the FortiGate unit sending all sessions with the same SSL session ID to the same real server. When you configure persistence, the FortiGate unit load balances a new session to a real server according to the **Load Balance Method**. If the session has an SSL session ID, the FortiGate unit sends all subsequent sessions with the same SSL session ID to the same real server.

SSL/TLS offloading

Use SSL offloading to accelerate clients' SSL or HTTPS connections to real servers by using the FortiGate unit to perform SSL/TLS operations (offloading them from the real servers using the FortiGate unit's SSL acceleration hardware). FortiGate units can offload most versions of SSL/TLS, including SSL 3.0, TLS 1.0 and TLS 1.2. SSL/TLS offloading is available on FortiGate units that support SSL acceleration.

To configure SSL offloading from the GUI go to **Policy & Objects > Virtual Servers**. Add a virtual server and set the type to HTTPS or SSL and select the SSL offloading type (**Client <-> FortiGate** or **Full**).

Select **Client <-> FortiGate** to apply hardware accelerated SSL/TLS processing only to the part of the connection between the client and the FortiGate unit. This mode is called half mode SSL offloading. The segment between the FortiGate unit and the server will use clear text communications. This results in best performance, but cannot be used in failover configurations where the failover path does not have an SSL accelerator.

Select **Full** to apply hardware accelerated SSL processing to both parts of the connection: the segment between client and the FortiGate unit, and the segment between the FortiGate unit and the server. The segment between the FortiGate unit and the server uses encrypted communications, but the handshakes are abbreviated. This is not as efficient as half mode SSL offloading, but still improves performance. As well, full-mode SSL offloading can be used in failover configurations where the failover path does not have an SSL accelerator. If the server is already configured to use SSL, this also enables SSL acceleration without requiring changes to the server's configuration.

SSL Offloading modes (Half Mode and Full Mode)

Configuring SSL offloading also requires selecting a certificate to use for the SSL offloading sessions. SSL offloading supports key sizes up to 4096. FortiGate models with CP9 processors support 3072 and 4096 DH bit sizes in hardware. All FortiGate models up to and including those with CP8 processors only support offloading DH bit sizes up to 2048 so any sizes larger than that are done in software and thus are relatively resource intensive.

The following CLI command shows an example half mode HTTPS SSL offloading configuration. In the example the `ssl-mode` option sets the SSL offload mode to `half` (which is the default mode).

```
config firewall vip
  edit Vserver-ssl-offload
    set type server-load-balance
    set server-type https
    set ldb-method round-robin
    set extip 172.20.120.30
    set extintf wan1
    set extport 443
```

```
set persistence ssl-session-id
set ssl-mode half
set ssl-certificate my-cert
set monitor tcp-mon-1
config realservers
  edit 1
    set ip 10.31.101.30
    set port 443
  next
  edit 2
    set ip 10.31.101.40
    set port 443
  end
end
```

Separate virtual-server client and server TLS version and cipher configuration

In some cases, you may want the to use different versions of SSL or TLS on the client to FortiGate connection than on the FortiGate to server connection. For example, you may want to use the FortiGate to protect a legacy SSL 3.0 or TLS 1.0 server while making sure that client to FortiGate connections must always use the higher level of protection offered by TLS 1.1 or greater. Also, in some cases you might want to protect a server that only has weak ciphers (for example, DES or RC4) while making sure that all connections between the FortiGate and the client use a strong cipher for better protection.

The following options are available when configuring server load balancing for HTTPS sessions configured with the following command:

```
config firewall vip
  edit server-name
    set type server-load-balance
    set server-type https
    set ssl-mode full
  ...
```

Setting the SSL/TLS versions to use for server and client connections

The `ssl-server-min-version`, `ssl-server-max-version`, `ssl-min-version` and `ssl-max-version` configuration options allow the minimum and maximum SSL/TLS versions for the client to FortiGate connection to be independent of the FortiGate to server configuration. By default these options are both set to `client` and the configured `ssl-min-version` and `ssl-max-version` settings are applied to both the client and the server connection.

You can change the `ssl-server-min-version` and `ssl-server-max-version` to apply different options to the server connection. The `ssl-min-version` and `ssl-max-version` settings are still applied to the client connection. If you set the `ssl-server-min-version` and `ssl-server-max-version` to an explicit version then both must be set to an explicit version.

The `ssl-server-min-version` and `ssl-server-max-version` options allow you to specify the minimum and maximum SSL/TLS versions the FortiGate will offer to the server (in the record header of the ClientHello) when performing full mode SSL offloading and thus the minimum and maximum SSL/TLS versions the FortiGate accepts from the server (in a ServerHello). If the server responds with a version in its ServerHello that is lower than `ssl-server-min-version` or higher than the `ssl-server-max-version` then the FortiGate terminates the connection.

Command syntax is:

```

config firewall vip
edit server-name
set type server-load-balance
set server-type https
set ssl-mode full
set ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
set ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
set ssl-server-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}
set ssl-server-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2 | client}

```

Setting the SSL/TLS cipher choices for server and client connections

The `ssl-algorithm` and `ssl-server-algorithm` configuration options allow the cipher choice for the FortiGate to server connection to be independent of the client to FortiGate connection. By default, `ssl-server-algorithm` is set to `client` and the configured `ssl-algorithm` setting is applied to both the client and the server connection.

You can change the `ssl-server-algorithm` to apply different options to the server connection. The `ssl-algorithm` setting is still applied to the client connection.

The following `ssl-server-algorithm` options are available:

- `high`, offer AES or 3DES cypher suites in the ServerHello
- `medium`, use AES, 3DES, or RC4 cypher suites in the ServerHello
- `low`, use AES, 3DES, RC4, or DES cypher suites in the ServerHello
- `custom`, specify custom cypher suites using the `config ssl-server-cipher-suites` and offer these custom cypher suites in the ServerHello.
- `client`, offer the cypher suites in the ServerHello that are offered in the ClientHello.

Command syntax is:

```

config firewall vip
edit server-name
set type server-load-balance
set server-type https
set ssl-mode full
set ssl-algorithm {high | medium | low | custom}
set ssl-server-algorithm {high | medium | low | custom | client}

```

If you set `ssl-server-algorithm` to `custom`, the syntax is:

```

config firewall vip
edit server-name
set type server-load-balance
set server-type https
set ssl-mode full
set ssl-server-algorithm custom
config ssl-server-cipher-suites
edit 10
set cipher <cipher-suite>
set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
next
edit 20
set cipher <cipher-suite>
set versions {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}
end

```

Protection from TLS protocol downgrade attacks

The `ssl-client-fallback` option, when enabled (the default configuration), performs downgrade attack prevention (RFC 7507).

Command syntax is:

```
config firewall vip
edit server-name
set type server-load-balance
set server-type https
set ssl-client-fallback {disable | enable}
```

Setting 3072- and 4096-bit Diffie-Hellman values

The `ssl-dh-bits` option allows you to specify the number of bits of the prime number used in the Diffie-Hellman exchange for RSA encryption of the SSL connection. Larger prime numbers are associated with greater cryptographic strength. You can set DH values from 768 to 4096 bits.

Command syntax is:

```
config firewall vip
edit server-name
set type server-load-balance
set server-type https
set ssl-dh-bits {768 | 1024 | 1536 | 2048 | 3072 | 4096}
```

Setting the DH bits to 2048 only provides the equivalent of a symmetric cipher in the range of 112 - 128 bits. This means that if AES 256 is used then the weakest point is the DH of 2048 and a value of at least 3072 should be used if the goal is to have 256 bits of security.

FortiGate models with CP9 processors support 3072 and 4096 DH bit sizes in hardware. All FortiGate models up to and including those with CP8 processors only support offloading DH bit sizes up to 2048 so any sizes larger than that are done in software and thus are relatively resource intensive.

Additional SSL load balancing and SSL offloading options

The following SSL load balancing and SSL offloading options are only available from the CLI:

```
ssl-client-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the client and the FortiGate unit.

```
ssl-client-session-state-type {both | client | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the client and the FortiGate unit.

- **both:** Select to expire SSL session states when either `ssl-client-session-state-max` or `ssl-client-session-state-timeout` is exceeded, regardless of which occurs first.
- **count:** Select to expire SSL session states when `ssl-client-session-state-max` is exceeded.

- **disable:** Select to keep no SSL session states.
- **time:** Select to expire SSL session states when `ssl-client-session-state-timeout` is exceeded.

```
ssl-http-location-conversion {enable | disable}
```

Select to replace `http` with `https` in the reply's `Location` HTTP header field. For example, in the reply, `Location: http://example.com/` would be converted to `Location: https://example.com/`

```
ssl-http-match-host {enable | disable}
```

Enable (the default) to apply `Location` conversion to the reply's HTTP header only if the host name portion of `Location` matches the request's `Host` field, or, if the `Host` field does not exist, the host name portion of the request's URI.

If disabled, conversion occurs regardless of whether the host names in the request and the reply match.

For example, if host matching is enabled, and a request contains `Host: example.com` and the reply contains `Location: http://example.cc/`, the `Location` field does not match the host of the original request and the reply's `Location` field remains unchanged. If the reply contains `Location: http://example.com/`, however, then the FortiGate unit detects the matching host name and converts the reply field to `Location: https://example.com/`.

This option appears only if `ssl-http-location-conversion` is `enable`.

```
ssl-send-empty-frags {enable | disable}
```

Select to precede the record with empty fragments to protect from attacks on CBC IV. You might disable this option if SSL acceleration will be used with an old or buggy SSL implementation which cannot properly handle empty fragments.

```
ssl-server-session-state-max <sessionstates_int>
```

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the server and the FortiGate unit.

```
ssl-server-session-state-timeout <timeout_int>
```

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

```
ssl-server-session-state-type {both | count | disable | time}
```

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

- **both:** Select to expire SSL session states when either `ssl-server-session-state-max` or `ssl-server-session-state-timeout` is exceeded, regardless of which occurs first.
- **count:** Select to expire SSL session states when `ssl-server-session-state-max` is exceeded.
- **disable:** Select to keep no SSL session states.
- **time:** Select to expire SSL session states when `ssl-server-session-state-timeout` is exceeded.

SSL offloading support for Internet Explorer 6

In some cases the Internet Explorer 6 web browser may be able to access real servers. To resolve this issue, disable the `ssl-send-empty-frags` option:

```
config firewall vip
  edit vip_name
    set type server-load-balance
    set server-type https
    set ssl-send-empty-frags disable
  end
```

You can disable this option if SSL acceleration will be used with an old or buggy SSL implementation that cannot properly handle empty fragments.

Selecting the cipher suites available for SSL load balancing

You can use the following command to view the complete list of cipher suites available for SSL offloading:

```
config firewall vip
edit <vip-name>
set type server-load-balance
set server-type https
set ssl-algorithm custom
config ssl-cipher-suites
edit 0
set cipher ?
```

In most configurations the matching cipher suite is automatically selected but you can limit the set of cipher suites that are available for a given SSL offloading configuration. For example, use the following command to limit an SSL load balancing configuration to use the three cipher suites that support ChaCha20 and Poly1305:

```
config firewall vip
edit <vip-name>
set type server-load-balance
set server-type https
set ssl-algorithm custom
config ssl-cipher-suites
edit 1
set cipher TLS-ECDHE-RSA-WITH-CHACHA20-POLY1305-SHA256
next
edit 2
set cipher TLS-ECDHE-ECDSA-WITH-CHACHA20-POLY1305-SHA256
next
edit 3
set cipher TLS-DHE-RSA-WITH-CHACHA20-POLY1305-SHA256
end
end
```

Disabling SSL/TLS re-negotiation

The vulnerability [CVE-2009-3555](#) affects all SSL/TLS servers that support re-negotiation. FortiOS when configured for SSL/TLS offloading is operating as a SSL/TLS server. The IETF is working on a TLS protocol change that will fix the problem identified by CVE-2009-3555 while still supporting re-negotiation. Until that protocol change is available, you can use the `ssl-client-renegotiation` option to disable support for SSL/TLS re-negotiation. The default value of this option is `allow`, which allows an SSL client to renegotiate. You can change the setting to `deny` to abort any attempts by an SSL client to renegotiate. If you select `deny` as soon as a `ClientHello` message indicating a re-negotiation is received from the client FortiOS terminates the TCP connection.

Since SSL offloading does not support requesting client certificates the only circumstance in which a re-negotiation is required is when more than 2³² bytes of data are exchanged over a single handshake. If you are sure that this volume of traffic will not occur then you can disable re-negotiation and avoid any possibility of the attack described in CVE-2009-3555.

The re-negotiation behavior can be tested using OpenSSL. The OpenSSL `s_client` application has the feature that the user can request that it do renegotiation by typing "R". For example, the following shows a successful re-negotiation against a FortiGate unit configured with a VIP for 192.168.2.100:443:

```
$ openssl s_client -connect 192.168.2.100:443

IP, TCP, and UDP load balancing

You can load balance all IP, TCP or UDP sessions accepted by the security policy that includes a load balancing virtual server with the type set to IP, TCP, or UDP. Traffic with destination IP and port that matches the virtual server IP and port is load balanced. For these protocol-level load balancing virtual servers you can select a load balance method and add real servers and health checking. However, you can't configure persistence, HTTP multiplexing and SSL offloading.

Example HTTP load balancing to three real web servers

In this example, a virtual web server with IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the **First Alive** load balancing method. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

Virtual server configuration example

GUI configuration

Use the following procedures to configure this load balancing setup from the GUI.

To add an HTTP health check monitor

In this example, the HTTP health check monitor includes the **URL** “/index.html” and the **Matched Phrase** “Fortinet products”.

1. Go to **Policy & Objects > Health Check**.
2. Select **Create New**.
3. Add an HTTP health check monitor that sends get requests to `http://<real_server_IP_address>/index.html` and searches the returned web page for the phrase “Fortinet products”.

Name	HTTP_health_chk_1
Type	HTTP
Port	80
URL	/index.html
Matched Content	Fortinet products

Interval	10 seconds
Timeout	2 seconds
Retry	3

4. Select **OK**.

To add the HTTP virtual server and the real servers

1. Go to **Policy & Objects > Virtual Servers**.
2. Select **Create New**.
3. Add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

Name	Load_Bal_VS1
Type	HTTP
Interface	wan1
Virtual Server IP	192.168.37.4 The public IP address of the web server. The virtual server IP address is usually a static IP address obtained from your ISP for your web server. This address must be a unique IP address that is not used by another host and cannot be the same as the IP address of the external interface the virtual IP will be using. However, the external IP address must be routed to the selected interface. The virtual IP address and the external IP address can be on different subnets. When you add the virtual IP, the external interface responds to ARP requests for the external IP address.
Virtual Server Port	80
Load Balance Method	First Alive
Persistence	HTTP cookie
Health Check	HTTP_health_chk_1
HTTP Multiplexing	Turn on. The FortiGate unit multiplexes multiple client into a few connections between the FortiGate unit and each real HTTP server. This can improve performance by reducing server overhead associated with establishing multiple connections.
Preserve Client IP	Turn on. The FortiGate unit preserves the IP address of the client in the <code>X-Forwarded-For</code> HTTP header.

4. Add three real servers to the virtual server. Each real server must include the IP address of a real server on the internal network.

Configuration for the first real server.

IP Address	10.10.10.42
Port	80
Max Connections	0
	Setting Max Connections to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses First Alive load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the Max Connections is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.
Mode	Active

Configuration for the second real server.

IP Address	10.10.10.43
Port	80
Max Connections	0
Mode	Active

Configuration for the third real server.

IP Address	10.10.10.44
Port	80
Max Connections	0
Mode	Active

To add the virtual server to a security policy

Add a wan1 to dmz1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Configure the security policy:

Name	Add a name for the policy.
Incoming Interface	wan1

Outgoing Interface	dmz1
Source	all (or a more specific address)
Destination	Load_Bal_VS1
Schedule	always
Service	HTTP
Action	ACCEPT
NAT	Select this option and select Use Destination Interface Address .
Log Allowed Traffic	Select to log virtual server traffic

4. Select other security policy options as required.
5. Select **OK**.

CLI configuration

Use the following procedure to configure this load balancing setup from the CLI.

To configure HTTP load balancing

1. Use the following command to add an HTTP health check monitor that sends get requests to `http://<real_server_IP_address>/index.html` and searches the returned web page for the phrase "Fortinet products".

```
config firewall ldb-monitor
  edit HTTP_health_chk_1
    set type http
    set port 80
    set http-get /index.html
    set http-match "Fortinet products"
    set interval 10
    set timeout 2
    set retry 3
  end
```

2. Use the following command to add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

```
config firewall vip
  edit Load-Bal_VS1
    set type server-load-balance
    set server-type http
    set ldb-method first-alive
    set http-multiplex enable
    set http-ip-header enable
    set extip 192.168.37.4
    set extintf wan1
    set extport 80
    set persistence http-cookie
    set monitor HTTP_health_chk_1
    config realservers
      edit 1
        set ip 10.10.10.42
        set port 80
      end
    end
```

```

        next
        edit 2
            set ip 10.10.10.43
            set port 80
        next
        edit 3
            set ip 10.10.10.44
            set port 80
        end
    end
end

```

3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```

config firewall policy
    edit 0
        set name <policy-name>
        set srcintf wan1
        set srcaddr all
        set dstintf dmz1
        set dstaddr Load-Bal_VS1
        set action accept
        set schedule always
        set service ALL
        set nat enable
    end

```

Configure other security policy settings as required.

Example Basic IP load balancing configuration

This example shows how to add a server load balancing virtual IP that load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3. The default weight is 1 and does not have to be changed for the first real server.

```

config firewall vip
    edit All_Load_Balance
        set type server-load-balance
        set server-type ip
        set extintf port2
        set extip 192.168.20.20
        set ldb-method weighted
        config realservers
            edit 1
                set ip 10.10.10.1
            next
            edit 2
                set ip 10.10.10.2
                set weight 2
            next
            edit 3
                set ip 10.10.10.3
                set weight 3
            end
        end
    end

```

end

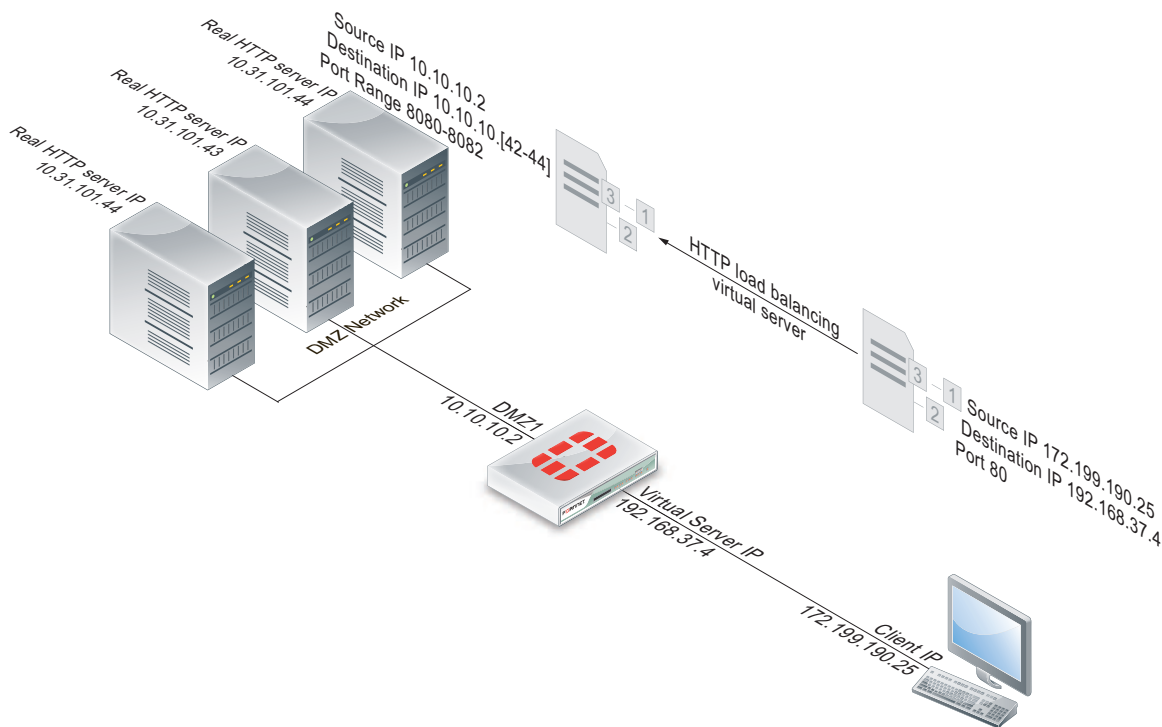

Example Adding a server load balance port forwarding virtual IP

In this example, a virtual web server with IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the **First Alive** load balancing method.

Each real server accepts HTTP connections on a different port number. The first real server accepts connections on port 8080, the second on port 8081, and the third on 8082. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

Server load balance virtual IP port forwarding

To complete this configuration, all of the steps would be the same as in [Example Adding a server load balance port forwarding virtual IP on page 2635](#) except for configuring the real servers.

To add the real servers to the virtual server

Use the following steps to add three real servers to the virtual server Load_Bal_VS1. These real servers cause the FortiGate unit to forward HTTP packets to the three real servers on ports 8080, 8081, and 8082.

1. Go to **Policy & Objects > Virtual Servers** and edit the **Load_Bal_VS1** virtual server.
2. Select **Create New**.
3. Add the following three real servers. Each real server must include the IP address of a real server on the internal network and have a different port number.

Configuration for the first real server.

IP Address	10.10.10.42
Port	8080
Max Connections	0
Mode	Active

Configuration for the second real server.

IP	10.10.10.43
Port	8081
Max Connections	0
Mode	Active

Configuration for the third real server.

IP	10.10.10.44
Port	8082
Max Connections	0
Mode	Active

Example Weighted load balancing configuration

This example shows how to using firewall load balancing to load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3.

This configuration does not include a health check monitor.

GUI configuration

Use the following procedures to configure this load balancing setup from the FortiGate GUI.

To add the HTTP virtual server

1. Go to **Policy & Objects > Virtual Servers**.
2. Select **Create New**.
3. Add an IP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate port2 interface is connected to the Internet.

Name	HTTP_weghted_LB
Type	IP
Interface	port2
Virtual Server IP	192.168.20.20
Load Balance Method	Weighted

All other virtual server settings are not required or cannot be changed.

4. Under **Real Servers** select **Create New**.
5. Add three real servers. Because the **Load Balancing Method** is **Weighted**, each real server includes a weight. Servers with a higher weight receive a more sessions.

Configuration for the first real server.

IP Address	10.10.10.1
Weight	1
Max Connections	0
	Setting Max Connections to 0 means the FortiGate unit does not limit the number of connections to the real server.
Mode	Active

Configuration for the second real server.

IP Address	10.10.10.2
Weight	2
Max Connections	0
Mode	Active

Configuration for the third real server.

IP Address	10.10.10.3
Weight	3
Max Connections	0
Mode	Active

To add the virtual server to a security policy

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Configure the security policy:

Name	Policy name
Incoming Interface	port2
Outgoing Interface	port1
Source	all (or a more specific address)
Destination	HTTP_weghted_LB
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Select this option and select Use Destination Interface Address .

4. Select other security policy options as required.
5. Select **OK**.

CLI configuration

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`. The default weight is 1 and does not have to be changed for the first real server.

Use the following command to add the virtual server and the three weighted real servers.

```
config firewall vip
  edit HTTP_weghted_LB
    set type server-load-balance
    set server-type ip
    set extintf port2
    set extip 192.168.20.20
    set ldb-method weighted
    config realservers
      edit 1
        set ip 10.10.10.1
      next
      edit 2
        set ip 10.10.10.2
        set weight 2
      next
      edit 3
        set ip 10.10.10.3
```

```

        set weight 3
    end
end

```

Example HTTP and HTTPS persistence configuration

This example shows how to add a virtual server named **HTTP_Load_Balance** that load balances HTTP traffic using port 80 and a second virtual server named **HTTPS_Load_Balance** that load balances HTTPS traffic using port 443. The Internet is connected to port2 and the virtual IP address of the virtual server is 192.168.20.20. Both server load balancing virtual IPs load balance sessions to the same three real servers with IP addresses 10.10.10.2, 10.10.10.2, and 10.10.10.3. The real servers provide HTTP and HTTPS services.

For both virtual servers, persistence is set to **HTTP Cookie** to enable HTTP cookie persistence.

To add the HTTP and HTTPS virtual servers

1. Go to **Policy & Objects > Virtual Servers**.
2. Add the HTTP virtual server that includes HTTP Cookie persistence.

Name	HTTP_Load_Balance
Type	HTTP
Interface	port2
Virtual Server IP	192.168.20.20
Virtual Server Port	80 In this example the virtual server uses port 8080 for HTTP sessions instead of port 80.
Load Balance Method	Static
Persistence	HTTP cookie

3. Under **Real Servers** select **Create New**.
4. Add three real servers.

Configuration for the first real server.

IP Address	10.10.10.1
Port	80
Max Connections	0
Mode	Active

Configuration for the second real server.

IP Address	10.10.10.2
Port	80
Maximum Connections	0
Mode	Active

Configuration for the third real server.

IP Address	10.10.10.3
Port	80
Max Connections	0
Mode	Active

5. Select **OK**.
6. Select **Create New** to add the HTTPS virtual server that also includes HTTP Cookie persistence.

Name	HTTPS_Load_Balance
Type	HTTPS
Interface	port2
Virtual Server IP	192.168.20.20
Virtual Server Port	443
Load Balance Method	Static
Persistence	HTTP cookie

7. Under **Real Servers** select **Create New**
8. Add three real servers.

Configuration for the first real server.

IP Address	10.10.10.1
Port	443
Max Connections	0
Mode	Active

Configuration for the second real server.

IP Address	10.10.10.2
Port	443

Max Connections	0
Mode	Active

Configuration for the third real server.

IP Address	10.10.10.3
Port	443
Max Connections	0
Mode	Active

To add the virtual servers to security policies

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Configure the HTTP security policy:

Name	Policy name.
Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	HTTP_Load_Balance
Schedule	always
Service	HTTP
Action	ACCEPT
NAT	Select this option and select Use Destination Interface Address .

4. Select other security policy options as required.
5. Select **OK**.
6. Select **Create New**.
7. Configure the HTTP security policy:

Name	Policy name.
Incoming Interface	port2
Outgoing Interface	port1

Source	all
Destination	HTTPS_Load_Balance
Schedule	always
Service	HTTPS
Action	ACCEPT
NAT	Select this option and select Use Destination Interface Address .

8. Select other security policy options as required.

9. Select **OK**.

CLI configuration: adding persistence for a specific domain

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`.

For the CLI configuration, both virtual servers include setting `http-cookie-domain` to `.example.org` because HTTP cookie persistence is just required for the `example.org` domain.

First, the configuration for the HTTP virtual IP:

```
config firewall vip
  edit HTTP_Load_Balance
    set type server-load-balance
    set server-type http
    set extport 8080
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
    config realservers
      edit 1
        set ip 10.10.10.1
      next
      edit 2
        set ip 10.10.10.2
      next
      edit 3
        set ip 10.10.10.3
    end
  end
```

Second, the configuration for the HTTPS virtual IP. In this configuration you don't have to set `extport` to 443 because `extport` is automatically set to 443 when `server-type` is set to `https`.

```
config firewall vip
  edit HTTPS_Load_Balance
    set type server-load-balance
    set server-type https
    set extport 443
    set extintf port2
    set extip 192.168.20.20
    set persistence http-cookie
    set http-cookie-domain .example.org
```

```
config realservers
  edit 1
    set ip 10.10.10.1
  next
  edit 2
    set ip 10.10.10.2
  next
  edit 3
    set ip 10.10.10.3
  end
end
```

Chapter 23 - SSL VPN

The following chapters are included in this document:

[Overview](#) provides useful general information about VPN and SSL, how the FortiGate unit implements them, and gives guidance on how to choose between SSL and IPsec.

[Basic configuration](#) explains how to configure the FortiGate unit and the web portal. Along with these configuration details, this chapter also explains how to grant unique access permissions, how to configure the SSL encryption key algorithm, and describes the SSL VPN OS Patch Check feature that allows a client with a specific OS patch to access SSL VPN services.

[The SSL VPN client](#) provides an overview of the FortiClient software required for tunnel mode, where to obtain the software, how to install it, and the configuration information required for remote users to connect to the internal network.

[The SSL VPN web portal](#) provides an overview of the SSL VPN web portal, with explanations of how to use and configure the web portal features.

[Setup examples](#) explores several configuration scenarios with step-by-step instructions. While the information provided is enough to set up the described SSL VPN configurations, these scenarios are not the only possible SSL VPN setups.

[Troubleshooting](#) provides some general maintenance and troubleshooting procedures for SSL VPNs.

What's new in FortiOS 6.0.1

The following list contains new SSL VPN features added in FortiOS 6.0.1. Click on a link to navigate to that section for further information.

- ["Automatic bookmarks for SSO credentials" on page 2694](#)
- [" HTTP header information" on page 2712](#)

Overview

As organizations have grown and become more complex, secure remote access to network resources has become critical for day-to-day operations. In addition, businesses are expected to provide clients with efficient, convenient services including knowledge bases and customer portals. Employees traveling across the country or around the world require timely and comprehensive access to network resources. As a result of the growing need for providing remote/mobile clients with easy, cost-effective and secure access to a multitude of resources, the concept of a Virtual Private Network (VPN) was developed.

SSL VPNs establish connectivity using SSL, which functions at Levels 4 - 5 (Transport and Session layers). Information is encapsulated at Levels 6 - 7 (Presentation and Application layers), and SSL VPNs communicate at the highest levels in the OSI model. SSL is not strictly a Virtual Private Network (VPN) technology that allows clients to connect to remote networks in a secure way. A VPN is a secure logical network created from physically separate networks. VPNs use encryption and other security methods to ensure that only authorized users can access the network. VPNs also ensure that the data transmitted between computers cannot be intercepted by unauthorized users. When data is encoded and transmitted over the Internet, the data is said to be sent through a "VPN tunnel". A VPN tunnel is a non-application oriented tunnel that allows the users and networks to exchange a wide range of traffic regardless of application or protocol.

The advantages of a VPN over an actual physical private network are two-fold. Rather than utilizing expensive leased lines or other infrastructure, you use the relatively inexpensive, high-bandwidth Internet. Perhaps more important though is the universal availability of the Internet. In most areas, access to the Internet is readily obtainable without any special arrangements or long wait times.

SSL (Secure Sockets Layer) as HTTPS is supported by most web browsers for exchanging sensitive information securely between a web server and a client. SSL establishes an encrypted link, ensuring that all data passed between the web server and the browser remains private and secure. SSL protection is initiated automatically when a user (client) connects to a web server that is SSL-enabled. Once the successful connection is established, the browser encrypts all the information before it leaves the computer. When the information reaches its destination, it is decrypted using a secret (private) key. Any data sent back is first encrypted, and is decrypted when it reaches the client.

FortiOS supports the SSL and TLS versions defined below:

SSL and TLS version support table

Version	RFC
SSL 2.0	RFC 6176
SSL 3.0	RFC 6101
TLS 1.0	RFC 2246
TLS 1.1	RFC 4346
TLS 1.2	RFC 5246

SSL VPN modes of operation

When a remote client connects to the FortiGate unit, the FortiGate unit authenticates the user based on username, password, and authentication domain. A successful login determines the access rights of remote users according to user group. The user group settings specify whether the connection will operate in web-only mode or tunnel mode.

Web-only mode

Web-only mode provides remote users with a fast and efficient way to access server applications from any thin client computer equipped with a web browser. Web-only mode offers true clientless network access using any web browser that has built-in SSL encryption and the Sun Java Runtime Environment (note that there is no minimum Java/JRE version requirement—any version of Java/JRE currently supported by the supplier of the Java/JRE for the operating system should work).

Support for SSL VPN web-only mode is built into FortiOS. The feature comprises of an SSL daemon running on the FortiGate unit, and a web portal, which provides users with access to network services and resources including HTTP/HTTPS, Telnet, FTP, SMB/CIFS, VNC, RDP, and SSH.

In web-only mode, the FortiGate unit acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group. After successful authentication, the FortiGate unit redirects the web browser to the web portal home page and the user can access the server applications behind the FortiGate unit.

When the FortiGate unit provides services in web-only mode, a secure connection between the remote client and the FortiGate unit is established through the SSL VPN security in the FortiGate unit and the SSL security in the web browser. After the connection has been established, the FortiGate unit provides access to selected services and network resources through a web portal.

FortiGate SSL VPN web portals have a 1- or 2-column page layout and portal functionality is provided through small applets called widgets. Widget windows can be moved or minimized. The controls within each widget depend on its function. There are predefined web portals and the administrator can create additional portals.

Configuring the FortiGate unit involves selecting the appropriate web portal configuration in the user group settings. These configuration settings determine which server applications can be accessed. SSL encryption is used to ensure traffic confidentiality.

The following table lists the operating systems and web browsers supported by SSL VPN web-only mode.

VPN Web-only Mode, supported operating systems and web browsers

Operating System	Web Browser
Microsoft Windows 7 SP1 (32-bit/64-bit)	<ul style="list-style-type: none">• Microsoft Internet Explorer version 11• Mozilla Firefox version 46
Microsoft Windows 8/8.1 (32-bit/64-bit)	
Microsoft Windows 10 (32-bit/64-bit)	

Operating System	Web Browser
Mac OS 10.11	<ul style="list-style-type: none"> • Safari version 9 • Chrome version 56
Linux CentOS version 6.5	<ul style="list-style-type: none"> • Mozilla Firefox version 46

Other operating systems and web browsers may function correctly, but are not supported by Fortinet.

Tunnel mode

In Tunnel mode, remote clients connect to a FortiGate unit that acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group.

The SSL VPN client encrypts all traffic from the remote client computer and sends it to the FortiGate unit through an SSL VPN tunnel over the HTTPS link between the user and the FortiGate unit. Another option is split tunneling, which ensures that only the traffic for the private network is sent to the SSL VPN gateway. Internet traffic is sent through the usual unencrypted route. This conserves bandwidth and alleviates bottlenecks.

When the user initiates a VPN connection with the FortiGate unit through the SSL VPN client, the FortiGate unit establishes a tunnel with the client and assigns the client a virtual IP address from a range of reserved addresses. The client uses the assigned IP address as its source address for the duration of the connection. After the tunnel has been established, the user can access the network behind the FortiGate unit.

Port forwarding mode

While tunnel mode provides a Layer 3 tunnel that users can run any application over, the user needs to install the tunnel client, and have the required administrative rights to do so. In some situations, this may not be desirable, yet the simple web mode does not provide enough flexibility for application support (for example, if you wish to use an email client that communicates with a POP3 server). The port forward mode, or proxy mode, provides this middle ground between web mode and tunnel mode.

SSL VPN port forwarding listens on local ports on the user's computer. When it receives data from a client application, the port forward module encrypts and sends the data to the FortiGate unit, which then forwards the traffic to the application server.

The port forward module is implemented with a Java applet, which is downloaded and runs on the user's computer. The applet provides the up-to-date status information such as addressing and bytes sent and received.

On the user end, the user logs into the FortiGate SSL VPN portal, and selects a port forward bookmark configured for a specific application. The bookmark defines the server address and port as well as which port to listen to on the user's computer.

The user must configure the application on the PC to point to the local proxy instead of the application server. For information on this configuration change, see the application documentation.

This mode only supports client/server applications that are using a static TCP port. It will not support client/server applications using dynamic ports or traffic over UDP.

Application support

With Citrix application servers, the server downloads an ICA configuration file to the user's PC. The client application uses this information to connect to the Citrix server. The FortiGate unit will read this file and append a SOCKS entry to set the SOCKS proxy to 'localhost'. The Citrix client will then be able to connect to the SSL VPN port forward module to provide the connection. When configuring the port forwarding module, a selection is available for Citrix servers.

For Windows Remote Desktop Connections, when selecting the RDP option, the tunnel will launch the RDP client and connect to the local loopback address after the port forward module has been initiated.

Note that the RDP/VNC web portals are **not** supported for the following platforms:

Platform	Model
FortiGate	80D, 92D, 200D, 200D-POE, 240D, 240D-POE, 600C, 800C, 1000C, 3240C, 3600C, and 5001C
FortiGate-Rugged	90D
FortiWiFi	92D

Antivirus and firewall host compatibility

The following tables list the antivirus and firewall client software packages that are supported in FortiOS.

Supported Windows XP antivirus and firewall software

Product supported	Antivirus	Firewall
Symantec Endpoint Protection V11	•	•
Kaspersky Antivirus 2009	•	
McAfee Security Center v8.1	•	•
Trend Micro Internet Security Pro	•	•
F-Secure Internet Security 2009	•	•

Supported Windows 7 32-bit and 64-bit antivirus and firewall software

Product supported	Antivirus	Firewall
CA Internet Security 2011	•	•
AVG Internet Security 2011		
F-Secure Internet Security 2011	•	•

Product supported	Antivirus	Firewall
Kaspersky Internet Security 2011	•	•
McAfee Internet Security 2011	•	•
Norton 360™ Version 4.0	•	•
Norton™ Internet Security 2011	•	•
Panda Internet Security 2011	•	•
Sophos Security Suite	•	•
Trend Micro Titanium Internet Security	•	•
ZoneAlarm Security Suite	•	•
Symantec Endpoint Protection Small Business Edition 12.0	•	•

SSL VPN conserve mode

FortiGate units perform all security profile processing in physical RAM. Since each model has a limited amount of memory, Kernel conserve mode is activated when the remaining free memory is nearly exhausted or the AV proxy has reached the maximum number of sessions it can service.

SSL VPN also has its own conserve mode. The FortiGate enters the SSL VPN conserve mode before the Kernel conserve mode in an attempt to prevent the Kernel conserve mode from triggering. During the SSL VPN conserve mode, no new SSL connections are allowed. It starts when free memory is <25% of the total memory (when the memory on the FortiGate is less than 512Mb) or <10% of the total memory (when the FortiGate has more than 512Mb built in).

To determine if the FortiGate has entered SSL VPN conserve mode - CLI

Run the following command in the CLI Console:

```
diagnose vpn ssl statistics
```

Result (showing conserve mode state in red):

```
SSLVPN statistics:
-----
Memory unit:                1
System total memory:        2118737920
System free memory:         218537984
SSLVPN memory margin:       314572800
SSLVPN state:                conserve

Max number of users:        2
Max number of tunnels:      0
Max number of connections:  13
```

```
Current number of users:      1
Current number of tunnels:    0
Current number of connections: 1
```

Traveling and security

Because SSL VPN provides a means for “on-the-go” users to dial in to the network while away from the office, you need to ensure that wherever and however they choose to dial in is secure, and not potentially compromising the corporate network.

Host check

To reinforce security, you can enable a host integrity checker to scan the remote client. The integrity checker probes the remote client computer to verify that it is safe before access is granted. Security attributes recorded on the client computer (for example, in the Windows registry, in specific files, or held in memory due to running processes) are examined and uploaded to the FortiGate unit. For more information, see [Host check on page 2674](#).

Host Check is applicable for both SSL VPN Web Mode and SSL VPN Tunnel mode.

SSL VPN and IPv6

FortiOS supports SSL VPN with IPv6 addressing, and is available for all the java applets (Telnet, VNC, RDP, and so on). IPv6 configurations for security policies and addressing include:

- Policy matching for IPv6 addresses
- Support for DNS resolving in SSL VPN
- Support IPv6 for ping
- FTP applications
- SMB

In essentially any of the following instructions, replace **IPv4** with **IPv6** to achieve the same desired results, but for IPv6 addresses and configurations.

Basic configuration

Configuring SSL VPN involves a number of configurations within FortiOS that you need to complete to make it all come together. This chapter describes the components required, and how and where to configure them to set up the FortiGate unit as an SSL VPN server. The configurations and steps are high level, to show you the procedures needed, and where to locate the options in FortiOS. For real-world examples, see [Setup examples on page 2699](#).

There are three or four key steps to configuring an SSL VPN tunnel. The first three in the points below are mandatory, while the others are optional. This chapter outlines these key steps as well as additional configurations for tighter security and monitoring.

The key steps are:

- Create user accounts and user groups for the remote clients.
([User accounts and groups on page 2651](#))
- Create a web portal to define user access to network resources.
([Configuring SSL VPN web portals on page 2656](#))
- Configure the security policies.
([Configuring security policies on page 2665](#))
- For tunnel-mode operation, add routing to ensure that client tunnel-mode packets reach the SSL VPN interface.
([Routing in tunnel mode on page 2672](#))
- Setup logging of SSL VPN activities.
([SSL VPN logs on page 2680](#))

This section contains the following information:

User accounts and groups

The first step for an SSL VPN tunnel is to add the users and user groups that will access the tunnel. You may already have users defined for other authentication-based security policies.

The user group is associated with the web portal that the user sees after logging in. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

To create a user account:

- In the web-based manager, go to **User & Device > User Definition**, and select **Create New**.
- In the CLI, use the commands in `config user local`.

All users accessing the SSL tunnel must be in a firewall user group. User names can be up to 64 characters long.

To create user groups:

- In the web-based manager, go to **User & Device > User Groups** and select **Create New**.
- In the CLI, use the commands in `config user group`.

Guest group and SSO group have been removed from `config user group` and `config vpn ssl web user-group-bookmark`.

Authentication

Remote users must be authenticated before they can request services and/or access network resources through the web portal. The authentication process can use a password defined on the FortiGate unit or optionally use established external authentication mechanisms such as RADIUS or LDAP.

To authenticate users, you can use a plain text password on the local FortiGate unit, forward authentication requests to an external RADIUS, LDAP or TACACS+ server, or utilize PKI certificates.

For information about how to create RADIUS, LDAP, TACACS+ or PKI user accounts and certificates, see the [Authentication Guide](#).

FortiOS supports LDAP password renewal notification and updates through SSL VPN. Configuration is enabled using the CLI commands:

```
config user ldap
  edit <username>
    set server <domain>
    set password-expiry-warning enable
    set password-renewal enable
  next
end
```

For more information, see the [Authentication Guide](#).

MAC host check

When a remote client attempts to log in to the portal, you can have the FortiGate unit check against the client's MAC address to ensure that only a specific computer or device is connecting to the tunnel. This can ensure better security should a password be compromised.

MAC addresses can be tied to specific portals and can be either the entire MAC address or a subset of the address. MAC host checking is configured in the CLI using the following commands:

```
conf vpn ssl web portal
  edit portal
    set mac-addr-check enable
    set mac-addr-action allow
    config mac-addr-check-rule
      edit "rule1"
        set mac-addr-list 01:01:01:01:01:01 08:00:27:d4:06:5d
        set mac-addr-mask 48
      end
    end
  end
```

IP addresses for users

After the FortiGate unit authenticates a request for a tunnel-mode connection, the FortiGate unit assigns the SSL VPN client an IP address for the session. The address is assigned from an IP Pool, which is a firewall address defining an IP address range.

Take care to prevent overlapping IP addresses. Do not assign to clients any IP addresses that are already in use on the private network. As a precaution, consider assigning IP addresses from a network that is not commonly used (for example, 10.254.254.0/24).

To set tunnel-mode client IP address range - web-based manager:

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Enter an **Name**, for example, `SSL_VPN_tunnel_range`.
3. Select a **Type** of **IP Range**.
4. In the **Subnet/IP Range** field, enter the starting and ending IP addresses that you want to assign to SSL VPN clients, for example `10.254.254.[80-100]`.
5. In **Interface**, select **Any**.
6. Select **OK**.

To set tunnel-mode client IP address range - CLI:

If your SSL VPN tunnel range is for example 10.254.254.80 - 10.254.254.100, you could enter

```
config firewall address
  edit SSL_tunnel_users
    set type iprange
    set end-ip 10.254.254.100
    set start-ip 10.254.254.80
  end
```

Authentication of remote users

When remote users connect to the SSL VPN tunnel, they must perform authentication before being able to use the internal network resources. This can be as simple as assigning users with their own passwords, connecting to an LDAP server or using more secure options. FortiOS provides a number of options for authentication as well as security option for those connected users.

The web portal can include bookmarks to connect to internal network resources. A web (HTTP/HTTPS) bookmark can include login credentials so that the FortiGate unit automatically logs the user into the website. This means that the user logs into the SSL VPN and then does not have to enter any more credentials to visit preconfigured web sites.

Both the administrator and the end user can configure bookmarks, including SSO bookmarks. To add bookmarks as a web portal user, see [Using the Bookmarks widget on page 2692](#).

Setting the client authentication timeout

The client authentication timeout controls how long an authenticated user will remain connected. When this time expires, the system forces the remote client to authenticate again. As with the idle timeout, a shorter period of

time is more secure. The default value is 28800 seconds (8 hours). You can only modify this timeout value in the CLI.

For example, to change the authentication timeout to 18 000 seconds, enter the following commands in the CLI:

```
config vpn ssl settings
    set auth-timeout 18000
end
```

You can also set the idle timeout for the client, to define how long the user does not access the remote resources before they are logged out.

Additional timeout settings

SSL VPN timeout settings are also available to counter 'Slowloris' and 'R-U-Dead-Yet' vulnerabilities that allow remote attackers to cause a denial of service via partial HTTP requests.

The FortiGate solution involves two attributes (`http-request-header-timeout` and `http-request-body-timeout`).

CLI syntax

```
config vpn ssl settings
    set http-request-header-timeout [1-60] (seconds)
    set http-request-body-timeout [1-60] (seconds)
end
```

Allow one-time login per user

You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again.

To allow one-time login per user - web-based manager:

Go to **VPN > SSL-VPN Portals**, select a portal, and enable **Limit Users to One SSL-VPN Connection at a Time**. It is disabled by default.

To allow one-time login per user - CLI:

```
config vpn ssl web portal
    edit <portal_name>
        set limit-user-logins enable
    end
```

Strong authentication with security certificates

The FortiGate unit supports strong (two-factor) authentication through X.509 security certificates (version 1 or 3). The FortiGate unit can require clients to authenticate using a certificate, and the client can require the FortiGate unit to authenticate using a certificate.

For information about obtaining and installing certificates, see the [Authentication Guide](#).

You can select the **Require Client Certificate** option so that clients must authenticate using certificates. The client browser must have a local certificate installed, and the FortiGate unit must have the corresponding CA certificate installed.

When the remote client initiates a connection, the FortiGate unit prompts the client browser for its client-side certificate as part of the authentication process.

To require client authentication by security certificates - web-based manager:

1. Go to **VPN > SSL-VPN Settings**.
2. Select **Require Client Certificate**.
3. Select **Apply**.

To require client authentication by security certificates - CLI:

```
config vpn ssl settings
    set reqclientcert enable
end
```

If your SSL VPN clients require strong authentication, the FortiGate unit must offer a CA certificate that the client browser has installed.

In the FortiGate unit SSL VPN settings, you can select which certificate the FortiGate offers to authenticate itself. By default, the FortiGate unit offers its factory installed (Fortinet_CA_SSLProxy) certificate from Fortinet to remote clients when they connect. If you leave the default setting, a warning appears that recommends you purchase a certificate for your domain and upload it for use.

To enable FortiGate unit authentication by certificate - web-based manager:

1. Go to **VPN > SSL-VPN Settings**.
2. From the **Server Certificate** list, select the certificate that the FortiGate unit uses to identify itself to SSL VPN clients.
3. Select **Apply**.

To enable FortiGate unit authentication by certificate - CLI:

For example, to use the `example_cert` certificate

```
config vpn ssl settings
    set servercert example_cert
end
```

FortiOS will check the server certificate to verify that the certificate is valid. Only valid server certificates should be used.

NSA Suite B cryptography support

FortiOS supports the use of ECDSA Local Certificates for SSL VPN Suite B. The National Security Agency (NSA) developed Suite B algorithms in 2005 to serve as a cryptographic base for both classified and unclassified information at an interoperable level.

FortiOS allows you to import, generate, and use ECDSA certificates defined by the Suite B cryptography set. To generate ECDSA certificates, use the following command in the CLI:

```
exec vpn certificate local generate ec <certificate-name_str> <elliptic-curve-name>  
    <subject_str> [<optional_information>]
```

Configuring SSL VPN web portals

The SSL VPN portal enables remote users to access internal network resources through a secure channel using a web browser. FortiGate administrators can configure login privileges for system users as well as the network resources that are available to the users.

FortiOS supports LDAP password renewal notification and updates through SSL VPN. Configuration is enabled using the CLI commands:

```
config user ldap  
    edit <username>  
        set server <domain>  
        set password-expiry-warning enable  
        set password-renewal enable  
    next  
end
```

For more information, see the [Authentication Guide](#).

This step in the configuration of the SSL VPN tunnel sets up the infrastructure; the addressing, encryption, and certificates needed to make the initial connection to the FortiGate unit. This step is also where you configure what the remote user sees with a successful connection. The portal view defines the resources available to the remote users and the functionality they have on the network.

SSL connection configuration

To configure the basic SSL VPN settings for encryption and login options, go to **VPN > SSL-VPN Settings**.

Listen on Interface(s)	Define the interface which the FortiGate will use to listen for SSL VPN tunnel requests. This is generally your external interface.
Listen on Port	Enter the port number for HTTPS access.

Redirect port 80 to this login port

Enable to redirect the admin HTTP port to the admin HTTPS port.

There are two likely scenarios for this:

- SSL VPN is not in use, in which case the admin GUI runs on port 443 or 10443, and port 80 is redirected.
- SSL VPN runs on port 443, in which case port 80 is redirected to 443 and the admin port runs on 10443.

If the administrator chooses to run SSL VPN on port 80, the redirect option is invalid.

This can also be configured in the CLI as shown below (note that HTTPS-redirect is disabled by default):

Syntax:

```
config vpn ssl settings
    set https-redirect [enable | disable]
end
```

Restrict Access

Restrict accessibility to either **Allow access from any host** or to **Limit access to specific hosts** as desired. If selecting the latter, you must specify the hosts.

Idle Logout

Type the period of time (in seconds) that the connection can remain inactive before the user must log in again. The range is from 10 to 28800 seconds. Setting the value to 0 will disable the idle connection timeout. This setting applies to the SSL VPN session. The interface does not time out when web application sessions or tunnels are up.

Server Certificate

Select the signed server certificate to use for authentication. If you leave the default setting (Fortinet_CA_SSLProxy), the FortiGate unit offers its built-in certificate from Fortinet to remote clients when they connect. A warning appears that recommends you purchase a certificate for your domain and upload it for use.

Require Client Certificate

Select to use group certificates for authenticating remote clients. When the remote client initiates a connection, the FortiGate unit prompts the client for its client-side certificate as part of the authentication process.

For information on using PKI to provide client certificate authentication, see the [Authentication Guide](#).

Address Range

Select **Automatically assign addresses** or **Specify custom IP ranges**. The latter will allow you to select the range or subnet firewall addresses that represent IP address ranges reserved for tunnel-mode SSL VPN clients.

DNS Server

If you select **Specify**, you may enter up to two DNS servers (IPv4 or IPv6) to be provided for the use of clients.

Note: It is possible to implement a unique DNS suffix per SSL VPN portal using the CLI. Each suffix setting for each specific portal will override the `dns-suffix` setting under `config vpn ssl settings`. This is a CLI-only option, using the following syntax:

```
config vpn ssl web portal
edit <example>
set dns-suffix <string>
end
```

Specify WINS Servers

Enable to access options for entering up to two WINS servers (IPv4 or IPv6) to be provided for the use of clients.

Allow Endpoint Registration

Select so that FortiClient registers with the FortiGate unit when connecting. If you configured a registration key by going to **System > Config > Advanced**, the remote user is prompted to enter the key. This only occurs on the first connection to the FortiGate unit.

Portal configuration

The portal configuration determines what the remote user sees when they log in to the portal. Both the system administrator and the user have the ability to customize the SSL VPN portal.

To view the portals settings page, go to **VPN > SSL-VPN Portals**.

There are three pre-defined default portal configurations available:

- *full-access*
- *tunnel-access*
- *web-access*

Each portal type includes similar configuration options. Select between the different portals by double-clicking one of the default portals in the list. You can also create a custom portal by selecting the **Create New** option at the top.

Portal Setting	Description
Name	The name for the portal.
Limit Users to One SSL-VPN Connection at a Time	You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again. This option is disabled by default.
Tunnel Mode	These settings determine how tunnel mode clients are assigned IPv4 addresses.

Portal Setting	Description
Enable Split Tunneling	<p>Select so that the VPN carries only the traffic for the networks behind the FortiGate unit. The user's other traffic follows its normal route.</p> <p>If you enable split tunneling, you are required to set the Routing Address, which is the address that your corporate network is using. Traffic intended for the Routing Address will not be split from the tunnel.</p>
Source IP Pools	Select an IP Pool for users to acquire an IP address when connecting to the portal. There is always a default pool available if you do not create your own.
Tunnel Mode Client Options	<p>These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default.</p> <ul style="list-style-type: none"> • Allow client to save password - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN. • Allow client to connect automatically - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel. • Allow client to keep connections alive - When enabled, if the user selects this option, the FortiClient should try to reconnect once it detects the VPN connection is down unexpectedly (not manually disconnected by user).
Enable Web Mode	Select to enable web mode access.
Portal Message	This is a text header that appears on the top of the web portal.
Theme	Select a color styling specifically for the web portal.
Show Session Information	The Show Session Information widget displays the login name of the user, the amount of time the user has been logged in and the inbound and outbound traffic statistics.
Show Connection Launcher	Displays the Connection Launcher widget in the web portal.
Show Login History	Select to include user login history on the web portal.

Portal Setting	Description
User Bookmarks	Enable to allow users to add their own bookmarks in the web portal.
Predefined Bookmarks	Select to include bookmarks on the web portal. Bookmarks are used as links to internal network resources. When a bookmark is selected from a bookmark list, a pop-up window appears with the web page. Telnet, VNC, and RDP require a browser plugin. FTP and Samba replace the bookmarks page with an HTML file-browser.

Tunnel Mode Client Options logic

The FortiGate will check the logic of Tunnel mode VPN client options.

If `auto-connect` or `keep-alive` is enabled, the following warning message will be shown: *'save-password should be enabled if either auto-connect or keep-alive is enabled.'*

At the end of editing the portal, if either `auto-connect` or `keep-alive` is enabled and `save-password` is not enabled, the following message will be shown, and adding or editing the portal is not permitted: *'save-password should be enabled as either auto-connect or keep-alive is enabled.'*

Options to allow firewall address to be used in routing table for SSL VPN

If destination **Named Address** is set in **Network > Static Routes** and **Address Range** is set to **Automatically assign addresses** in **VPN > SSL-VPN Settings**, SSL VPN should refresh the routing table automatically.

If your network configuration does not contain a default SSL VPN portal, you might receive the error message "Input value is invalid" when you attempt to access **VPN > SSL-VPN Portals**.

To enable a default portal - CLI:

```
config vpn ssl settings
    set default-portal <full-access | tunnel-access |
    web-access>
end
```

Adding bookmarks

A web bookmark can include login credentials to automatically log the SSL VPN user into the website. When the administrator configures bookmarks, the website credentials must be the same as the user's SSL VPN credentials. Users configuring their own bookmarks can specify alternative credentials for the website.

To add a bookmark - web-based manager:

1. On the **VPN > SSL-VPN Portals** page, ensure **Enable User Bookmarks** is enabled.
2. Select **Create New** and enter the following information:

Category	Select a category, or group, to include the bookmark. If this is the first bookmark added, you will be prompted to add a category. Otherwise, select Create from the drop-down list.
Name	Enter a name for the bookmark.
Type	Select the type of link from the drop-down list. Telnet, VNC, and RDP require a browser plugin. FTP and Samba replace the bookmarks page with an HTML file-browser.
URL	Enter the IP address source.
Description	Enter a brief description of the link.
Single Sign-On	<p>Enable if you wish to use Single Sign-On (SSO) for any links that require authentication.</p> <p>When including a link using SSO, be sure to use the entire URL. For example, <code>http://10.10.1.0/login</code>, rather than just the IP address.</p>

3. Select **OK**.

For more configuration options, see [Configuring SSL VPN web portals on page 2656](#).

Personal bookmarks

The administrator has the ability to view bookmarks the remote client has added to their SSL VPN login in the bookmarks widget. This enables the administrator to monitor and, if needed, remove unwanted bookmarks that do not meet with corporate policy.

To view and maintain remote client bookmarks, go to **VPN > SSL-VPN Personal Bookmarks**.

For more information about available bookmark applications, see [Applications available in the web portal on page 2690](#)

To enable personal bookmarks:

1. Go to **System > Feature Visibility**.
2. Enable **SSL-VPN Personal Bookmark Management**.
3. Select **Apply**.

Moving and cloning bookmarks

The administrator also has the ability to move and clone personal bookmarks in the GUI and CLI.

CLI syntax

```
config vpn ssl web user-bookmark
  edit 'name'
    config bookmarks
      move bookmark1 after/before
      clone bookmark1 to
    next
  end
```

Supporting browsers without plugins (Citrix/RDPNative/Port forward) - CLI only

CLI syntax

```
config vpn ssl web user-bookmark
  edit <name>
    config bookmarks
      edit "rdpnative"
        set apptype rdpnative
        set description "rdpnative"
        set host "172.16.68.188"
        set additional-params ''
        unset full-screen-mode
        set screen-height 768
        set screen-width 1024
      next
    end
  next
end
```

Group-based SSL VPN bookmarks

The administrator can add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client. This can only be done via the CLI.

To add group-based SSL VPN bookmarks - CLI:

```
config vpn ssl web portal
  edit "portal-name"
    set user-group-bookmark enable*/disable
  next
end
config vpn ssl web user-group-bookmark
  edit "group-name"
    config bookmark
      edit "bookmark1"
        ....
      next
    end
  next
end
```

Remote desktop bookmark creation with no password

If NLA security is chosen when creating an RDP bookmark, a username and password must be provided. However there may be instances where the user might want to use a blank password, despite being highly unrecommended. If a username is provided but the password is empty, the CLI will display a warning. See example CLI below, where the warning appears as a caution before finishing the command:

```
config vpn ssl web user-group-bookmark
  edit <group-name>
    config bookmarks
      edit <bookmark-name>
        set apptype rdp
        set host 172.16.200.121
        set security nla
        set port 3389
```

```

        set logon-user <username>
    next
end
Warning: password is empty. It might fail user authentication and remote desktop
connection would be failed.
end

```

If no username (logon-user) is specified, the following warning message will appear:

```

Please enter user name for RDP security method NLA. object set operator error, -2010
discard the setting Command fail. Return code -2010

```

SSO support for HTML5 RDP

This feature adds support for SSO from the SSL VPN portal to an RDP bookmark. If SSO is used, then the credentials used to login to SSL VPN will be automatically used when connecting to a remote RDP server.

This option is only available in CLI.

To configure SSO support for HTML5 RDP - CLI:

```

conf vpn ssl web user-bookmark
edit <name>
    config bookmarks
    edit <name>
        set apptype rdp
        set host "x.x.x.x"
        set port <value>
        set sso [disable | auto]
    next
end
next
end

```

SSL VPN Realms

You can go to **VPN > SSL-VPN Realms** and create custom login pages for your SSL VPN users. You can use this feature to customize the SSL VPN login page for your users and also to create multiple SSL VPN logins for different user groups.

In order to create a custom login page using the web-based manager, this feature must be enabled using **Feature Select**.

Before you begin, copy the default login page text to a separate text file for safe-keeping. Afterward, if needed, you can restore the text to the original version.

To configure SSL VPN Realms - web-based manager:

1. Configure a custom SSL VPN login by going to **VPN > SSL-VPN Realms** and selecting **Create New**. Users access different portals depending on the URL they enter.
2. The first option in the custom login page is to enter the path of the custom URL.
This path is appended to the address of the FortiGate unit interface to which SSL VPN users connect. The actual path for the custom login page appears beside the URL path field.
3. You can also limit the number of users that can access the custom login at any given time.

4. You can use HTML code to customize the appearance of the login page.
5. After adding the custom login, you must associate it with the users that will access the custom login. Do this by going to **VPN > SSL-VPN Settings** and adding a rule to the **Authentication/Portal Mapping** section.
6. Under **Authentication/Portal Mapping**, click **Create New** and select the user group(s) and the associated Realm.

To configure SSL VPN Realms - CLI:

```
config vpn ssl web realm
  edit <url-path>
    set login-page <content_str>
    set max-concurrent-user <int>
    set virtual-host <hostname_str>
  end
```

Where the following variables are set:

Variable	Description	Default
edit <url-path>	Enter the URL path to access the SSL-VPN login page. Do not include "http://".	No default.
login-page <content_str>	Enter replacement HTML for SSL-VPN login page.	No default.
max-concurrent-user <int>	Enter the maximum number of concurrent users allowed. Range 0-65 535. 0 means unlimited.	0
virtual-host <hostname_str>	Enter the virtual host name for this realm. Optional. Maximum length 255 characters.	No default.

Customizable FortiClient download URL

The attribute `customize-forticlient-download-url` (disabled by default) can be enabled to allow users to customize the download URL for FortiClient. This option is only available in CLI.

If enabled, two other attributes, `windows-forticlient-download-url` and `macos-forticlient-download-url`, will appear.

To configure a customizable FortiClient download URL- CLI:

```
config vpn ssl web portal
  edit <portal>
    set customize-forticlient-download-url {enable | disable}
    set windows-forticlient-download-url <custom URL for Windows>
    set macos-forticlient-download-url <custom URL for Mac OS>
  next
end
```

Disabling FortiClient download in the web portal

Use the following syntax to disable FortiClient download in the web portal.

```

config vpn ssl web portal
  edit <portal name>
    set forticlient-download disable
  next
end

```

Split DNS support

This feature allows you to specify which domains will be resolved by the DNS server specified by the VPN while all other domains will be resolved by the locally specified DNS. This is useful in both Enterprise and MSP scenarios (when hosting multiple SSL VPN portals). This option is only available in CLI.

To configure split DNS support - CLI:

```

config vpn ssl web portal
  edit <name>
    config split-dns-domains
      edit 1
        set domains "abc.com, cde.com"
        set dns-server1 192.168.1.1
        set dns-server2 192.168.1.2
        set ipv6-dns-server1 2000:2:3:4::5
        set ipv6-dns-server2 2000:2:3:4::6
      next
    ...
  end
end

```

Configuring security policies

You will need at least one SSL VPN security policy. This is an identity-based policy that authenticates users and enables them to access the SSL VPN web portal. The SSL VPN user groups named in the policy determine who can authenticate and which web portal they will use. From the web portal, users can access protected resources or download the SSL VPN tunnel client application.

This section contains the procedures needed to configure security policies for web-only mode operation and tunnel-mode operation. These procedures assume that you have already completed the procedures outlined in [Configuring security policies on page 2665](#).

If you will provide tunnel mode access, you will need a second security policy—an ACCEPT tunnel mode policy to permit traffic to flow between the SSL VPN tunnel and the protected networks.

Firewall addresses

Before you can create security policies, you need to define the firewall addresses you will use in those policies. For both web-only and tunnel mode operation, you need to create firewall addresses for all of the destination networks and servers to which the SSL VPN client will be able to connect.

For tunnel mode, you will already have defined firewall addresses for the IP address ranges that the FortiGate unit will assign to SSL VPN clients.

The source address for your SSL VPN security policies will be the predefined “all” address. Both the address and the netmask are 0.0.0.0. The “all” address is used because VPN clients will be connecting from various addresses, not just one or two known networks. For improved security, if clients will be connecting from one or

two known locations you should configure firewall addresses for those locations, instead of using the “all” address.

To create a firewall address, in the web-based manager, go to **Policy & Objects > Objects > Addresses**, and select **Create New**.

Create an SSL VPN security policy

At minimum, you need one SSL VPN security policy to authenticate users and provide access to the protected networks. You will need additional security policies only if you have multiple web portals that provide access to different resources. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

The SSL VPN security policy specifies:

- The incoming interface that corresponds to the ssl.root interface.
- The SSL VPN user groups that can use the security policy.
- The times (schedule) and types of services that users can access.
- The UTM features and logging that are applied to the connection.

Do not use ALL as the destination address. If you do, you will see the “Destination address of Split Tunneling policy is invalid” error when you enable Split Tunneling.

To create an SSL-VPN security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information:

Incoming Interface	Select the virtual SSL VPN interface, such as ssl.root .
Outgoing Interface	Select the FortiGate network interface that connects to the protected network.
Source	Select to allow access only to holders of a (shared) group certificate. The holders of the group certificate must be members of an SSL VPN user group, and the name of that user group must be present in the Allowed field. See Configuring security policies on page 2665 .
Source User Group	SSL VPN
Destination Address	<p>Select the firewall address you created that represents the networks and servers to which the SSL VPN clients will connect.</p> <p>If you want to associate multiple firewall addresses or address groups with the Destination Interface/Zone, from Destination Address, select the plus symbol. In the dialog box, move the firewall addresses or address groups from the Available Addresses section to the Members section, then select OK.</p>
Schedule	Select always .

Service	Select services in the left list and use the right arrow button to move them to the right list. Select the ALL service to allow the user group access to all services.
Action	Select Accept .

Your identity-based policies are listed in the security policy table. The FortiGate unit searches the table from the top down to find a policy to match the client's user group. Using the move icon in each row, you can change the order of the policies in the table to ensure the best policy will be matched first. You can also use the icons to edit or delete policies. Furthermore, you can drag and drop policies in the policy list to rearrange their order.

To create an SSL VPN security policy - CLI:

Create the SSL VPN security policy by entering the following CLI commands.

```
config firewall policy
  edit <id>
    set srcintf ssl.root(sslvpn tunnel interface)
    set dstintf port2
    set srcaddr all
    set dstaddr OfficeLAN
    set nat enable
    set groups <name>
  end
```

Create a tunnel mode security policy

If your SSL VPN will provide tunnel mode operation, you need to create a security policy to enable traffic to pass between the SSL VPN virtual interface and the protected networks. This is in addition to the SSL VPN security policy that you created in the preceding section.

The SSL VPN virtual interface is the FortiGate unit end of the SSL tunnel that connects to the remote client. It is named `ssl.<vdom_name>`. In the root VDOM, for example, it is named `ssl.root`. If VDOMs are not enabled on your FortiGate unit, the SSL VPN virtual interface is also named `ssl.root`.

To configure the tunnel mode security policy - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface, such as ssl.root .
Outgoing Interface	Select the FortiGate network interface that connects to the protected network.
Source Address	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients, such as <code>SSL_VPN_tunnel_users</code> .
Source User(s)	Select to allow access only to holders of a (shared) group certificate. The holders of the group certificate must be members of an SSL VPN user group, and the name of that user group must be present in the Allowed field. See Configuring security policies on page 2665 .

Destination Address	Select the firewall address that represents the networks and servers to which the SSL VPN clients will connect. To select multiple firewall addresses or address groups, select the plus sign next to the drop-down list.
Schedule	Select always .
Service	Select services in the left list and use the right arrow button to move them to the right list. Select the ALL service to allow the user group access to all services.
Action	Select Accept .
Enable NAT	Select Enable NAT. (Optional)

To configure the tunnel mode security policy - CLI:

```
config firewall policy
  edit <id>
    set srcintf ssl.root(sslvpn tunnel interface)
    set dstintf <dst_interface_name>
    set srcaddr <tunnel_ip_address>
    set dstaddr <protected_network_address_name>
    set schedule always
    set service ALL
    set nat enable
    set groups <name>
  end
```

This policy enables the SSL VPN client to initiate communication with hosts on the protected network. If you want to enable hosts on the protected network to initiate communication with the SSL VPN client, you should create another Accept policy like the preceding one but with the source and destination settings reversed.

You must also add a static route for tunnel mode operation.

Routing for tunnel mode

If your SSL VPN operates in tunnel mode, you must add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager:

1. Go to **Network > Static Routes** and select **Create New**.

For low-end FortiGate units, go to **System > Network > Routing** and select **Create New**.

2. Enter the **Destination IP/Mask** of the tunnel IP address that you assigned to the users of the web portal.
3. Select the SSL VPN virtual interface for the **Device**.
4. Select **OK**.

To add the tunnel mode route - CLI:

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
```

```

edit <id>
    set device ssl.root
    set dst 10.11.254.0/24
end

```

Split tunnel Internet browsing policy

With split tunneling disabled, all of the SSL VPN client's requests are sent through the SSL VPN tunnel. But the tunnel mode security policy provides access only to the protected networks behind the FortiGate unit. Clients will receive no response if they attempt to access Internet resources. You can enable clients to connect to the Internet through the FortiGate unit using a split tunnel Internet browsing policy.

To add an Internet browsing policy:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface (ssl.root , for example).
Outgoing Interface	Select the FortiGate network interface that connects to the Internet.
Source	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients.
Source User Group	SSL VPN
Destination Address	Select All .
Action	Select Accept .
Enable NAT	Select Enable .

To configure the Internet browsing security policy - CLI:

To enable browsing the Internet through port1, you would enter:

```

config firewall policy
edit 0
    set srcintf ssl.root
    set dstintf port1
    set srcaddr SSL_tunnel_users
    set dstaddr all
    set schedule always
    set service ALL
    set nat enable
    set groups <name>
end

```

Enabling a connection to an IPsec VPN

You might want to provide your SSL VPN clients access to another network, such as a branch office, that is connected by an IPsec VPN. To do this, you need only to add the appropriate security policy. For information about route-based and policy-based IPsec VPNs, see the [IPsec VPN Guide](#).

Route-based connection

To configure interconnection with a route-based IPsec VPN - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface (ssl.root , for example).
Outgoing Interface	Select the virtual IPsec interface for your IPsec VPN.
Source	Select the firewall address that represents the IP address range assigned to SSL VPN clients.
Source User Group	SSL VPN
Destination Address	Select the address of the IPsec VPN remote protected subnet.
Action	Select ACCEPT .
Enable NAT	Enable.

To configure interconnection with a route-based IPsec VPN - CLI:

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the toOfficeA IPsec VPN, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf toOfficeA
    set srcaddr SSL_tunnel_users
    set dstaddr OfficeAnet
    set action accept
    set nat enable
    set schedule always
    set service ALL
    set groups <name>
  end
```

Policy-based connection

To configure interconnection with a policy-based IPsec VPN - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and select **OK**.

Incoming Interface	Select the virtual SSL VPN interface (ssl.root , for example).
Outgoing Interface	Select the FortiGate network interface that connects to the Internet.
Source	Select the firewall address that represents the IP address range assigned to SSL VPN clients.

Source User Group	SSL VPN
Destination Address	Select the address of the IPsec VPN remote protected subnet.

3. Configure inbound NAT from the CLI:

```
config firewall policy
  edit 0
    set natinbound enable
    set groups <name>
  end
```

To configure interconnection with a policy-based IPsec VPN - CLI:

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the OfficeA IPsec VPN, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf port1
    set srcaddr SSL_tunnel_users
    set dstaddr OfficeAnet
    set action ipsec
    set schedule always
    set service ALL
    set inbound enable
    set outbound enable
    set natinbound enable
    set vpntunnel OfficeA
    set groups <name>
  end
```

In this example, port1 is connected to the Internet.

Configuring encryption key algorithms

The FortiGate unit supports a range of cryptographic cipher suites to match the capabilities of various web browsers. The web browser and the FortiGate unit negotiate a cipher suite before any information (for example, a user name and password) is transmitted over the SSL link. You can only configure encryption key algorithms for SSL VPN in the CLI.

To configure encryption key algorithms - CLI:

Use the following CLI command,

```
config vpn ssl settings
  set algorithm <cipher_suite>
end
```

where one of the following variables replaces *<cipher_suite>*:

Variable	Description
low	Use any cipher suite; AES, 3DES, RC4, DES, or ChaCha.
medium	Use a 128-bit or greater cipher suite; AES, 3DES, RC4, or ChaCha.
high	Use a cipher suite greater than 128 bits; AES or ChaCha.

Note that the `algorithm <cipher_suite>` syntax is only available when the `sslvpn-enable` attribute is set to **enable**.

Controlling the use of specific cipher suites

Administrators can ban the use of specific cipher suites in the CLI for SSL VPN, so PCI-DSS (Payment Card Industry Data Security Standard) certification can be met.

To ban the use of specific cipher suites for SSL VPN - CLI:

```
config vpn ssl settings
  set banned-cipher [RSA | DH | DHE | ECDH | ECDHE | DSS | ECDSA | AES | AESGCM |
    CAMELLIA | 3DES | SHA1 | SHA256 | SHA384 | STATIC]
```

Additional configuration options

Beyond the basics of setting up the SSL VPN, you can configure a number of other options that can help to ensure your internal network is secure and can limit the possibility of attacks and viruses entering the network from an outside source.

Routing in tunnel mode

If you are creating a SSL VPN connection in tunnel mode, you need to add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager:

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the **Destination IP/Mask** of the tunnel IP address that you assigned to the users of the web portal.
3. Select the SSL VPN virtual interface for the **Device**.
4. Select **OK**.

To add the tunnel mode route - CLI:

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
  edit <id>
    set device ssl.root
    set dst 10.11.254.0/24
  end
```

Changing the port number for web portal connections

You can specify a different TCP port number for users to access the web portal login page through the HTTPS link. By default, the port number is 443 and users can access the web portal login page using the following default URL:

```
https://<FortiGate_IP_address>:443/remote/login
```

where <FortiGate_IP_address> is the IP address of the FortiGate interface that accepts connections from remote users.

To change the SSL VPN port - web-based manager:

1. If **Current VDOM** appears at the bottom left of the screen, select **Global** from the list of VDOMs.
2. Go to **VPN > SSL-VPN Settings**.
3. Type an unused port number in the **Listen on Port** field and select **Apply**.

To change the SSL VPN port - CLI:

This is a global setting. For example, to set the SSL VPN port to 10443, enter the following:

```
config vpn ssl settings
    set port 10443
end
```

HTTP to HTTPS redirect support

The admin HTTP port can be redirected to the admin HTTPS port. This is enabled in **VPN > SSL-VPN Settings** using the option **Redirect port 80 to this login port**.

There are two likely scenarios for this:

- SSL VPN is not in use, in which case the admin GUI runs on port 443 or 10443, and port 80 is redirected.
- SSL VPN runs on port 443, in which case port 80 is redirected to 443 and the admin port runs on 10443.

If the administrator chooses to run SSL VPN on port 80, the redirect option is invalid.

This can also be configured in the CLI as described below:

To redirect HTTP to HTTPS port - CLI:

```
config vpn ssl settings
    set https-redirect [enable | disable] (default: disabled)
end
```

SSL offloading

To configure SSL offloading, which allows or denies client renegotiation, you must use the CLI. This helps to resolve the issues that affect all SSL and TLS servers that support renegotiation, identified by the Common Vulnerabilities and Exposures system in CVE-2009-3555. The SSL offloading renegotiation feature is considered a workaround until the IETF permanently resolves the issue.

The CLI command is `ssl-client-renegotiation` and is found under the `config firewall vip` syntax.

Host check

When you enable AV, FW, or AV-FW host checking in the web portal Security Control settings, each client is checked for security software that is recognized by the Windows Security Center. As an alternative, you can create a custom host check that looks for security software selected from the Host Check list. For more information, see [Additional configuration options on page 2672](#).

The Host Check list includes default entries for many security software products.

Host integrity checking is only possible with client computers running Microsoft Windows platforms.

To configure host checking - CLI:

To configure the full-access portal to check for AV and firewall software on client Windows computers, you would enter the following:

```
config vpn ssl web portal
  edit full-access
    set host-check av-fw
  end
```

To configure the full-access portal to perform a custom host check for FortiClient Host Security AV and firewall software, you would enter the following:

```
config vpn ssl web portal
  edit full-access
    set host-check custom
    set host-check-policy FortiClient-AV FortiClient-FW
  end
```

Replacing the host check error message

You can add your own host security check error message using either the web-based manager or the CLI. The default message reads: “Your PC does not meet the host checking requirements set by the firewall. Please check that your OS version or antivirus and firewall applications are installed and running properly or you have the right network interface.”

To replace the host check error message - web-based manager:

1. Navigate to **System > Replacement Messages** and select **Extended View** in the upper right corner.
2. Scroll down to **SSL VPN** and select **Hostcheck Error Message**.
3. Edit the text in the right-hand column below and select **Save**.
If you are unhappy with the new message, you can restore the message to its default by selecting **Restore Default** instead of **Save**.

To replace the host check error message - CLI:

Configure the host check error message using the following command.

```
config system replacemsg sslvpn hostcheck-error
```

Creating a custom host check list

You can add your own software requirements to the host check list using the CLI. Host integrity checking is only possible with client computers running Microsoft Windows platforms. Enter the following commands:

```
config vpn ssl web host-check-software
  edit <software_name>
    set guid <guid_value>
    set type <av | fw>
    set version <version_number>
  end
```

If known, enter the Globally Unique Identifier (GUID) for the host check application. Windows uses GUIDs to identify applications in the Windows Registry. The GUID can be found in the Windows registry in the HKEY_CLASSES_ROOT section.

To obtain the exact versioning, in Windows, right-click on the .EXE file of the application and select **Properties**, then select the **Version** tab.

Example Tunnel Mode Host Check - Registry Key Check

- Check to see if a required registry key is present:

```
config vpn ssl web host-check-software
  edit <computer_name>
    config check-item-list
      edit 1
        set target "HKEY_LOCAL_MACHINE\\SYSTEM\\CurrentControlSet\\Control\\ComputerName\\ActiveComputerName:ComputerName=WINXP32SP3B62"
        set type registry <<<-----
      next
    end
  next
end
```

Example Tunnel Mode Host Check - Application Running Check

- Check to see if a required application is installed and/or running:

```
config vpn ssl web host-check-software
  edit "calc"
    config check-item-list
      edit 1
        set target "calc.exe"
        set type process <<<-----
      next
    end
  next
end
```

Example Tunnel Mode Host Check - File Check

- Check to see if a specific file exists at a specific location:

```
config vpn ssl web host-check-software
  edit "putty"
    config check-item-list
      edit 1
```

```

        set target "C:\\software\\putty.txt"
        set md5s <ENC>
    next
end
next
end

```

Mac OS host check

This feature provides the host check function for Mac OS to SSL VPN. The following Mac OS hosts can be allowed, denied, or checked:

- macos-high-sierra-10.13
- macos-sierra-10.12
- os-x-el-capitan-10.11
- os-x-yosemite-10.10
- os-x-mavericks-10.9

The `os-type` option is available under `vpn ssl web host-check-software`; if `os-type` is `macos`, then `type`, `version` and `guid` are hidden. Furthermore, `type` in `check-item-list` can only be set to `file` or `process`.

SSL VPN Host check support is currently not planned for iOS or Android.

To configure Mac OS host check - CLI:

```

config vpn ssl web portal
  edit <name>
    set os-check enable
    config os-check-list macos-high-sierra-10.13
      set action {allow | deny | check-up-to-date}
      set tolerance <value>
      set latest-patch-level <value>
    next
  end
next
end

config vpn ssl web host-check-software
  edit <name>
    set os-type macos
    config check-item-list
      edit <name>
        set type process
        set target "calc.exe"
      next
    end
  [...]
next
end

```

Configuring virtual desktop

Available for 32-bit Windows XP, Windows Vista, and Windows 7 client PCs, the virtual desktop feature completely isolates the SSL VPN session from the client computer's desktop environment. All data is encrypted,

including cached user credentials, browser history, cookies, temporary files, and user files created during the session. When the SSL VPN session ends normally, the files are deleted. If the session ends due to a malfunction, files might remain, but they are encrypted so that the information is protected.

When the user starts an SSL VPN session that has virtual desktop enabled, the virtual desktop replaces the user's normal desktop. When the virtual desktop exits, the user's normal desktop is restored.

Virtual desktop requires the Fortinet cache cleaner plugin. If the plugin is not present, it automatically downloads to the client computer.

To enable virtual desktop :

To enable virtual desktop on the full-access portal and apply the application control list 'List1', for example, you would enter:

```
config vpn ssl web portal
  edit full-access
    set virtual-desktop enable
    set virtual-desktop-app-list List1
  end
```

Configuring virtual desktop application control

You can control which applications users can run on their virtual desktop. To do this, you create an Application Control List of either allowed or blocked applications. When you configure the web portal, you select the list to use.

Configure the application control list in the CLI.

To create an Application Control List - CLI:

If you want to add 'BannedApp' to 'List1', a list of blocked applications, you would enter:

```
config vpn ssl web virtual-desktop-app-list
  edit "List1"
    set action block
    config apps
      edit "BannedApp"
        set md5s "06321103A343B04DF9283B80D1E00F6B"
      end
    end
  end
```

Configuring client OS Check

The SSLVPN client OS Check feature can determine if clients are running the Windows 2000, Windows XP, Windows Vista, Windows 7, or Windows 10 operating system. You can configure the OS Check to do any of the following:

- Allow the client access.
- Allow the client access only if the operating system has been updated to a specified patch (service pack) version.
- Deny the client access.

The OS Check has no effect on clients running other operating systems.

The Windows patch check enables you to define the minimum Windows version and patch level allowed when connecting to the SSL VPN portal. When the user attempts to connect to the web portal, FortiOS performs a

query on the version of Windows the user has installed. If it does not match the minimum requirement, the connection is denied. The Windows patch check is configured in the CLI.

To specify the acceptable patch level, you set the `latest-patch-level` and the `tolerance`. The lowest acceptable patch level is `latest-patch-level` minus `tolerance`. In this case, `latest-patch-level` is 3 and `tolerance` is 1, so 2 is the lowest acceptable patch level.

To configure OS Check:

OS Check is configurable only in the CLI.

```
config vpn ssl web portal
  edit <portal_name>
    set os-check enable
    config os-check-list [windows-2000 | windows-xp | windows-vista | windows-7 |
      windows-10]
      set action [allow | check-up-to-date | deny]
      set latest-patch-level [disable | 0 - 255]
      set tolerance <tolerance_num>
    end
  end
```

Host check for Windows firewall

The Windows built-in firewall does not have a GUID in `root\securitycenter` or `root\securitycenter2`, but you can use a registry value to detect the firewall status.

If Windows firewall is on, the following registry value will be set to 1:

- **KeyName:** `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SharedAccess\Parameters\FirewallPolicy\StandardProfile`
- **ValueName:** `EnableFirewall`

In FortiOS, use the `registry-value-check` feature to define the Windows Firewall software by entering the following in the CLI:

```
config vpn ssl web host-check-software
  edit "Microsoft-Windows-Firewall"
    config check-item-list
      edit 1
        set target
          "HKLM\\SYSTEM\\CurrentControlSet\\Services\\SharedAccess\\Parameters\\Firew
            allPolicy\\StandardProfile:EnableFirewall==1"
        set type registry
      next
      edit 2
        set target
          "HKLM\\SYSTEM\\CurrentControlSet\\Services\\SharedAccess\\Parameters\\Firew
            allPolicy\\PublicProfile:EnableFirewall==1"
        set type registry
      next
      edit 3
        set target
          "HKLM\\SYSTEM\\CurrentControlSet\\Services\\SharedAccess\\Parameters\\Firew
            allPolicy\\DomainProfile:EnableFirewall==1"
        set type registry
      next
    end
```

```
set type fw
next
set host-check custom
set host-check-policy Microsoft-Windows-Firewall
```

Adding WINS and DNS services for clients

You can specify the WINS or DNS servers that are made available to SSL-VPN clients.

DNS servers provide the IP addresses that browsers need to access web sites. For Internet sites, you can specify the DNS server that your FortiGate unit uses. If SSL VPN users will access intranet sites using URLs, you need to provide them access to the intranet's DNS server. You specify a primary and a secondary DNS server.

A WINS server provides IP addresses for named servers in a Windows domain. If SSL VPN users will access a Windows network, you need to provide them access to the domain WINS server. You specify a primary and a secondary WINS server.

To specify WINS and DNS services for clients - web-based manager:

1. Go to **VPN > SSL-VPN Settings**.
2. Next to **DNS Server** select **Specify**.
3. Enter the IP addresses of DNS servers in the **DNS Server** fields as needed. Fields are available for both IPv4 and IPv6 addresses.
4. Select **Specify WINS Servers**, and enter the IP addresses of WINS servers in the **WINS Server** fields as needed. Fields are available for both IPv4 and IPv6 addresses.
5. Select **Apply**.

To specify WINS and DNS services for clients - CLI:

```
config vpn ssl settings
  set dns-server1 <address_ipv4>
  set dns-server2 <address_ipv4>
  set wins-server1 <address_ipv4>
  set wins-server2 <address_ipv4>
end
```

Idle timeout

The idle timeout setting controls how long the connection can remain idle before the system forces the remote user to log in again. For security, keep the default value of 5000 seconds or less. Set the timeout value to 0 to disable idle timeouts.

To set the idle timeout - web-based manager:

1. Go to **VPN > SSL-VPN Settings** and enable **Idle Logout**.
2. In the **Inactive For** field, enter the timeout value.
The valid range is from 10 to 28800 seconds.
3. Select **Apply**.

To set the idle timeout - CLI:

```
config vpn ssl settings
  set idle-timeout <seconds_int>
```

```
end
```

Login timeout

With long network latency, the FortiGate can timeout the client before it can finish negotiation processes, such as DNS lookup and time to enter a token. Two CLI commands under `config vpn ssl settings` allow the login timeout to be configured, replacing the previous hard timeout value. The second command can be used to set the SSL VPN maximum DTLS hello timeout.

CLI syntax

```
config vpn ssl settings
  edit <example>
    set login-timeout [10-180] Default is 30 seconds.
    set dtls-hello-timeout [10-60] Default is 10 seconds.
end
```

Login failure limit

The following CLI allows the administrator to configure the number of times wrong credentials are allowed before the SSL VPN server blocks an IP address, and also how long the block would last.

CLI syntax

```
config vpn ssl settings
  set login-attempt-limit [0-10] Default is 2.
  set login-block-time [0-86400] Default is 60 seconds.
end
```

SSL VPN logs

Logging is available for SSL VPN traffic so you can monitor users connected to the FortiGate unit and their activity. For more information on configuring logs on the FortiGate unit, see the [Logging and Reporting Guide](#).

To enable logging of SSL VPN events - web-based manager:

1. Go to **Log & Report > Log Settings**.
2. Enable **Event Logging**, and select **VPN activity event**.
3. Select **Apply**.

To view the SSL VPN log data, in the web-based manager, go to **Log & Report** and select either the **Event Log** or **Traffic Log**.

In event log entries, look for the sub-types “sslvpn-session” and “sslvpn-user”.

For information about how to interpret log messages, see the [FortiGate Log Message Reference](#).

Monitoring active SSL VPN sessions

You can go to **User & Device > Monitor** to view a list of active SSL VPN sessions. The list displays the user name of the remote user, the IP address of the remote client, and the time the connection was made. You can also see which services are being provided, and delete an active web session from the FortiGate unit.

To monitor SSL VPNs - web-based manager:

To view the list of active SSL VPN sessions, go to **Monitor > SSL-VPN Monitor**.

When a tunnel-mode user is connected, the **Description** field displays the IP address that the FortiGate unit assigned to the remote host.

If required, you can end a session/connection by selecting its checkbox and then clicking the **Delete** icon.

Importing and using a CA-signed SSL certificate

Use the following set of instructions to import a CA-signed SSL certificate and configure an SSL VPN using that certificate.

Import the signed certificate into your FortiGate device

1. Unzip the file downloaded from the CA.
There should be two .CRT files: a CA certificate with bundle in the file name, and a local certificate.
2. Log in to your FortiGate unit and browse to **System > Certificates**.
3. Select **Create New > Local Certificate** to import the local certificate.
The status of the certificate will change from PENDING to OK.
4. Import the CA certificate by selecting **Import > CA Certificate**.
It will be listed in the CA Certificates section of the certificates list. You can now configure SSL VPN using the signed certificate.

Configure your FortiGate device to use the signed certificate

1. Log in to your FortiGate unit and browse to **VPN > SSL-VPN Settings**.
2. In the **Connection Settings** section, locate the **Server Certificate** field.
3. Select the new certificate from the drop-down menu.
4. Select **Apply** to configure SSL VPN to use the new certificate.

Implement post-authentication CSRF protection in SSL VPN web mode

This attribute can enable/disable verification of a referrer in the HTTP request header in order to prevent a Cross-Site Request Forgery attack.

CLI Syntax

```
config vpn ssl settings
    set check-referer [enable|disable]
end
```

DTLS support

The Datagram Transport Layer Security (DTLS) protocol is supported for SSL VPN connections. DTLS allows datagram-based applications to communicate in a way that prevents eavesdropping, tampering, or message forgery. It can also be used to improve upload/download throughput. It is similar to the Transport Layer Security (TLS) protocol.

DTLS support can be enabled in the CLI as described below.

CLI Syntax

```
config vpn ssl settings
    set dtls-tunnel [enable | disable] (default: enabled)
end
```

Allow firewall address to be used in routing table for SSL VPN

If destination **Named Address** is set in **Network > Static Routes** and **Address Range is set to Automatically assign addresses** is enabled in **VPN > SSL-VPN Settings**, SSL VPN should refresh the routing table automatically.

To view the routes in the routing table, go to **Monitor > Routing Monitor**.

WAN link load balancing

You can set `virtual-wan-link` as the destination interface in a firewall policy (when SSL VPN is the source interface) for WAN link load balancing. This allows logging into a FortiGate via SSL VPN for traffic inspection and then have outbound traffic load balanced by WAN link load balancing.

CLI syntax

```
config firewall policy
  edit <example>
    set dstintf virtual-wan-link
  end
```

The SSL VPN client

The remote client connects to the SSL VPN tunnel in various ways, depending on the VPN configuration.

- Tunnel mode establishes a connection to the remote protected network that any application can use. If the client computer runs Microsoft Windows, they can download the tunnel mode client from the web portal. If the client computer runs Linux or Mac OS X, the user needs to download the tunnel mode client application from the Fortinet Support web site. See the Release Notes for your FortiOS firmware for the specific operating system versions that are supported.
- The virtual desktop application creates a virtual desktop on a user's PC and monitors the data read/write activity of the web browser running inside the virtual desktop. When the application starts, it presents a 'virtual desktop' to the user. The user starts the web browser from within the virtual desktop and connects to the SSL VPN web portal. The browser file/directory operation is redirected to a new location, and the data is encrypted before it is written to the local disk. When the virtual desktop application exits normally, all the data written to the disk is removed. If the session terminates abnormally (power loss, system failure, etc.), the data left behind is encrypted and unusable to the user. The next time you start the virtual desktop, the encrypted data is removed.

The SSL VPN standalone client installer for Windows is no longer supported in FortiOS 5.4. Users should use the FortiClient installer with the "VPN Only" option instead.

FortiClient

Remote users can use the FortiClient software to initiate an SSL VPN tunnel to connect to the internal network. FortiClient uses local port TCP 1024 to initiate an SSL encrypted connection to the FortiGate unit, on port TCP 443. When connecting using FortiClient, the FortiGate unit authenticates the FortiClient SSL VPN request based on the user group options. The FortiGate unit establishes a tunnel with the client and assigns a virtual IP address to the client PC. Once the tunnel has been established, the user can access the network behind the FortiGate unit.

FortiClient software is available for download at www.forticlient.com and is available for Windows, Mac OS X, Apple iOS, and Android.

Tunnel mode client configuration

The FortiClient SSL VPN tunnel client requires basic configuration by the remote user to connect to the SSL VPN tunnel. When distributing the FortiClient software, provide the following information for the remote user to enter once the client software has been started. Once entered, they can select **Connect** to begin an SSL VPN session.

Connection Name	If you have pre-configured the connection settings, select the connection from the list and then select Connect . Otherwise, enter the settings in the fields below.
Remote Gateway	Enter the IP address or FQDN of the FortiGate unit that hosts the SSL VPN.

Username	Enter your username.
Client Certificate	<p>Use this field if the SSL VPN requires a certificate for authentication.</p> <p>Select the required certificate from the drop-down list. The certificate must be installed in the Internet Explorer certificate store.</p>

The SSL VPN web portal

This chapter explains how to use and configure the web portal features. This chapter is written for end users as well as administrators.

The following topics are included:

Connecting to the FortiGate unit

You can connect to the FortiGate unit using a web browser. The URL of the FortiGate interface may vary from one installation to the next. If required, ask your FortiGate administrator for the URL of the FortiGate unit, and obtain a user name and password. You can connect to the web portal using an Android phone, iPhone, or iPad. The FortiGate unit will display the content of the portal to fit the device's screen.

In addition, if you will be using a personal or group security (X.509) certificate to connect to the FortiGate unit, your web browser may prompt you for the name of the certificate. Your FortiGate administrator can tell you which certificate to select.

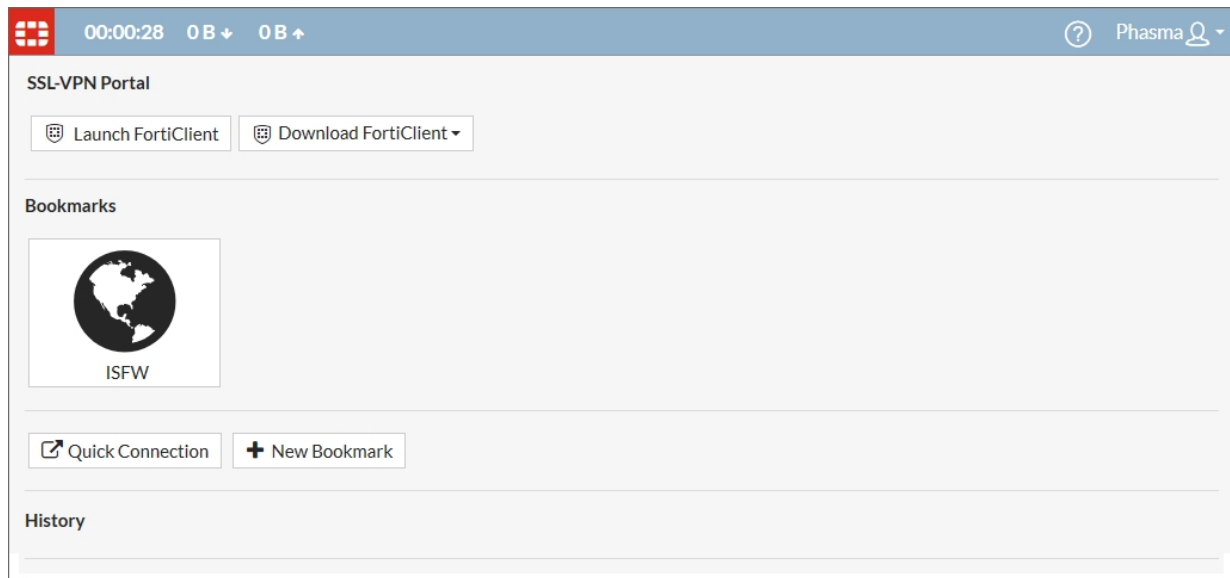

To log into the secure FortiGate HTTP gateway

1. Using the web browser on your computer, browse to the URL of the FortiGate unit (for example, `https://<FortiGate_IP_address>:443/remote/login`). The FortiGate unit may offer you a self-signed security certificate. If you are prompted to proceed, select **Yes**.
A second message may be displayed to inform you that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit is attempting to redirect your web browser connection. You can ignore the message.
2. When you are prompted for your user name and password:
 - In the **Name** field, type your user name.
 - In the **Password** field, type your password.
3. Select **Login**.
The FortiGate unit will redirect your web browser to the FortiGate SSL VPN web portal home page automatically.

Web portal overview

To log into the web portal, the user must have valid username and password credentials, as well as any other factor of authentication that may be configured, such as a FortiToken code.

After logging in to the web portal, the remote user is presented with a web portal page similar to the following:

Various widgets provide the web portal's features:

- **Session Information** displays the elapsed time since login and the volume of HTTP and HTTPS traffic, both inbound and outbound.
- **Quick Connection** enables you to connect to network resources without using or creating a bookmark.
- **Download Forticlient** provides access to the FortiClient tunnel application for various operating systems.
- **Bookmarks** provides links to network resources. You can use the administrator-defined bookmarks and you can add your own bookmarks.

While using the web portal, you can select the **Help** button to get information to assist you in using the portal features. This information displays in a separate browser window.

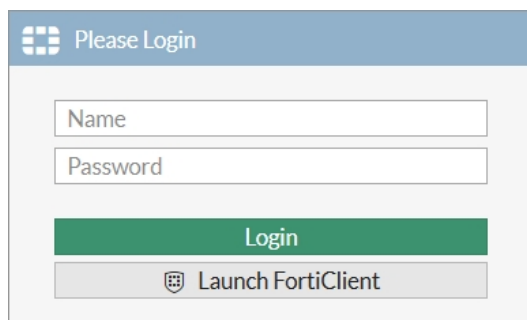

When you have finished using the web portal, select the **Logout** button in the top right corner of the portal window.

After making any changes to the web portal configuration, be sure to select **Apply**.

The Launch FortiClient button

A **Launch FortiClient** button appears on the SSL VPN login page on non-Linux environments when SSL VPN is in tunnel mode.

A similar button is also available within the web portal.

When the user clicks the Launch FortiClient button:

- If FortiClient is installed, FortiClient opens and the GUI switches to the **Remote Access** VPN tab (but FortiClient does *not* automatically create a VPN connection based on the web-mode connection information).
- If FortiClient is not installed, nothing happens.

The **Launch FortiClient** button only works for Mac and Windows operating systems. This feature is not applicable to operating systems that do not support FortiClient, such as Linux and Android phone.

For more information, refer to [The SSL VPN client](#) section.

Portal configuration

The SSL VPN web portal enables users to access network resources through a secure channel using a web browser. Fortinet administrators can configure log in privileges for system users and which network resources are available to the users.

The portal configuration determines what the user sees when they log in to the portal. Both the system administrator and the user have the ability to customize the SSL VPN portal.

There are three pre-defined default web portal configurations available:

- **full-access**: Includes all widgets available to the user - **Session Information**, **Tunnel Mode** options, **Connection Launcher**, **Remote Desktop**, and **Predefined Bookmarks**.
- **tunnel-access**: Includes **Session Information** and **Tunnel Mode** options.
- **web-access**: Includes **Session Information** and **Predefined Bookmarks** widgets.

You can also create your own web portal to meet your corporate requirements.

Portal page	
Create New	Creates a new web portal.
Edit	Select a portal from the list to enable the Edit option, and modify the portal configuration.
Delete	Removes a portal configuration. To remove multiple portals from the list, select the check box beside the portal names, then select Delete .
Name	The name of the web portal.

Portal page

Ref.

Displays the number of times the object is referenced in other configurations on the FortiGate unit, such as security policies.

To view the location of the referenced object, select the number in **Ref.** column.

To view more information about how the object is used, select one of:

View the list page for these objects – automatically redirects you to the list page where the object is referenced at.

Edit this object – modifies settings within that particular setting that the object is referenced with.

View the details for this object – similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with.

Portal settings

A web portal defines SSL VPN user access to network resources. The portal configuration determines what SSL VPN users see when they log in to the unit. Both the Fortinet administrator and the SSL VPN user have the ability to customize the web portal settings. Portal settings are configured in **VPN > SSL-VPN Portals**.

The following settings are available, allow you to configure general and security console options for your web portal.

Portal Setting	Description
Name	The name for the portal.
Limit Users to One SSL-VPN Connection at a Time	You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again. This option is disabled by default.
Tunnel Mode	These settings determine how tunnel mode clients are assigned IPv4 addresses.

Portal Setting	Description
Enable Split Tunneling	<p>Select so that the VPN carries only the traffic for the networks behind the FortiGate unit. The user's other traffic follows its normal route.</p> <p>If you enable split tunneling, you are required to set the Routing Address, which is the address that your corporate network is using. Traffic intended for the Routing Address will not be split from the tunnel.</p>
Source IP Pools	Select an IP Pool for users to acquire an IP address when connecting to the portal. There is always a default pool available if you do not create your own.
Tunnel Mode Client Options	<p>These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default.</p> <ul style="list-style-type: none"> • Allow client to save password - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN. • Allow client to connect automatically - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel. • Allow client to keep connections alive - When enabled, if the user selects this option, the FortiClient should try to reconnect once it detects the VPN connection is down unexpectedly (not manually disconnected by user).
Enable Web Mode	Select to enable web mode access.
Portal Message	This is a text header that appears on the top of the web portal.
Theme	Select a color styling specifically for the web portal.
Show Session Information	The Show Session Information widget displays the login name of the user, the amount of time the user has been logged in and the inbound and outbound traffic statistics.
Show Connection Launcher	Displays the Connection Launcher widget in the web portal.
Show Login History	Select to include user login history on the web portal.

Portal Setting	Description
User Bookmarks	Enable to allow users to add their own bookmarks in the web portal.
Predefined Bookmarks	Select to include bookmarks on the web portal. Bookmarks are used as links to internal network resources. When a bookmark is selected from a bookmark list, a pop-up window appears with the web page. Telnet, VNC, and RDP require a browser plugin. FTP and Samba replace the bookmarks page with an HTML file-browser.

Predefined Bookmarks

Bookmarks are used as links to specific resources on the network. When a bookmark is selected from a bookmark list, a pop-up window appears with the requested web page. Telnet, RDP, and VNC pop up a window that requires a browser plug-in. FTP and Samba replace the bookmarks page with an HTML file-browser.

Note that the RDP/VNC web portals are **not** supported for the following platforms:

Platform	Model
FortiGate	80D, 92D, 200D, 200D-POE, 240D, 240D-POE, 600C, 800C, 1000C, 3240C, 3600C, and 5001C
FortiGate-Rugged	90D
FortiWiFi	92D

A web bookmark can include login credentials to automatically log the SSL VPN user into the web site. When the administrator configures bookmarks, the web site credentials must be the same as the user's SSL VPN credentials. Users configuring their own bookmarks can specify alternative credentials for the web site.

Applications available in the web portal

Depending on the web portal configuration and user group settings, one or more of the following server applications are available to you through **Predefined Bookmarks**, as well as the **Quick Connection** widget:

- Citrix makes use of SOCKS so that the Citrix client can connect to the SSL VPN port forward module to provide the connection.
- FTP (File Transfer Protocol) enables you to transfer files between your computer and a remote host.
- HTTP/HTTPS accesses web pages.
- Port Forward provides the middle ground between web mode and tunnel mode. When the SSL VPN receives data from a client application, the data is encrypted and sent to the FortiGate unit, which then forwards the traffic to the application server.
- RDP (Remote Desktop Protocol), similar to VNC, enables you to remotely control a computer running Microsoft Terminal Services.
- SMB/CIFS implements the Server Message Block (SMB) protocol to support file sharing between your computer and a remote server host.
- SSH (Secure Shell) enables you to exchange data between two computers using a secure channel.

- TELNET (Teletype Network emulation) enables you to use your computer as a virtual text-only terminal to log in to a remote host.
- VNC (Virtual Network Computing) enables you to remotely control another computer, for example, accessing your work computer from your home computer.

Some server applications may prompt you for a user name and password. You must have a user account created by the server administrator so that you can log in.

Windows file sharing through SMB/CIFS is supported through shared directories.

Group-based SSL VPN bookmarks

The administrator can add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client. This can only be done via the CLI.

To add group-based SSL VPN bookmarks - CLI:

```
config vpn ssl web portal
  edit "portal-name"
    set user-group-bookmark enable*/disable
  next
end
config vpn ssl web user-group-bookmark
  edit "group-name"
    config bookmark
      edit "bookmark1"
        ....
      next
    end
  next
end
```

Downloading files from an SMB server in Web Mode

When logging into the SSL VPN in Web Mode, the client can connect to their file server via SMB and download multiple files at the same time. The client can select/deselect individual files for download, opt to download all, or select all checkboxes for download.

Split DNS support for SSL VPN portals

Split DNS for SSL VPN portals allows you to specify which domains are resolved by the DNS server specified by the VPN, while all other domains are resolved by the DNS specified locally. This feature is useful in both Enterprise and MSP scenarios (when hosting multiple SSL VPN portals).

FortiClient receives this information when the client connects in tunnel mode. FortiClient will push the DNS servers specified to the clients computer and all DNS requests will first attempt use this DNS server. The FortiClient network driver will intercept DNS requests; if they match the `split-dns-domains` listed, the DNS request will go across the tunnel and be resolved by the specified DNS servers.

If the domain does not match `split-dns-domains` then the FortiClient network driver will respond to the DNS request with "no such name" forcing the DNS request to be resolved by the physical adapter DNS.

To configure split DNS support for SSLVPN portals - CLI:

```

config vpn ssl web portal
  edit <name>
    config split-dns-domains
      edit <name>
        set domains "abc.com, cde.com"
        set dns-server1 192.168.1.1
        set dns-server2 192.168.1.2
        set ipv6-dns-server1 xxxxxxxxxxxx
        set ipv6-dns-server2 xxxxxxxxxxxx
      next
    ...
  end
end

```

Using the Bookmarks widget

The Bookmarks widget shows both administrator-configured and user-configured bookmarks. Administrator bookmarks cannot be altered but you can add, edit or delete user bookmarks.

The FortiGate unit forwards client requests to servers on the Internet or internal network. To use the web-portal applications, you add the URL, IP address, or name of the server application to the My Bookmarks list. For more information, see [Adding bookmarks on page 2692](#).

If you want to access a web server or telnet server without first adding a bookmark to the My Bookmarks list, use the Connection Tool instead. For more information, see [Using the Bookmarks widget on page 2692](#).

Adding bookmarks

You can add frequently used connections as bookmarks. Afterward, select any hyperlink from the Bookmarks list to initiate a session.

To add a bookmark

1. In the web portal, select **New Bookmark**.
2. Enter the following information:

Name	Enter the name to display in the Bookmarks list.
Type	Select the abbreviated name of the server application or network service from the drop-down list.
Location	Enter the IP address or FQDN of the server application or network service. For RDP connections, you can append some parameters to control screen size and keyboard layout. See Using the Bookmarks widget on page 2692 .
Description	Optionally enter a short description. The description displays when you pause the mouse pointer over the hyperlink.

SSO	<p>Single Sign On (SSO) is available for HTTP/HTTPS bookmarks only.</p> <p>Disabled — This is not an SSO bookmark.</p> <p>Automatic — Use your SSL VPN credentials or an alternate set. See the SSO Credentials field.</p> <p>Static — Supply credentials and other required information (such as an account number) to a web site that uses an HTML form for authentication. You provide a list of the form field names and the values to enter into them. This method does not work for sites that use HTTP authentication, in which the browser opens a pop-up dialog box requesting credentials.</p>
SSO fields	
SSO Credentials	<p>SSL VPN Login — Use your SSL VPN login credentials.</p> <p>Alternative — Enter Username and Password below.</p>
Username	Alternative username. Available if SSO Credentials is Alternative .
Password	Alternative password. Available if SSO Credentials is Alternative .
Static SSO fields	These fields are available if SSO is Static .
Field Name	Enter the field name, as it appears in the HTML form.
Value	<p>Enter the field value.</p> <p>To use the values from SSO Credentials, enter %passwd% for password or %username% for username.</p>
Add	Add another Field Name / Value pair.

3. Select **OK** and then select **Done**.

Group-based SSL VPN bookmarks

This CLI-only feature allows administrators to add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client.

Syntax:

```
config vpn ssl web portal
    edit "portal-name"
        set user-group-bookmark enable*/disable
    next
end
conf vpn ssl web user-group-bookmark
    edit "group-name"
        conf bookmark
            edit "bookmark1"
                ....
            next
        end
```

```
    next
end
```

Group-based SSL VPN bookmarks

This CLI-only feature allows administrators to add bookmarks for groups of users. SSL VPN will only output the matched group-name entry to the client.

Syntax:

```
config vpn ssl web portal
    edit <portal-name>
        set user-group-bookmark [enable | disable]
    next
end
config vpn ssl web user-group-bookmark
    edit <group-name>
        config bookmark
            edit <bookmark1>
                ....
            next
        end
    next
end
```

Automatic bookmarks for SSO credentials

The following CLI changes SSL VPN to send the basic authorization to the remote server for automatic SSO bookmark every time, but only if it is for the same host name. If this attribute is disabled, the SSO credentials are sent to the remote server for every HTTP request.

Syntax

```
config vpn ssl web user-bookmark
    edit <name>
        config bookmarks
            edit <name>
                set sso-credential-sent-once {enable | disable}
            next
        end
    next
end
```

Using the Quick Connection Tool

The **Quick Connection Tool** widget enables a user to connect to a resource when it isn't a predefined bookmark.

You can connect to any type of server without adding a bookmark to the **Bookmarks** list. The fields in the **Quick Connection Tool** enable you to specify the type of server and the URL or IP address of the host computer.

See the following procedures:

- [To connect to a web server on page 2695](#)
- [To ping a host or server behind the FortiGate unit on page 2695](#)

- To start a Telnet session on page 2695
- To start an FTP session on page 2696
- To start an SMB/CIFS session on page 2696
- To start an SSH session on page 2696
- To start an RDP session on page 2697
- To start a VNC session on page 2698

Except for ping, these services require that you have an account on the server to which you connect.

When you use **Quick Connection Tool**, the FortiGate unit may offer you its self-signed security certificate. Select **Yes** to proceed. A second message may be displayed to inform you of a host name mismatch. This message is displayed because the FortiGate unit is attempting to redirect your web browser connection. Select **Yes** to proceed.

To connect to a web server

1. In **Type**, select **HTTP/HTTPS**.
2. In the **Host** field, type the URL of the web server.
For example: `http://www.mywebexample.com` or `https://172.20.120.101`
3. Select **Launch**.
4. To end the session, close the browser window.

To ping a host or server behind the FortiGate unit

1. In **Type**, select **Ping**.
2. In the **Host** field, enter the IP address of the host or server that you want to reach.
For example: `10.11.101.22`
3. Select **Launch**.
A message stating whether the IP address can be reached or not is displayed.

To start a Telnet session

1. In **Type**, select **Telnet**.
2. In the **Host** field, type the IP address of the telnet host.
For example: `10.11.101.12`
3. Select **Launch**.
A Telnet window opens.
4. Select **Connect**.
5. A telnet session starts and you are prompted to log in to the remote host.
After you log in, you may enter any series of valid telnet commands at the system prompt.
6. To end the session, select **Disconnect** (or type `exit`) and then close the TELNET connection window.

To start an FTP session

1. In **Type**, select **FTP**.
2. In the **Host** field, type the IP address of the FTP server.
For example: 10.11.101.12
3. Select **Launch**.
A login window opens.
4. Enter your user name and password and then select **Login**.
You must have a user account on the remote host to log in.
5. Manipulate the files in any of the following ways:
 - To download a file, select the file link in the **Name** column.
 - To access a subdirectory (**Type** is **Folder**), select the link in the **Name** column.
 - To create a subdirectory in the current directory, select **New directory**.
 - To delete a file or subdirectory from the current directory, select its **Delete** icon.
 - To rename a file in the current directory, select its **Rename** icon.
 - To upload a file to the current directory from your client computer, select **Upload**.
 - When the current directory is a subdirectory, you can select **Up** to access the parent directory.
6. To end the FTP session, select **Logout**.

To start an SMB/CIFS session

1. In **Type**, select **SMB/CIFS**.
2. In the **Host** field, type the IP address of the SMB or CIFS server.
For example: 10.11.101.12
3. Select **Launch**.
4. Enter your user name and password and then select **Login**.
You must have a user account on the remote host to log in.
5. Manipulate the files in any of the following ways:
 - To download a file, select the file link in the **Name** column.
 - To access a subdirectory (**Type** is **Folder**), select the file link in the **Name** column.
 - To create a subdirectory in the current directory, select **New Directory**.
 - To delete a file or subdirectory from the current directory, select its **Delete** icon.
 - To rename a file, select its **Rename** icon.
 - To upload a file from your client computer to the current directory, select **Upload**.
 - When the current directory is a subdirectory, you can select **Up** to access the parent directory.
6. To end the SMB/CIFS session, select **Logout** and then close the SMB/CIFS window.

To start an SSH session

1. In **Type**, select **SSH**.
2. In the **Host** field, type the IP address of the SSH host.
For example: 10.11.101.12
3. Select **Launch**.
A login window opens.

4. Select **Connect**.

A SSH session starts and you are prompted to log in to the remote host. You must have a user account to log in. After you log in, you may enter any series of valid commands at the system prompt.

5. To end the session, select **Disconnect** (or type `exit`) and then close the SSH connection window.

To start an RDP session

1. In **Type**, select **RDP**.

2. In the **Host** field, type the IP address of the RDP host.

For example: `10.11.101.12`

3. Optionally, you can specify additional options for RDP by adding them to the **Host** field following the host address. See [RDP options on page 2697](#) for information about the available options.

For example, to use a French language keyboard layout you would add the `-m` parameter:

```
10.11.101.12 -m fr
```

4. To log in to the remote host, type your user name and password. You must have a user account on the remote host to log in. Note that the user name should be entered in User Principal Name (UPN) format.

5. Select **Launch**.

A login window opens.

6. When you see a screen configuration dialog, click **OK**.

The screen configuration dialog does not appear if you specified the screen resolution with the host address.

7. Select **Login**.

If you need to send Ctrl-Alt-Delete in your session, use Ctrl-Alt-End.

8. To end the RDP session, Log out of Windows or select **Cancel** from the Logon window.

Some Windows servers require a specific Security to be set for RDP sessions, such as Network Level Authentication (NLA) or Transport Layer Security (TLS), not the standard RDP encryption security. For example, Windows 10 requires the use of TLS.

RDP options

Locale/Keyboard	-m <locale>			
Use this option if the remote computer might not use the same keyboard layout as your computer. Select the locale code that matches your computer.	The supported values of <locale> are:			
	ar da de de-ch en-gb en-uk en-us es fi fr fr-be fr-ca fr-ch hr hu	Arabic Danish German Swiss German British English UK English US English Spanish Finnish French Belgian French Canadian French Swiss French Croatian Hungarian	it ja lt lv mk no pl pt pt-br ru sl sv tk tr	Italian Japanese Lithuanian Latvian Macedonian Norwegian Polish Portuguese Brazilian Portuguese Russian Slovenian Sudanese Turkmen Turkish

To start a VNC session

1. In **Type**, select **VNC**.
2. In the **Host** field, type the IP address of the VNC host.
For example: 10.11.101.12
3. Select **Launch**.
A login window opens.
4. Type your user name and password when prompted to log in to the remote host.
You must have a user account on the remote host to log in.
5. Select **OK**.
If you need to send Ctrl-Alt-Delete in your session, press F8, then select **Send Ctrl-Alt-Delete** from the pop-up menu.
6. To end the VNC session, close the VNC window.

Note that the RDP/VNC web portals are **not** supported for the following platforms:

Platform	Model
FortiGate	80D, 92D, 200D, 200D-POE, 240D, 240D-POE, 600C, 800C, 1000C, 3240C, 3600C, and 5001C
FortiGate-Rugged	90D
FortiWiFi	92D

Using FortiClient

Remote users can use FortiClient Endpoint Security to initiate an SSL VPN tunnel to connect to the internal network. FortiClient uses local port TCP 1024 to initiate an SSL encrypted connection to the FortiGate unit, on port TCP 10443. When connecting using FortiClient, the FortiGate unit authenticates the FortiClient SSL VPN request based on the user group options. the FortiGate unit establishes a tunnel with the client and assigns a virtual IP address to the client PC. Once the tunnel has been established, the user can access the network behind the FortiGate unit.

For information on configuring the FortiGate unit for SSL VPN connectivity, see [Basic configuration on page 2651](#). For details on configuring FortiClient for SSL VPN connections, see the FortiClient documentation.

Setup examples

The examples in this chapter demonstrate the basic configurations needed for common connections to the SSL VPN tunnel and portals, applying the steps outlined in [Basic configuration on page 2651](#).

The following examples are included:

Secure Internet browsing

This example sets up an SSL VPN tunnel that provides remote users the ability to access the Internet while traveling, and ensures that they are not subject to malware and other dangers, by using the corporate firewall to filter all of their Internet traffic. Essentially, the remote user will connect to the corporate FortiGate unit to surf the Internet.

Using SSL VPN and FortiClient SSL VPN software, you create a means to use the corporate FortiGate to browse the Internet safely.

Creating an SSL VPN IP pool and SSL VPN web portal

1. Go to **VPN > SSL-VPN Portals** and select *tunnel-access*.
2. Disable **Split Tunneling**.
3. For **Source IP Pools** select **SSLVPN_TUNNEL_ADDR1**.
4. Select **OK**.

Creating the SSL VPN user and user group

1. Create the SSL VPN user and add the user to a user group configured for SSL VPN use.
2. Go to **User & Device > User Definition** and select **Create New** to add the user:

User Name	twhite
Password	password

3. Select **OK**.
4. Go to **User & Device > User Groups** and select **Create New** to add *twhite* to a group called **SSL VPN**:

Name	SSL VPN
Type	Firewall

5. Move **twwhite** to the **Members** list.
6. Select **OK**.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1. Go to **Network > Static Routes** and select **Create New** to add the static route.

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

The **Destination IP/Mask** matches the network address of the remote SSL VPN user.

2. Select **OK**.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Add an SSL VPN security policy as below, and click **OK**.

Incoming Interface	ssl.root
Outgoing Interface	internal
Source Address	all
Source User Group	SSL VPN
Destination	all

3. Select **OK**.

Configuring authentication rules

1. Go to **VPN > SSL-VPN Settings** and select **Create New** under **Authentication/Portal Mapping**.
2. Add an authentication rule for the remote user:

Users/Groups	Tunnel
Portal	tunnel-access

3. Select **OK** and **Apply**.

Results

Using the FortiClient SSLVPN application, access the VPN using the address `https://172.20.120.136:443/` and log in as `twhite`. Once connected, you can browse the Internet.

From the FortiGate web-based manager, go to **Monitor > SSL-VPN Monitor** to view the list of users connected using SSL VPN. The **Subsession** entry indicates the split tunnel which redirects to the Internet.

Split tunnel

In this configuration, remote users are able to securely access the head office internal network through the head office firewall, yet browse the Internet without going through the head office FortiGate. Split tunneling is enabled by default for SSL VPN on FortiGate units.

The solution below describes how to configure FortiGate SSL VPN split tunneling using the FortiClient SSL VPN software, available from the [Fortinet Support site](#).

Without split tunneling, all communication from remote SSL VPN users to the head office internal network and to the Internet uses an SSL VPN tunnel between the user's PC and the head office FortiGate unit. Connections to the Internet are routed back out the head office FortiGate unit to the Internet. Replies come back into the head office FortiGate unit before being routed back through the SSL VPN tunnel to the remote user.

In short, enabling split tunneling protects the head office from potentially harmful access and external threats that may occur as a result of the end user's indiscretion while browsing the Internet. By contrast, disabling split tunneling protects the end user by forcing all their Internet traffic to pass through the FortiGate firewall.

Creating a firewall address for the head office server

1. Go to **Policy & Objects > Addresses** and select **Create New** and add the head office server address:

Category	Address
Name	Head office server
Type	Subnet
Subnet / IP Range	192.168.1.12
Interface	Internal

2. Select **OK**.

Creating an SSL VPN IP pool and SSL VPN web portal

1. Go to **VPN > SSL-VPN Portals** and select **tunnel-access**.
2. Enter the following:

Name	Connect to head office server
Enable Tunnel Mode	Enable

Enable Split Tunneling	Enable
Routing Address	Internal
Source IP Pools	SSLVPN_TUNNEL_ADDR1

3. Select **OK**.

Creating the SSL VPN user and user group

Create the SSL VPN user and add the user to a user group.

1. Go to **User & Device > User Definition**, select **Create New** and add the user:

User Name	twhite
Password	password

2. Select **OK**.
3. Go to **User & Device > User Groups** and select **Create New** to add the new user to the SSL VPN user group:

Name	Tunnel
Type	Firewall

4. Move **twhite** to the **Members** list.
5. Select **OK**.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1. Go to **Network > Static Routes** and select **Create New**

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

2. Select **OK**.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit. Create a normal security policy from ssl.root to wan1 to allow SSL VPN traffic to connect to the Internet.

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Complete the following:

Incoming Interface	ssl.root
---------------------------	----------

Source Address	all
Source User(s)	Tunnel
Outgoing Interface	internal
Destination Address	Head office server

3. Select **OK**.
4. Add a security policy that allows remote SSL VPN users to connect to the Internet.
5. Select **Create New**.
6. Complete the following and select **OK**:

Incoming Interface	ssl.root
Source Address	all
Source User(s)	Tunnel
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

Configuring authentication rules

1. Go to **VPN > SSL-VPN Settings** and select **Create New** under **Authentication/Portal Mapping**.
2. Add an authentication rule for the remote user:

Users/Groups	Tunnel
Portal	tunnel-access

3. Select **OK** and **Apply**.

Results

Using the FortiClient SSL VPN application on the remote PC, connect to the VPN using the address `https://172.20.120.136:443/` and log in with the `twhite` user account. Once connected, you can connect to the head office server or browse to web sites on the Internet.

From the web-based manager, go to **Monitor > SSL-VPN Monitor** to view the list of users connected using SSL VPN. The **Subsession** entry indicates the split tunnel which redirects SSL VPN sessions to the Internet.

Multiple user groups with different access permissions

You might need to provide access to several user groups with different access permissions. Consider the following example topology in which users on the Internet have controlled access to servers and workstations on private networks behind a FortiGate unit.

In this example configuration, there are two users:

- User1 can access the servers on Subnet_1.
- User2 can access the workstation PCs on Subnet_2.

You could easily add more users to either user group to provide them access to the user group's assigned web portal.

General configuration steps

1. Create firewall addresses for:
 - The destination networks.
 - Two non-overlapping tunnel IP address ranges that the FortiGate unit will assign to tunnel clients in the two user groups.
2. Create two web portals.
3. Create two user accounts, User1 and User2.
4. Create two user groups. For each group, add a user as a member and select a web portal. In this example, User1 will belong to Group1, which will be assigned to Portal1 (similar configuration for User2).
5. Create security policies:
 - Two SSL VPN security policies, one to each destination.
 - Two tunnel-mode policies to allow each group of users to reach its permitted destination network.
6. Create the static route to direct packets for the users to the tunnel.

Creating the firewall addresses

Security policies do not accept direct entry of IP addresses and address ranges. You must define firewall addresses in advance.

Creating the destination addresses

SSL VPN users in this example can access either Subnet_1 or Subnet_2.

To define destination addresses - web-based manager:

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	Subnet_1
Type	Subnet
Subnet/IP Range	10.11.101.0/24
Interface	port2

3. Select **Create New**, enter the following information, and select **OK**:

Name	Subnet_2
Type	Subnet
Subnet/IP Range	10.11.201.0/24
Interface	port3

Creating the tunnel client range addresses

To accommodate the two groups of users, split an otherwise unused subnet into two ranges. The tunnel client addresses must not conflict with each other or with other addresses.

To define tunnel client addresses - web-based manager:

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	Tunnel_group1
Type	IP Range
Subnet/IP Range	10.11.254.1-10.11.254.50
Interface	Any

3. Select **Create New**, enter the following information, and select **OK**.

Name	Tunnel_group2
Type	IP Range
Subnet/IP Range	10.11.254.51-10.11.254.100
Interface	Any

Creating the web portals

To accommodate two different sets of access permissions, you need to create two web portals, portal1 and portal2, for example. Later, you will create two SSL VPN user groups, one to assign to portal1 and the other to assign to portal2.

To create the portal1 web portal:

1. Go to **VPN > SSL-VPN Portals** and select **Create New**.
2. Enter `portal1` in the **Name** field.
3. In **Source IP Pools**, select **Tunnel_group1**.
4. Select **OK**.

To create the portal2 web portal:

1. Go to **VPN > SSL-VPN Portals** and select **Create New**.
2. Enter `portal2` in the **Name** field and select **OK**.
3. In **IP Pools**, select **Tunnel_group2**
4. Select **OK**.

Later, you can configure these portals with bookmarks and enable connection tool capabilities for the convenience of your users.

Creating the user accounts and user groups

After enabling SSL VPN and creating the web portals that you need, you need to create the user accounts and then the user groups that require SSL VPN access.

Go to **User & Device > User Definition** and create user1 and user2 with password authentication. After you create the users, create the SSL VPN user groups.

To create the user groups - web-based manager:

1. Go to **User & Device > User Groups**.
2. Select **Create New** and enter the following information:

Name	Group1
Type	Firewall

3. From the **Available** list, select **User1** and move it to the **Members** list by selecting the right arrow button.
4. Select **OK**.
5. Repeat steps 2 through 4 to create Group2, assigned to Portal2, with User2 as its only member.

Creating the security policies

You need to define security policies to permit your SSL VPN clients, web-mode or tunnel-mode, to connect to the protected networks behind the FortiGate unit. Before you create the security policies, you must define the source and destination addresses to include in the policy. See [Creating the firewall addresses on page 2704](#).

Two types of security policy are required:

- An SSL VPN policy enables clients to authenticate and permits a web-mode connection to the destination network. In this example, there are two destination networks, so there will be two SSL VPN policies. The authentication ensures that only authorized users can access the destination network.
- A tunnel-mode policy is a regular ACCEPT security policy that enables traffic to flow between the SSL VPN tunnel interface and the protected network. Tunnel-mode policies are required if you want to provide tunnel-mode connections for your clients. In this example, there are two destination networks, so there will be two tunnel-mode policies.

To create the SSL VPN security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information and click **OK**:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	All
Source User(s)	Group1
Outgoing Interface	port2
Destination Address	Subnet_1
Service	All

3. Select **Create New**.
4. Enter the following information:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	All
Source User(s)	Group2
Outgoing Interface	port3
Destination Address	Subnet_2
Service	All

5. Click **OK**.

Configuring authentication rules

1. Go to **VPN > SSL-VPN Settings** and select **Create New** under **Authentication/Portal Mapping**.
2. Add an authentication rule for the first remote group:

Users/Groups	Group1
Portal	Portal1

3. Select **OK** and **Apply**.
4. Select **Create New** and add an authentication rule for the second remote group:

Users/Groups	Group2
Portal	Portal2

5. Select **OK** and **Apply**.

To create the tunnel-mode security policies - web-based manager:

1. Go to **Policy & Objects > IPv4 Policy** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	Tunnel_group1
Source User(s)	Group1
Outgoing Interface	port2
Destination Address	Subnet_1
Service	All
Action	ACCEPT
Enable NAT	Enable

3. Select **Create New**.
4. Enter the following information, and select **OK**:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	Tunnel_group2
Source User(s)	Group2
Outgoing Interface	port3
Destination Address	Subnet_2
Service	All
Action	ACCEPT
Enable NAT	Enable

Create the static route to tunnel mode clients

Reply packets destined for tunnel mode clients must pass through the SSL VPN tunnel. You need to define a static route to allow this.

To add a route to SSL VPN tunnel mode clients - web-based manager:

1. Go to **Network > Static Routes** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	10.11.254.0/24 This IP address range covers both ranges that you assigned to SSL VPN tunnel-mode users. See Creating the tunnel client range addresses on page 2705 .
Device	Select the SSL VPN virtual interface, ssl.root for example.

In this example, the **IP Pools** field on the **VPN > SSL-VPN Settings** page is not used because each web portal specifies its own tunnel IP address range.

Client device certificate authentication with multiple groups

In the following example, we require clients connecting to a FortiGate SSL VPN to have a device certificate installed on their machine in order to authenticate to the VPN.

Employees (in a specific OU in AD) will be required to have a device certificate to connect, while vendors (in a separate OU in AD) will *not* be required to have a device certificate.

This can *only* be performed in the CLI console.

The Authentication-rule option is only available in the CLI as an advanced setting to achieve your requirements. It is not available on the GUI. So in **VPN > SSL-VPN Settings**, do *not* enable **Require Client Certificate**, but selectively enable `client-cert` in each authentication-rule based on the requirements through CLI instead.

Configuring SSL VPN shared settings and authentication rules - CLI:

The following example assumes that remote LDAP users/groups have been pre-configured.

```
config vpn ssl settings
  set servercert "Fortinet_Factory"
  set tunnel-ip-pools "SSLVPN_TUNNEL_ADDR1"
  set port 443
  set source-interface "wan1"
  set source-address "all"
  set default-portal "full-access"
  config authentication-rule
    edit 1
      set source-interface "wan1"
      set source-address "all"
      set groups "Employees"
      set portal "full-access"
      set client-cert enable
    next
    edit 2
      set source-interface "wan1"
      set source-address "all"
      set groups "Vendors"
      set portal "full-access"
      set client-cert disable <-- Set by default and will not be displayed.
    next
  end
end
```

Configure the remainder of the SSL VPN tunnel as normal (creating a firewall policy allowing SSL VPN access to the internal network, including the VPN groups, necessary security profiles, etc.).

If configured correctly, only the 'Employees' group should require a client certificate to authenticate to the VPN.

Troubleshooting

This section contains tips to help you with some common challenges of SSL VPNs, and other miscellaneous information useful for testing and troubleshooting.

- Enter the following to display debug messages for SSL VPN:

```
diagnose debug application sslvpn -1
```

This command enables debugging of SSL VPN with a debug level of -1. The -1 debug level produces detailed results.

- Enter the following command to verify the debug configuration:

```
diagnose debug info
debug output: disable
console timestamp: disable
console no user log message: disable
sslvpn debug level: -1 (0xffffffff)
CLI debug level: 3
```

This output verifies that SSL VPN debugging is enabled with a debug level of -1, and shows what filters are in place. The output above indicates that debug output is disabled, so debug messages are not displayed. The output also indicates that debugging has not been enabled for any software systems.

- Enter the following to enable displaying debug messages:

```
diagnose debug enable
```

To view the debug messages, log into the SSL VPN portal. The CLI displays debug output similar to the following:

```
FGT60C3G10002814 # [282:root]SSL state:before/accept initialization (172.20.120.12)
[282:root]SSL state:SSLv3 read client hello A (172.20.120.12)
[282:root]SSL state:SSLv3 write server hello A (172.20.120.12)
[282:root]SSL state:SSLv3 write change cipher spec A (172.20.120.12)
[282:root]SSL state:SSLv3 write finished B (172.20.120.12)
[282:root]SSL state:SSLv3 flush data (172.20.120.12)
[282:root]SSL state:SSLv3 read finished A:system lib(172.20.120.12)
[282:root]SSL state:SSLv3 read finished A (172.20.120.12)
[282:root]SSL state:SSL negotiation finished successfully (172.20.120.12)
[282:root]SSL established: DHE-RSA-AES256-SHA SSLv3 Kx=DH Au=RSA Enc=AES(256) Mac=SHA1
```

- Enter the following to stop displaying debug messages:

```
diagnose debug disable
```

The following is a list of potential issues. The suggestions below are not exhaustive, and may not reflect your network topology.

There is no response from the SSL VPN URL.

- Go to **VPN > SSL-VPN Settings** and check the SSL VPN port assignment. Also, verify that the SSL VPN policy is configured correctly.
- Check the URL you are attempting to connect to. It should follow this pattern:

```
https://<FortiGate IP>:<Port>/remote/login
```

- Ensure that you are using the correct port number in the URL.

FortiClient cannot connect.

Read the Release Notes to ensure that the version of FortiClient you are using is compatible with your version of FortiOS.

Tunnel-mode connection shuts down after a few seconds.

This issue can occur when there are multiple interfaces connected to the Internet (for example, a dual WAN). Upgrade to the latest firmware then use the following CLI command:

```
config vpn ssl settings
    set route-source-interface enable
end
```

When you attempt to connect using FortiClient or in Web mode, you are returned to the login page, or you receive the following error message: “Unable to logon to the server. Your user name or password may not be configured properly for this connection. (-12).”

- Ensure that cookies are enabled in your browser.
- If you are using a remote authentication server, ensure that the FortiGate is able to communicate with it.
- Access to the web portal or tunnel will fail if Internet Explorer has the privacy Internet Options set to High. If set to High, Internet Explorer will block cookies that do not have a compact privacy policy, and that use personally identifiable information without your explicit consent.

You receive an error message stating: “Destination address of Split Tunneling policy is invalid.”

The SSL VPN security policy uses the **ALL** address as its destination. Change the address to that of the protected network instead.

The tunnel connects but there is no communication.

Go to **Network > Static Routes** and ensure that there is a static route to direct packets destined for the tunnel users to the SSL VPN interface.

You can connect remotely to the VPN tunnel but are unable to access the network resources.

Go to **Policy & Objects > IPv4 Policy** and examine the policy allowing VPN access to the local network. If the destination address is set to all, create a firewall address for the internal network. Change the destination address and attempt to connect remotely again.

Users are unable to download the SSL VPN plugin.

Go to **VPN > SSL-VPN Portals** to make sure that the option to **Limit Users to One SSL-VPN Connection at a Time** is disabled. This allows users to connect to the resources on the portal page while also connecting to the VPN through FortiClient.

Users are being assigned to the wrong IP range.

Ensure that the same IP Pool is used in VPN Portal and VPN Settings to avoid conflicts. If there is a conflict, the portal settings will be used.

Flow-based (vdom) AntiVirus profiles in SSL VPN web mode limitation

In flow mode vdom, SSL VPN web mode doesn't block antivirus even when `av-profile` is set (however, SSL VPN tunnel mode AV profile does work).

Sending tunnel statistics to FortiAnalyzer

By default, logged events include tunnel-up and tunnel-down status events. Other events, by default, will appear in the FortiAnalyzer report as "No Data Available". More accurate results require logs with `action=tunnel-stats`, which is used in generating reports on the FortiAnalyzer (rather than the tunnel-up and tunnel-down event logs). The FortiGate does not, by default, send `tunnel-stats` information.

To allow VPN `tunnel-stats` to be sent to FortiAnalyzer, configure the FortiGate unit as follows using the CLI:

```
config system settings
    set vpn-stats-log ipsec ssl
    set vpn-stats-period 300
end
```

HTTP header information

The X-Content-Type-Options header is added to internal pages of SSL VPN to comport with PCI-DSS compatibility. Strict-Transport-Security is added to the HTTP header for the same reason.

Visibility of SSL VPN portal SSO credentials

The SSL VPN portal SSO feature sends passwords and usernames in clear text to the client in a javascript file. This feature sees the introduction of a new CLI command to control the visibility of these SSO credentials. Enable this command to prevent SSO credentials from being sent to the client.

Syntax

```
config vpn ssl web portal
    edit portal
        set hide-sso-credential {enable | disable}
    next
end
```

Chapter 24 - System Administration

This guide contains the following sections:

- [What's New in FortiOS 6.0](#) informs you about new system administration features in FortiOS 6.0.
- [Administrators](#) describes the tasks that can be done to add and secure administrative access to a FortiGate.
- [Monitoring](#) discusses the various methods of monitoring both your FortiGate and network traffic through a range of different tools available within FortiOS.
- [Replacement messages](#) explains how to view and customize replacement messages on your FortiGate.
- [Administration for schools](#) shares basic practices administrators in school systems can employ .
- [PPTP and L2TP](#) contains information on configuring PPTP and L2TP VPNs as well as PPTP passthrough.
- [Session helpers](#) explains how to use session helpers to analyze data in the packet bodies of some protocols and make adjustments to allow those protocols to send packets through the firewall.
- [Advanced concepts](#) describes more involved administrative topics to enhance network security and traffic efficiency.

What's new in FortiOS 6.0

The following list contains new system administration features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- [Updates to "Administrator profiles" on page 2714](#)
- ["Restrict local admin authentication when remote authentication server is running" on page 2721](#)
- ["FortiToken extension to comply with PCI 3.2" on page 2726](#)
- ["Multi-dimension tagging" on page 2779](#)

Administrators

By default, the FortiGate has a super administrator account, called `admin`, which can't be deleted. Additional administrators can be added for various functions, each with a unique user name, password, and set of access privileges.

The following sections explain how to add and secure administrative access to a FortiGate:

- [Administrator profiles](#)
- [Adding a local administrator](#)
- [LDAP authentication for administrators](#)
- [Other methods of administrator authentication](#)
- [Administrator logout](#)
- [Monitoring administrators](#)
- [Management access](#)
- [Security precautions](#)

Administrator profiles

Administrator profiles define what the administrator can do when logged into the FortiGate. When you set up an administrator account, you also assign an administrator profile dictating what the administrator sees. Depending on the nature of the administrator's work, access level or seniority, you can allow them to view and configure as much, or as little, as required.

super_admin profile

This profile has access to all components of FortiOS, including the ability to add and remove other system administrators. For certain administrative functions, such as backing up and restoring the configuration, `super_admin` access is required. To ensure that there is always a method to administer the FortiGate, the `super_admin` profile can't be deleted or modified.

Lower level administrator profiles can't backup or restore the FortiOS configuration.

The `super_admin` profile is used by the default `admin` account. We recommend that you add a password and rename this account once you have set up your FortiGate. In order to rename the default account, a second admin account is required. For more information, see ["Adding a local administrator" on page 2715](#).

Creating profiles

To configure administrator profiles, go to **System > Admin Profiles** and select **Create New**.

On the **New Admin Profile** page, select the access permissions for the admin profile you are creating. For example, you can configure a profile so that the administrator can only read/write **Firewall** configuration, which includes firewall policies, addresses, services, schedules, packet capture, and some other parts of the FortiGate.

configuration. Any other aspects of the FortiGate configuration, including VPNs and security profiles, would be hidden from this administrator.

Access control can also be set to **Custom** for some features. This allows for more granular control of administrator access. Using the **Firewall** example, you can set access to **Custom** and then select separate **Read/Write** privileges for **Policy**, **Address**, **Service**, and **Schedule**.

Administrator timeout override per access profile

You can configure administrator profiles to increase inactivity timeout and facilitate use of the GUI for central monitoring. This feature allows the `admintimeout` value, under `config system accprofile`, to be overridden per access profile.

Note that you can set this on a per-profile basis, to avoid the option from being unintentionally set globally.

CLI Syntax - Configure admin timeout

```
config system accprofile
edit <name>
    set admintimeout-override {enable | disable}
    set admintimeout <0-480> - (default = 10, 0 = unlimited)
next
end
```

Adding a local administrator

Only administrators with read-write privileges for **User & Device** can create a new administrator account.

To add an administrator - GUI

1. Go to **System > Administrators**.
2. Select **Create New > Administrator**.
3. Add a **Username** for the administrator.

Don't include the characters `<>()#"'` in the administrator's name. Using these characters in the administrator account name can result in a cross site scripting (XSS) vulnerability.

4. Set **Type** to **Local User**.
5. Enter the **Password** for the user. This may be a temporary password that the administrator can change later. Passwords can be up to 256 characters in length. For more information on passwords, see the [Passwords](#) discussion in the Getting Started chapter.
6. Determine if you need to enable security options: **SMS**, **Two-factor Authentication**, **Restrict login to trusted hosts**, **Restrict admin to guest account provisioning only**.
7. Select **OK**.

You can configure guest management administrator's through the GUI. To create the user group to be used for guest user accounts, go to [Managing Guest Access](#) in the [Authentication](#) chapter.

To add an administrator - CLI

```
config system admin
  edit <admin_name>
    set password <password>
    set accprofile <profile_name>
    set guest-auth {enable | disable}
    set user-groups <group-name>
  end
```

The CLI command `set user-groups` can only be used when `guest-auth` is set to `enable`.

LDAP authentication for administrators

Administrators can use remote authentication, such as LDAP, to connect to the FortiGate.

To do this, you must follow these three steps:

- configure the LDAP server
- add the LDAP server to a user group
- configure the administrator account

Configure the LDAP server

First set up the LDAP server as you normally would, and include a group to bind to.

To configure the LDAP server - GUI

1. Go to **User & Device > LDAP Servers** and select **Create New**.
2. Enter a **Name** for the server.
3. Enter the **Server IP** address or name.
4. Enter the **Common Name Identifier** and **Distinguished Name**.
5. Set the **Bind Type** to **Regular** and enter the **Username** and **Password**.
6. Select **OK**.

To configure the LDAP server - CLI

```
config user ldap
  edit <ldap_server_name>
    set server <server_ip>
    set cnid cn
    set dn DC=XYZ,DC=COM
    set type regular
    set user name CN=Administrator,CN=Users,DC=XYZ,DC=COM
    set password <password>
    set member-attr <group_binding>
  end
```

Add the LDAP server to a user group

Next, create a user group that will include the LDAP server that was created above.

To create a user group - GUI

1. Go to **User & Device > User Groups** and select **Create New**.
2. Enter a **Name** for the group.
3. In the section labeled **Remote groups**, select **Create New**.
4. Select the **Remote Server** from the drop-down list.
5. Select **OK**.

To create a user group - CLI

```
config user group
  edit <group_name>
    config match
      edit 1
        set server-name <LDAP_server>
        set group-name <group_name>
      end
    end
  end
```

Configure the administrator account

Now you can create a new administrator, where rather than entering a password, you will use the new user group and the wildcard option for authentication.

To create an administrator - GUI

1. Go to **System > Administrators** and select **Create New**.
2. In the **Administrator** field, enter the name for the administrator.
3. For **Type**, select **Match a user on a remote server group**.
4. Select the **User Group** created above from the drop-down list.
5. Select **Wildcard**. The Wildcard option allows for LDAP users to connect as this administrator.
6. Select an **Admin Profile**.
7. Select **OK**.

To create an administrator - CLI

```
config system admin
  edit <admin_name>
    set remote-auth enable
    set accprofile super_admin
    set wild card enable
    set remote-group ldap
  end
```

Other methods of administrator authentication

Admin accounts can use a variety of methods for authentication, including RADIUS, TACACS+, and PKI.

RADIUS authentication for administrators

If you want to use a RADIUS server to authenticate administrators, you must:

- configure the FortiGate to access the RADIUS server
- create the RADIUS user group
- configure an administrator to authenticate with a RADIUS server.

TACACS+ authentication for administrators

If you want to use a TACACS+ server to authenticate administrators, you must:

- configure the FortiGate to access the TACACS+ server
- create a TACACS+ user group
- configure an administrator to authenticate with a TACACS+ server.

PKI certificate authentication for administrators

To use PKI authentication for an administrator, you must:

- configure a PKI user
- create a PKI user group
- configure an administrator to authenticate with a PKI certificate.

Administrator lockout

By default, the FortiGate sets the number of password retries at three, allowing the administrator a maximum of three attempts to log into their account before locking the account for a set amount of time.

Both the number of attempts (`admin-lockout-threshold`) and the wait time before the administrator can try to enter a password again (`admin-lockout-duration`) can be configured within the CLI.

To configure the lockout options:

```
config system global
    set admin-lockout-threshold <failed_attempts>
    set admin-lockout-duration <seconds>
end
```

The default value of `admin-lockout-threshold` is 3 and the range of values is between 1 and 10. The `admin-lockout-duration` is set to 60 seconds by default and the range of values is between 1 and 4294967295 seconds.

Keep in mind that the higher the lockout threshold, the higher the risk that someone may be able to break into the FortiGate.

Example:

To set the `admin-lockout-threshold` to one attempt and the `admin-lockout-duration` to a five minute duration before the administrator can try to log in again, enter the commands:

```
config system global
    set admin-lockout-threshold 1
    set admin-lockout-duration 300
end
```

If the time span between the first failed login attempt and the `admin-lockout-threshold` failed login attempt is less than `admin-lockout-duration`, the lockout will be triggered.

Monitoring administrators

You can view the administrators logged in using the **System Information** widget on the Dashboard. The **Current Administrator** row that shows the administrator logged in and the total number of administrators logged in. Selecting **Details** displays the administrators, where they are logging in from and how (CLI, GUI) and when they logged in.

You are also able to monitor the activities the administrators perform on the FortiGate using the event logging. Event logs include a number of options to track configuration changes.

To set logging - GUI

1. Go to **Log & Report > Log Settings**.
2. Under **Event Logging**, select **Customize** and ensure **System activity event** is selected.
3. Select **Apply**.

To set logging - CLI

```
config log eventfilter
    set event enable
    set system enable
end
```

To view the logs go to **Log & Report > System Events**.

Management access

Management access defines how administrators are able to log on to the FortiGate. In NAT mode, access is configured for each of the FortiGate's interfaces, using the interface's IP to connect. In transparent mode, a single management IP address is configured to allow access.

Management access can be via HTTP, HTTPS, Telnet, or SSH sessions. HTTPS and SSH are preferred as they are more secure. The management computer must connect to an interface that permits management access and its IP address must be on the same network. If you are using VDOMs, an administrator who is restricted to a specific VDOM must use a computer that connects to an interface on that VDOM.

You can allow remote administration of the FortiGate; however, it is not recommended, since it could compromise the security of the FortiGate. If you require remote administration, the following precautions can be taken to improve the security of a FortiGate:

- Use secure administrator passwords.
- Change these passwords regularly.
- Enable two-factor authentication for administrators.
- Enable secure administrative access to this interface using only HTTPS or SSH.
- Use Trusted Hosts to limit where the remote access can originate from.
- Don't change the system idle timeout from the default value of 5 minutes.

Security precautions

One potential point of a security breach is at the management computer. Administrators who leave their workstations for a prolonged amount of time while staying logged into the GUI or CLI leave the firewall open to malicious intent.

When logging in using a local admin with the default or empty password, a warning prompt will appear upon login. Admins will be logged out if they have no permissions.

Restrict logins from trusted hosts

Setting up trusted hosts for an administrator limits the addresses from where they can log into FortiOS. The trusted hosts configuration applies to most forms of administrative access including HTTPS, SSH, and SNMP. When you identify a trusted host for an administrator account, FortiOS accepts that administrator's login only from one of the trusted hosts. A login, even with proper credentials, from a non-trusted host is dropped.

Even if you have configured trusted hosts, if you have enabled ping administrative access on a FortiGate interface, it will respond to ping requests from any IP address.

To identify trusted hosts, go to **System > Administrators**, edit the administrator account, enable **Restrict login to trusted hosts**, and add up to ten trusted host IP addresses.

To add two trusted hosts from the CLI:

```
config system admin
  edit <administrator-name>
    set trustedhost1 172.25.176.23 255.255.255.255
    set trustedhost2 172.25.177.0 255.255.255.0
  end
```

Trusted host IP addresses can identify individual hosts or subnets. Just like firewall policies, FortiOS searches through the list of trusted hosts in order and acts on the first match it finds. When you configure trusted hosts, start by adding specific addresses at the top of the list. Follow with more general IP addresses. You don't have to add addresses to all of the trusted hosts as long as all specific addresses are above all of the 0.0.0.0 0.0.0.0 addresses.

Prevent concurrent administrator sessions

Concurrent administrator sessions occur when multiple people concurrently access the FortiGate using the same administrator account. This is allowed by default. If you wish to prevent this behavior go to **System > Settings** and disable **Allow multiple concurrent sessions for each administrator**.

From the CLI:

```
config system global
  set admin-concurrent disable
end
```

Note, if you disable concurrent sessions for an administrator, you will be allowed only one session with the same username even if it is from the same IP.

Restrict local admin authentication when remote authentication server is running

The following command can be enabled so that whenever any remote server (TACACS, LDAP, or RADIUS) is up and running, any local admin authentication will be blocked. Local admins will be allowed access only if no remote server is detected.

Syntax:

```
config system global
    set admin-restrict-local {enable | disable} - (Default is set to disable)
end
```

Segregate administrative roles

To minimize the effect of an administrator causing errors to the FortiGate configuration and possibly jeopardizing the network, create individual administrative roles where none of the administrators have super_admin permissions. For example, one account is used solely to create security policies, another for users and groups, another for VPN, and so on.

SSH log in time out

You can take up to 120 seconds to log into the FortiGate when using SSH. You can use the following CLI command to reduce this time and enhance security:

```
config system global
    set admin-ssh-grace-time <number_of_seconds>
end
```

The range can be between 10 and 3600 seconds.

HTTPS redirect

When configuring the Administration Settings (found at **System > Settings**), you can also enable HTTP to **Redirect to HTTPS**. When enabled, if a administrator tries to connect to an interface using HTTP, this traffic will be automatically redirected to use HTTPS instead for a more secure connection.

Administrator log in disclaimers

FortiOS can display a disclaimer before or after logging into the GUI or CLI (or both). In either case the administrator must read and accept the disclaimer before they can proceed.

Use the following command to display a disclaimer before logging in:

```
config system global
    set pre-login-banner enable
end
```

Use the following command to display a disclaimer after logging in:

```
config system global
    set post-login-banner enable
end
```

You can customize the replacement messages for these disclaimers by going to **System > Replacement Messages**. Select **Extended View** to view and edit the **Administrator** replacement messages.

From the CLI:

```
config system replacemsg admin pre_admin-disclaimer-text
config system replacemsg admin post_admin-disclaimer-text
```

Disable the console interface

You can disable your FortiGate's console interface to prevent any unwanted login attempts:

```
config system console
    set login disable
end
```

Disable other interfaces

If any of the interfaces on the FortiGate aren't being used, disable traffic on that interface. This avoids someone plugging in network cables and potentially causing network bypass or loop issues.

To disable an interface - GUI

1. Go to **Network > Interfaces**.
2. Select the interface from the list and select **Edit**.
3. For **Administrative Access**, select **Down**.
4. Select **OK**.

To disable an interface - CLI

```
config system interface
    edit <interface_name>
        set status down
    end
```

Self-signed GUI certificates

For increased security, the self-sign certificate is the default GUI certificate, if the BIOS certificate is using SHA-1.

Monitoring

With network administration, the first step is installing and configuring the FortiGate to be the protector of the internal network. Once the system is running efficiently, the next step is to monitor the system and network traffic. When a threat or vulnerability is discovered, you can make configuration changes as necessary.

This chapter discusses the various methods of monitoring both the FortiGate and the network traffic through a range of different tools available within FortiOS.

This section includes the topics:

- [Dashboard](#)
- [sFlow](#)
- [Monitor menus](#)
- [Logging](#)
- [Alert email](#)
- [SNMP](#)
- [SNMP get command syntax](#)

Dashboard

The FortiOS dashboard provides real-time system information presented in a network operations center (NOC) view with a focus on alerts. By default, the dashboard displays key statistics for the FortiGate, such as memory and CPU status, port health, whether they are up or down and their throughput. Widgets are interactive. By clicking or hovering over most widgets, you can get additional information or follow links to other pages.

The dashboard and its widgets include:

- Multiple dashboard support.
- VDOM and global dashboards.
- Widget resize control.
- Notifications on the top header bar.

For more information, see the [Dashboard](#) discussion in the [Getting Started](#) chapter of the Handbook.

sFlow support

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiOS implements sFlow version 5.

sFlow uses packet sampling to monitor network traffic. The sFlow Agent captures packet information at defined intervals and sends them to an sFlow Collector for analysis, providing real-time data analysis. The information sent is only a sampling of the data for minimal impact on network throughput and performance.

The sFlow Agent is embedded in the FortiGate. Once configured, the FortiGate sends sFlow datagrams of the sampled traffic to the sFlow Collector, also called an sFlow Analyzer. The sFlow Collector receives the datagrams, and provides real-time analysis and graphing to indicate where potential traffic issues are occurring. sFlow Collector software is available from a number of third party software vendors.

sFlow data captures only a sampling of network traffic, not all traffic like the traffic logs on the FortiGate. Sampling works by the sFlow Agent looking at traffic packets when they arrive on an interface. A decision is made

whether the packet is dropped and allowed to be to its destination or if a copy is forwarded to the sFlow Collector. The sample used and its frequency are determined during configuration.

sFlow is not supported on virtual interfaces such as vdom link, ipsec, ssl.root or gre.

The sFlow datagram sent to the Collector contains the information:

- Packet header (e.g. MAC, IPv4, IPv6, IPX, AppleTalk, TCP, UDP, ICMP)
- Sample process parameters (rate, pool, etc.)
- Input/output ports
- Priority (802.1p and TOS)
- VLAN (802.1Q)
- Source/destination prefix
- Next hop address
- Source AS, Source Peer AS
- Destination AS Path
- Communities, local preference
- User IDs (TACACS/RADIUS) for source/destination
- URL associated with source/destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

sFlow agents can be added to any type of FortiGate interface. sFlow isn't supported on some virtual interfaces such as VDOM link, IPsec, gre, and ssl.root.

For more information on sFlow, Collector software and sFlow MIBs, visit www.sflow.org.

Configuration

sFlow configuration is available only in the CLI. Configuration requires two steps: enabling the sFlow Agent and configuring the interface for the sampling information.

To enable sFlow - CLI:

```
config system sflow
  set collector-ip <ip_address>
  set collector-port <port_number>
  set source-ip <ip_address>
end
```

The default port for sFlow is UDP 6343.

To configure in VDOM - CLI:

```
config system vdom-sflow
  set vdom-sflow enable
  set collector-ip <ip_address>
  set collector-port <port_number>
  set source-ip <ip_address>
end
```

To configure sFlow agents per interface - CLI:

```
config system interface
```

```
edit <interface_name>
    set sflow-sampler enable
    set sample-rate <every_n_packets>
    set sample-direction [tx | rx | both]
    set polling-interval <seconds>
next
end
```

Monitor menus

The **Monitor** menus enable you to view session and policy information and other activity occurring on your FortiGate unit. The monitors provide the details of user activity, traffic and policy usage to show live activity. Monitors are available for DHCP, routing, security policies, traffic shaping, load balancing, security features, VPN, users, and WiFi.

Logging

FortiOS provides a robust logging environment that enables you to monitor, store, and report traffic information and FortiGate events, including attempted log ins and hardware status. Depending on your requirements, you can log to a number of different hosts.

To configure logging in the web-based manager, go to **Log & Report > Log Settings**.

To configure logging in the CLI use the commands `config log <log_location>`.

For details on configuring logging see the [Logging and Reporting Guide](#).

If you will be using several FortiGate units, you can also use a FortiAnalyzer unit for logging. For more information, see the FortiAnalyzer Administration Guide.

Syslog server

An industry standard for collecting log messages, for off-site storage. In the web-based manager, you are able to send logs to a single syslog server, however in the CLI you can configure up to three syslog servers where you can also use multiple configuration options. For example, send traffic logs to one server, antivirus logs to another. The FortiGate unit sends Syslog traffic over UDP port 514. Note that if a secure tunnel is configured for communication to a FortiAnalyzer unit, then Syslog traffic will be sent over an IPsec connection, using UDP 500/4500, Protocol IP/50.

To configure a Syslog server in the web-based manager, go to **Log & Report > Log Settings**. In the CLI use the commands:

```
config log syslogd setting
    set status enable
    set server <IP address or FQDN of syslog server>
end
```

Further options are available when enabled to configure a different port, facility and server IP address.

For Syslog traffic, you can identify a specific port/IP address for logging traffic. Configuration of these services is performed in the CLI, using the command `set source-ip`. When configured, this becomes the dedicated port to send this traffic over.

For example, to set the source IP of a Syslog server to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config log syslogd setting
    set status enable
    set source-ip 192.168.4.5
end
```

FortiToken extension to comply with PCI 3.2

For FortiToken to be PCI 3.2 compliant, multi-factor authentication with FortiOS can be globally enforced for all login methods under `config system global`.

When `multi-factor-authentication` is set to `mandatory`, the system will collect and log each factor (username, password, and OTP) after authentication.

Note that even if a user is not configured with two-factor authentication, an empty OTP (or any OTP entered) will make second factor authentication pass.

Syntax:

```
config system global
    set multi-factor-authentication {optional | mandatory} - (Default is set to optional)
end
```

Alert email

As an administrator, you want to be certain you can respond quickly to issues occurring on your network or on the FortiGate unit. Alert emails provide an efficient and direct method of notifying an administrator of events. By configuring alert messages, you can define the threshold when a problem becomes critical and needs attention. When this threshold is reached, the FortiGate unit will send an email to one or more individuals, notifying them of the issue.

In the following example, the FortiGate unit is configured to send email to two administrators (admin1 and admin2) when multiple intrusions are detected every two minutes. The FortiGate unit has its own email address on the mail server.

To configure the email service

1. Go to **System > Advanced**.
2. In the **Email Service**, enable **Use Custom Email Server**, complete the following and select **Apply**:

SMTP Server	Enter the address or name of the email server. For example, <code>smtp.example.com</code> .
Default Reply To	Enter an email address to associate with the alert email. This field is optional. If you enter an email address here, it overrides the email address entered when configuring alert email in Log & Report > Email Alert Settings .
Authentication	Enable authentication if required by the email server.
Security mode	Choose between <i>None</i> , <i>SMTPS</i> or <i>STARTTLS</i>
Port	25

To configure alert email - GUI

1. Go to **Log & Report > Email Alert Settings**.
2. Enter the information:

Email from	fortigate@example.com
Email to	admin1@example.com
	admin2@example.com

3. For the **Interval Time**, enter 2.
4. Select **Intrusion Detected**.
5. Select **Apply**.

To configure alert email - CLI

```
config system email-server
  set port 25
  set server smtp.example.com
  set authenticate enable
  set username FortiGate
  set password *****
end
config alertemail setting
  set username fortigate@example.com
  set mailto1 admin1@example.com
  set mailto2 admin2@example.com
  set filter category
  set IPS-logs enable
end
```

SNMP

Simple Network Management Protocol (SNMP) enables you to monitor hardware on your network. You can configure the hardware, such as the FortiGate SNMP agent, to report system information and send traps (alarms or event messages) to SNMP managers. An SNMP manager, or host, is typically a computer running an application that can read the incoming trap and event messages from the agent and send out SNMP queries to the SNMP agents. A FortiManager unit can act as an SNMP manager to one or more FortiGate units. FortiOS supports SNMP using IPv4 and IPv6 addressing.

By using an SNMP manager, you can access SNMP traps and data from any FortiGate interface or VLAN subinterface configured for SNMP management access. Part of configuring an SNMP manager is to list it as a host in a community on the FortiGate unit it will be monitoring. Otherwise, the SNMP monitor will not receive any traps from that FortiGate unit or be able to query that unit.

The FortiGate SNMP implementation is read-only. SNMP v1, v2c, and v3 compliant SNMP managers have read-only access to FortiGate system information through queries and can receive trap messages from the FortiGate unit.

To monitor FortiGate system information and receive FortiGate traps, you must first compile the Fortinet and FortiGate Management Information Base (MIB) files. A MIB is a text file that describes a list of SNMP data

objects that are used by the SNMP manager. These MIBs provide information the SNMP manager needs to interpret the SNMP trap, event, and query messages sent by the FortiGate unit SNMP agent.

FortiGate core MIB files are available for download by going to **System > SNMP** and selecting the download link on the page.

The Fortinet implementation of SNMP includes support for most of RFC 2665 (Ethernet-like MIB) and most of RFC 1213 (MIB II). For more information, see “[Fortinet MIBs](#)”. RFC support for SNMP v3 includes Architecture for SNMP Frameworks (RFC 3411), and partial support of User-based Security Model (RFC 3414).

SNMP traps alert you to events that occur such as a full log disk or a virus detected.

SNMP fields contain information about the FortiGate unit, such as CPU usage percentage or the number of sessions. This information is useful for monitoring the condition of the unit on an ongoing basis and to provide more information when a trap occurs.

The FortiGate SNMP v3 implementation includes support for queries, traps, authentication, and privacy. Authentication and encryption are configured in the CLI. See the `system snmp user` command in the FortiGate CLI Reference.

New SNMP trap for bypass events

When bypass mode is enabled or disabled on FortiGate units that are equipped with bypass interfaces and support AMC modules, a new SNMP trap is generated and logs bypass events.

Implement SNMP support for NAT Session monitoring which includes new SNMP OIDs

FortiOS 5.6 implements a new feature providing SNMP support for NAT session monitoring. The resulting new SNMP object identifier (OID) is:

```
FORTINET-FORTIGATE-  
MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwIppools.fgFwIppTables.fgFwIppStatsTable.fgFwIppStatsEntry  
1.3.6.1.4.1.12356.101.5.3.2.1.1
```

Additionally, there are eight new items:

```
.fgFwIppStatsName .1  
.fgFwIppStatsType .2  
.fgFwIppStatsStartIp .3  
.fgFwIppStatsEndIp .4  
.fgFwIppStatsTotalSessions .5  
.fgFwIppStatsTcpSessions .6  
.fgFwIppStatsUdpSessions .7  
.fgFwIppStatsOtherSessions .8
```

SNMP configuration settings

Before a remote SNMP manager can connect to the FortiGate agent, you must configure one or more FortiGate interfaces to accept SNMP connections by going to **Network > Interfaces**. Select the interface and, in the **Administrative Access**, select **SNMP**.

For VDOMS, SNMP traps can only be sent on interfaces in the management VDOM. Traps cannot be sent over other interfaces outside the management VDOM.

To configure SNMP settings, go to **System > SNMP**.

SNMP Agent	Select to enable SNMP communication.
Description	Enter descriptive information about the FortiGate unit. The description can be up to 35 characters.
Location	Enter the physical location of the FortiGate unit. The system location description can be up to 35 characters long.
Contact	Enter the contact information for the person responsible for this FortiGate unit. The contact information can be up to 35 characters.
SNMP v1/v2c section To create a new SNMP community, see SNMP Community .	
Community Name	The name to identify the community.
Queries	Indicates whether queries protocols (v1 and v2c) are enabled or disabled. A green check mark indicates queries are enabled; a gray x indicates queries are disabled. If one query is disabled and another one enabled, there will still be a green check mark.
Traps	Indicates whether trap protocols (v1 and v2c) are enabled or disabled. A green check mark indicates traps are enabled; a gray x indicates traps are disabled. If one query is disabled and another one enabled, there will still be a green check mark.
Enable	Select the check box to enable or disable the community.
SNMP v3 section To create a new SNMP community, see SNMP Community page.	
User Name	The name of the SNMPv3 user
Security Level	The security level of the user
Notification Host	The IP address or addresses of the host
Queries	Indicates whether queries are enabled or disabled. A green check mark indicates queries are enabled; a gray x indicates queries are disabled
New SNMP Community page	
Community Name	Enter a name to identify the SNMP community
Hosts (section)	

IP Address	<p>Enter the IP address and Identify the SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.</p> <p>You can also set the IP address to 0.0.0.0 to so that any SNMP manager can use this SNMP community.</p>
Delete	Removes an SNMP manager from the list within the Hosts section
Add	Select to add a blank line to the Hosts list. You can add up to eight SNMP managers to a single community.
Queries (section)	
Protocol	The SNMP protocol. In the v1 row, this means that the settings are for SNMP v1. In the v2c row, this means that the settings are for SNMP v2c.
Port	<p>Enter the port number (161 by default) that the SNMP managers in this community use for SNMP v1 and SNMP v2c queries to receive configuration information from the FortiGate unit. Select the Enable check box to activate queries for each SNMP version.</p> <p>Note: The SNMP client software and the FortiGate unit must use the same port for queries.</p>
Enable	Select to enable that SNMP protocol.
Traps (section)	
Protocol	The SNMP protocol. In the v1 row, this means that the settings are for SNMP v1. In the v2c row, this means that the settings are for SNMP v2c.
Local	<p>Enter the remote port numbers (port 162 for each by default) that the FortiGate unit uses to send SNMP v1 or SNMP v2c traps to the SNMP managers in this community. Select the Enable check box to activate traps for each SNMP version.</p> <p>Note: The SNMP client software and the FortiGate unit must use the same port for traps.</p>
Remote	<p>Enter the remote port number (port 162 is default) that the FortiGate unit uses to send SNMP v1 or v2c traps to the SNMP managers in this community.</p> <p>Note: The SNMP client software and the FortiGate unit must use the same port for queries.</p>
Enable	Select to activate traps for each SNMP version.

SNMP Event	<p>Enable each SNMP event for which the FortiGate unit should send traps to the SNMP managers in this community.</p> <p>CPU Over usage traps sensitivity is slightly reduced, by spreading values out over 8 polling cycles. This prevents sharp spikes due to CPU intensive short-term events such as changing a policy.</p> <p>Power Supply Failure event trap is available only on some models.</p> <p>AMC interfaces enter bypass mode event trap is available only on models that support AMC modules.</p>
Enable	Select to enable the SNMP event.
Create New SNMP V3 User	
User Name	Enter the name of the user.
Security Level	Select the type of security level the user will have.
Notification Host	Enter the IP address of the notification host. If you want to add more than one host, after entering the IP address of the first host, select the plus sign to add another host.
Enable Query	Select to enable or disable the query. By default, the query is enabled.
Port	Enter the port number in the field.
Events	Select the SNMP events that will be associated with that user.

Gigabit interfaces

When determining the interface speed of a FortiGate unit with a 10G interface, the IF-MIB.ifSpeed may not return the correct value. IF-MIB.ifSpeed is a 32-bit gauge used to report interface speeds in bits/second and cannot convert to a 64-bit value. The 32-bit counter wrap the output too fast to be accurate.

In this case, you can use the value ifHighSpeed. It reports interface speeds in megabits/second. This ensures that 10Gb interfaces report the correct value.

SNMP agent

You need to first enter information and enable the FortiGate SNMP Agent. Enter information about the FortiGate unit to identify it so that when your SNMP manager receives traps from the FortiGate unit, you will know which unit sent the information.

To configure the SNMP agent - GUI

1. Go to **System > SNMP**.
2. Select **Enable** for the **SNMP Agent**.
3. Enter a descriptive name for the agent.
4. Enter the location of the FortiGate unit.

5. Enter a contact or administrator for the SNMP Agent or FortiGate unit.
6. Select **Apply**.

To configure SNMP agent - CLI

```
config system snmp sysinfo
  set status enable
  set contact-info <contact_information>
  set description <description_of_FortiGate>
  set location <FortiGate_location>
end
```

SNMP community

An SNMP community is a grouping of devices for network administration purposes. Within that SNMP community, devices can communicate by sending and receiving traps and other information. One device can belong to multiple communities, such as one administrator terminal monitoring both a firewall SNMP and a printer SNMP community.

Add SNMP communities to your FortiGate unit so that SNMP managers can connect to view system information and receive SNMP traps.

You can add up to three SNMP communities. Each community can have a different configuration for SNMP queries and traps. Each community can be configured to monitor the FortiGate unit for a different set of events. You can also add the IP addresses of up to 8 SNMP managers to each community.

When the FortiGate unit is in virtual domain mode, SNMP traps can only be sent on interfaces in the management virtual domain. Traps cannot be sent over other interfaces.

To add an SNMP v1/v2c community - GUI

1. Go to **System > SNMP**.
2. In the **SNMP v1/v2c** area, select **Create New**.
3. Enter a **Community Name**.
4. Enter the IP address and Identify the SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.
5. Select the interface if the SNMP manager is not on the same subnet as the FortiGate unit.
6. Enter the **Port** number that the SNMP managers in this community use for SNMP v1 and SNMP v2c queries to receive configuration information from the FortiGate unit. Select the **Enable** check box to activate queries for each SNMP version.
7. Enter the Local and Remote port numbers that the FortiGate unit uses to send SNMP v1 and SNMP v2c traps to the SNMP managers in this community.
8. Select the **Enable** check box to activate traps for each SNMP version.
9. Select **OK**.

To add an SNMP v1/v2c community - CLI

```
config system snmp community
  edit <index_number>
    set events <events_list>
    set name <community_name>
    set query-v1-port <port_number>
    set query-v1-status {enable | disable}
```

```

    set query-v2c-port <port_number>
    set query-v2c-status {enable | disable}
    set status {enable | disable}
    set trap-v1-lport <port_number>
    set trap-v1-rport <port_number>
    set trap-v1-status {enable | disable}
    set trap-v2c-lport <port_number>
    set trap-v2c-rport <port_number>
    set trap-v2c-status {enable | disable}
end

```

To add an SNMP v3 community - GUI

1. Go to **System > SNMP**.
2. In the **SNMP v3** area, select **Create New**.
3. Enter a **User Name**.
4. Select a **Security Level** and associated authorization algorithms.
5. Enter the IP address of the **Notification Host** SNMP managers that can use the settings in this SNMP community to monitor the FortiGate unit.
6. Enter the **Port** number that the SNMP managers in this community use to receive configuration information from the FortiGate unit. Select the **Enable** check box to activate queries for each SNMP version.
7. Select the **Enable** check box to activate traps.
8. Select **OK**.

To add an SNMP v3 community - CLI

```

config system snmp user
  edit <index_number>
    set security-level [auth-priv | auth-no-priv | no-auth-no-priv]
    set queries enable
    set query-port <port_number>
    set notify-hosts <ip_address>
    set events <event_selections>
end

```

Enabling on the interface

Before a remote SNMP manager can connect to the FortiGate agent, you must configure one or more FortiGate interfaces to accept SNMP connections.

To configure SNMP access - GUI

1. Go to **Network > Interfaces**.
2. Choose an interface that an SNMP manager connects to and select **Edit**.
3. In **Administrative Access**, select **SNMP**.
4. Select **OK**.

To configure SNMP access - CLI

```

config system interface
  edit <interface_name>
    set allowaccess snmp
end

```

If the interface you are configuring already has protocols that are allowed access, use the command `append allowaccess snmp` instead, or else the other protocols will be replaced. For more information, see Adding and removing options from lists.

Fortinet MIBs

The FortiGate SNMP agent supports Fortinet proprietary MIBs as well as standard RFC 1213 and RFC 2665 MIBs. RFC support includes support for the parts of RFC 2665 (Ethernet-like MIB) and the parts of RFC 1213 (MIB II) that apply to FortiGate unit configuration.

There are two MIB files for FortiGate units - the Fortinet MIB, and the FortiGate MIB. The Fortinet MIB contains traps, fields and information that is common to all Fortinet products. The FortiGate MIB contains traps, fields and information that is specific to FortiGate units. Each Fortinet product has its own MIB. If you use other Fortinet products you will need to download their MIB files as well. Both MIB files are used for FortiOS and FortiOS Carrier; there are no additional traps for the Carrier version of the operating system.

The Fortinet MIB and FortiGate MIB along with the two RFC MIBs are listed in tables in this section. To download the two FortiGate MIB files, visit the [Fortinet Support](#) website. The Fortinet MIB contains information for Fortinet products in general. the Fortinet FortiGate MIB includes the system information for the FortiGate and version of FortiOS. Both files are required for proper SNMP data collection.

To download the MIB files, go to **System > SNMP** and select a MIB link in the **FortiGate SNMP MIB** section.

Your SNMP manager may already include standard and private MIBs in a compiled database that is ready to use. You must add the Fortinet proprietary MIB to this database to have access to the Fortinet specific information.

There were major changes to the MIB files between FortiOS Carrier v3.0 and v4.0. You need to use the new MIBs for FortiOS Carrier v4.0 or you may mistakenly access the wrong traps and fields.

MIB files are updated for each version of FortiOS. When upgrading the firmware ensure that you updated the Fortinet FortiGate MIB file as well.

Fortinet MIBs

MIB file name or RFC	Description
FORTINET-CORE-MIB.mib	<p>The Fortinet MIB includes all system configuration information and trap information that is common to all Fortinet products.</p> <p>Your SNMP manager requires this information to monitor FortiGate unit configuration settings and receive traps from the FortiGate SNMP agent.</p>
FORTINET-FORTIGATE-MIB.mib	<p>The FortiGate MIB includes all system configuration information and trap information that is specific to FortiGate units.</p> <p>Your SNMP manager requires this information to monitor FortiGate configuration settings and receive traps from the FortiGate SNMP agent. FortiManager systems require this MIB to monitor FortiGate units.</p>

MIB file name or RFC	Description
RFC-1213 (MIB II)	<p>The FortiGate SNMP agent supports MIB II groups with these exceptions.</p> <ul style="list-style-type: none"> • No support for the EGP group from MIB II (RFC 1213, section 3.11 and 6.10). • Protocol statistics returned for MIB II groups (IP/ICMP/TCP/UDP/etc.) do not accurately capture all FortiGate traffic activity. More accurate information can be obtained from the information reported by the Fortinet MIB.
RFC-2665 (Ethernet-like MIB)	<p>The FortiGate SNMP agent supports Ethernet-like MIB information. FortiGate SNMP does not support for the dot3Tests and dot3Errors groups.</p>

SNMP improvements for dynamic routing include support for RFC 4750 OSPF Version 2 Management Information Base and RFC 5643 Management Information Base for OSPFv3. These changes add the capability of logging dynamic routing activity. Examples include sending OSPF routing events or changes to a syslog server or FortiAnalyzer or changes in neighborhood status.

Device detection for SNMP traps

This setting is related to the device detection feature. It allows SNMP traps to detect when a new device comes online. Within SNMP configurations there is a configurable timeout setting that periodically checks for the device. When a check determines that the device is present a trap is sent.

In the GUI, when configuring an SNMP object, one of the settings is a checkbox, under **SNMP Events** for **Device detected**.

To configure the SNMP object in the CLI use the following syntax:

```
config system snmp community
  edit <community ID number>
    set name <string>
    set events device-new
  end
```

In order to configure the idle timeout for the device, use the following syntax in the CLI:

```
config system global
  set device-idle-timeout <integer of time in seconds>
end
```

The time value for the field can be set from 30 to 31536000.

SNMP get command syntax

Normally, to get configuration and status information for a FortiGate unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> | <MIB_field>}
```

...where...

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is `public`.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself.

The `SNMP get` command gets firmware version running on the FortiGate unit. The community name is `public`. The IP address of the interface configured for SNMP management access is `10.10.10.1`. The firmware version MIB field is `fgSysVersion` and the OID for this MIB field is `1.3.6.1.4.1.12356.101.4.1.1`. The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgSysVersion.0
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.4.1.1.0
```

The OIDs and object names used in these examples are dependent on the version of MIB and are subject to change.

Replacement messages

The replacement message list in **System > Replacement Messages** enables you to view and customize replacement messages. Highlight the replacement messages you wish to edit and customize the message content to your requirements. Hit **Save** when done. If you do not see the message you want to edit, select the Extended View option (in the upper right-hand corner of the screen).

If you make a mistake, you can select the **Restore Default** to return to the original message and code base.

For connections requiring authentication, the FortiGate uses HTTP to send an authentication disclaimer page for the user to accept before a security policy is in effect. Therefore, you must initiate HTTP traffic first in order to trigger the authentication disclaimer page. Once the disclaimer is accepted, you can send whatever traffic is allowed by the security policy.

Replacement message images

You can add images to replacement messages to:

- Disclaimer pages
- Login pages
- Declined disclaimer pages
- Login failed page
- Login challenge pages
- Keepalive pages

Image embedding is also available to the endpoint NAC download portal and recommendation portal replacement messages, as well as HTTP replacement messages.

Supported image formats are GIF, JPEG, TIFF and PNG. The maximum file size supported is 6000 bytes.

Adding images to replacement messages

To upload an image for use in a message

1. Go to **System > Replacement Messages**.
2. Select **Manage Images** at the top of the page.
3. Select **Create New**.
4. Enter a **Name** for the image.
5. Select the **Content Type**.
6. Select **Browse** to locate the file and select **OK**.

The image that you include in a replacement message, must have the following html:

```
<img src=%%IMAGE: <config_image_name>%% size=<bytes> >
```

For example:

```
<img src=%%IMAGE: logo_hq%% size=4272>
```

Modifying replacement messages

Replacement messages can be modified to include a message or content that suits your organization.

Use the expand arrows to view the replacement message list for a given category. Messages are in HTML format. To change a replacement message, go to **System > Replacement Messages** and select the replacement message that you want to modify. At the bottom pane of the window, you can see the message on one side and the HTML code on the other side. The message view changes in real-time as you change the content.

A list of common replacement messages appears in the main window. To see the entire list and all categories of replacement messages, in the upper-right corner of the window, select **Extended View**.

Replacement message categories

Alert email replacement messages

The FortiGate unit adds the replacement messages listed in this category to alert email messages sent to administrators. If you enable the option **Send alert email for logs based on severity** in **Log & Report**, you control whether or not replacement messages are sent by alert email based on how you set the **Minimum log level**.

For more information on Alert emails, see the Monitoring chapter.

Authentication replacement messages

The FortiGate unit uses the text of the authentication replacement messages for various user authentication HTML pages that are displayed when a user is required to authenticate because a security policy includes at least one identity-based policy that requires firewall users to authenticate.

These replacement message pages are for authentication using HTTP and HTTPS. You cannot customize the firewall authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

Users see the authentication login page when they use a VPN or a security policy that requires authentication. You can customize this page in the same way as you modify other replacement messages.

There are some unique requirements for these replacement messages:

- The login page must be an HTML page containing a form with `ACTION="/"` and `METHOD="POST"`
- The form must contain the following hidden controls:
 - `<INPUT TYPE="hidden" NAME="%%MAGICID%%" VALUE="%%MAGICVAL%%">`
 - `<INPUT TYPE="hidden" NAME="%%STATEID%%" VALUE="%%STATEVAL%%">`
 - `<INPUT TYPE="hidden" NAME="%%REDIRID%%" VALUE="%%PROTURI%%">`
- The form must contain the following visible controls:
 - `<INPUT TYPE="text" NAME="%%USERNAMEID%%" size=25>`
 - `<INPUT TYPE="password" NAME="%%PASSWORDID%%" size=25>`

Example

The following is an example of a simple authentication page that meets the requirements listed above.

```
<HTML><HEAD><TITLE>Firewall Authentication</TITLE></HEAD>
  <BODY><H4>You must authenticate to use this service.</H4>
  <FORM ACTION="/" method="post">
    <INPUT NAME="%%MAGICID%%" VALUE="%%MAGICVAL%%" TYPE="hidden">
  <TABLE ALIGN="center" BGCOLOR="#00cccc" BORDER="0"
    CELLPADDING="15" CELLSPACING="0" WIDTH="320"><TBODY>
```

```
<TR><TH>Username:</TH>
  <TD><INPUT NAME="%%USERNAMEID%%" SIZE="25" TYPE="text"> </TD></TR>
<TR><TH>Password:</TH>
  <TD><INPUT NAME="%%PASSWORDID%%" SIZE="25" TYPE="password"> </TD></TR>
<TR><TD COLSPAN="2" ALIGN="center" BGCOLOR="#00cccc">
  <INPUT NAME="%%STATEID%%" VALUE="%%STATEVAL%%" TYPE="hidden">
    <INPUT NAME="%%REDIRID%%" VALUE="%%PROTURI%%" TYPE="hidden">
    <INPUT VALUE="Continue" TYPE="submit"> </TD></TR>
</TBODY></TABLE></FORM></BODY></HTML>
```

Captive Portal Default replacement messages

The Captive Portal Default replacement messages are used for wireless authentication only. You must have a VAP interface with the security set as captive portal to trigger these replacement messages.

Device Detection Portal replacement message

The FortiGate unit displays the replacement message when the FortiGate unit cannot determine the type of BYOD or handheld device is used to connect the network.

Email replacement messages

The FortiGate unit sends the mail replacement messages to email clients using IMAP, POP3, or SMTP when an event occurs such as antivirus blocking a file attached to an email that contains a virus. Email replacement messages are text messages.

If the FortiGate unit supports SSL content scanning and inspection these replacement messages can also be added to IMAPS, POP3S, and SMTPS email messages.

Endpoint Control replacement message

The FortiGate unit displays the replacement message when the FortiClient Endpoint Security software is not installed or registered correctly with the FortiGate unit.

FortiGuard Web Filtering replacement messages

The FortiGate unit sends the FortiGuard Web Filtering replacement messages to web browsers using the HTTP protocol when FortiGuard web filtering blocks a URL, provides details about blocked HTTP 4xx and 5xx errors, and for FortiGuard overrides. FortiGuard Web Filtering replacement messages are HTTP pages.

If the FortiGate unit supports SSL content scanning and inspection and if **Protocol Recognition > HTTPS Content Filtering Mode** is set to Deep Scan in the antivirus profile, these replacement messages can also replace web pages downloaded using the HTTPS protocol.

FTP replacement messages

The FortiGate unit sends the FTP replacement messages listed in the table below to FTP clients when an event occurs such as antivirus blocking a file that contains a virus in an FTP session. FTP replacement messages are text messages.

HTTP replacement messages

The FortiGate unit sends the HTTP replacement messages listed in the following table to web browsers using the HTTP protocol when an event occurs such as antivirus blocking a file that contains a virus in an HTTP session.

HTTP replacement messages are HTML pages.

If the FortiGate unit supports SSL content scanning and inspection, and if under HTTPS in the protocol option list has Enable Deep Scan enabled, these replacement messages can also replace web pages downloaded using the HTTPS protocol.

NNTP replacement messages

The FortiGate unit sends the NNTP replacement messages NNTP clients when an event occurs such as antivirus blocking a file attached to an NNTP message that contains a virus. NNTP replacement messages are text messages.

Spam replacement messages

The FortiGate unit adds the Spam replacement messages to SMTP server responses if the email message is identified as spam and the spam action is discard. If the FortiGate unit supports SSL content scanning and inspection these replacement messages can also be added to SMTPS server responses.

NAC quarantine replacement messages

The page that is displayed for the user depends on whether NAC quarantine blocked the user because a virus was found, a DoS sensor detected an attack, an IPS sensor detected an attack, or a DLP rule with action set to **Quarantine IP address** or **Quarantine Interface** matched a session from the user.

The default messages inform the user of why they are seeing this page and recommend they contact the system administrator. You can customize the pages as required, for example to include an email address or other contact information or if applicable a note about how long the user can expect to be blocked.

SSL VPN replacement messages

The SSL VPN login replacement message is an HTML replacement message that formats the FortiGate SSL VPN portal login page. You can customize this replacement message according to your organization's needs. The page is linked to FortiGate functionality and you must construct it according to the following guidelines to ensure that it will work.

- The login page must be an HTML page containing a form with `ACTION="%%SSL_ACT%%"` and `METHOD="%%SSL_METHOD%%"`
- The form must contain the `%%SSL_LOGIN%%` tag to provide the login form.
- The form must contain the `%%SSL_HIDDEN%%` tag.

Web Proxy replacement messages

The FortiGate unit sends Web Proxy replacement messages when a web proxy event occurs that is detected and matches the web proxy configuration. These replacement messages are web pages that appear within your web browser.

The following web proxy replacement messages require an identity-based security policy so that the web proxy is successful. You can also enable FTP-over-HTTP by selecting the **FTP** option in **System > Network > Explicit Proxy**.

Traffic quota control replacement messages

When user traffic is going through the FortiGate unit and it is blocked by traffic shaping quota controls, users see the **Traffic shaper block message** or the **Per IP traffic shaper block message** when they attempt to connect through the FortiGate unit using HTTP.

The traffic quota HTTP pages should contain the `%%QUOTA_INFO%%` tag to display information about the traffic shaping quota setting that is blocking the user.

MM1 replacement messages

MM1 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

You must have **Remove Blocked** selected within the MMS profile if you want to remove the content that is intercepted during MMS scanning on the FortiGate unit.

MM3 replacement messages

MM3 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

You must have **Remove Blocked** selected within the MMS profile if you want to remove the content that is intercepted during MMS scanning on the unit.

MM4 replacement messages

MM4 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

MM7 replacement messages

MM7 replacement messages are sent when, during MMS content scanning, FortiOS Carrier detects, for example a virus, using the MMS profile.

MMS replacement messages

The MMS replacement message is sent when a section of an MMS message has been replaced because it contains a blocked file. This replacement message is in HTML format.

The message text is:

```
<HTML><BODY>This section of the message has been replaced because it contained a blocked
file</BODY></HTML>
```

Replacement message groups

Replacement message groups enable you to view common messages in groups for large carriers. Message groups can be configured by going to **Config > Replacement Message Group**.

Using the defined groups, you can manage specific replacement messages from a single location, rather than searching through the entire replacement message list.

If you enable virtual domains (VDOMs) on the FortiGate unit, replacement message groups are configured separately for each virtual domain. Each virtual domain has its own default replacement message group, configured from **System > Replacement Messages Group**.

When you modify a message in a replacement message group, a Reset icon appears beside the message in the group. You can select this Reset icon to reset the message in the replacement message group to the default version.

All MM1/4/7 notification messages for FortiOS Carrier (and MM1 retrieve-conf messages) can contain a SMIL layer and all MM4 notification messages can contain an HTML layer in the message. These layers can be used to brand messages by using logos uploaded to the FortiGate unit via the 'Manage Images' link found on the replacement message group configuration page.

Administration for schools

For a system administrator in a school system, it is difficult to maintain a network and access to the Internet. There are potential legal liabilities if content is not properly filtered and students gain access to pornography and other non-productive and potentially dangerous content. This section describes some basic practices administrators can employ.

Security policies

The default security policies in FortiOS allow all traffic on all ports and all IP addresses. While applying security profiles can help to block viruses, detect attacks and prevent spam, this doesn't provide a solid overall security option. The best approach is a layered approach; the first layer being the security policy.

When creating outbound security policies, you need to identify what the students are allowed to do. Generally, they surf the web, connect to FTP sites, send and receive email, and so on.

Once you know what the students need to do, you can research the software used and determine the ports the applications use. For example, if the students only require web surfing, then there are only two ports (80 - HTTP and 443 - HTTPS) needed to complete their tasks. Setting the security policies to only allow traffic through two ports (rather than all 65,000), this will significantly lower any possible exploits. By restricting the ports to known services, means stopping the use of proxy servers, as many of them operate on a non-standard port to hide their traffic from URL filtering or HTTP inspection.

DNS

You should restrict the students use of DNS. We recommend that you point to an internal DNS server and only allow those devices out on port 53.

If there is no internal DNS server, then you should establish a restrictive list of allowed DNS servers students can use. One possible exploit would be for them to set up their own DNS server at home that serves different IPs for known hosts, such as having Google.com sent back the IP for playboy.com.

Encrypted traffic (HTTPS)

Generally speaking, students should not be allowed to access encrypted web sites. Encrypted traffic can't be sniffed, and therefore, can't be monitored. HTTPS traffic should only be allowed when necessary. Most web sites a student needs to access are HTTP, not HTTPS. Due to the nature of HTTPS protocol, and the fact that encryption is an inherent security risk to your network, its use should be restricted.

To ensure that students only visit HTTPS sites required for schoolwork, we recommend that you add a security policy that designates a list of allowed secure sites.

FTP

For the most part, students should not be using FTP. FTP is not HTTP or HTTPS so you can't use URL filtering to restrict where they go. This can be controlled with destination IPs in the security policy. With a policy that specifically outlines which FTP addresses are allowed, all other will be blocked.

Example security policies

Given these recommended practices, a set of security policies could look like the following illustration. In a large setup, all the IPs for the students are treated by one of these four policies.

Simple security policy setup

ID	Name	From	To	Source	Destination	Schedule	Service	Action	Status
2	restrict https	internal	wan1	all Students	Allowed Websites	always	HTTPS	✓ ACCEPT	✓ Enabled
3	all http	internal	wan1	all Students	all	always	HTTP	✓ ACCEPT	✓ Enabled
4	allowed dns	internal	wan1	all Students	Allowed DNS	always	DNS	✓ ACCEPT	✓ Enabled
5	allowed ftp	internal	wan1	all Students	Allowed FTP	always	FTP	✓ ACCEPT	✓ Enabled
0	Implicit Deny	any	any	all	all	always	ALL	✗ DENY	

The last policy in the list is the deny policy that is configured by default. The deny policy ensures that any traffic making it to this point is stopped. It can also help in further troubleshooting by viewing the logs for denied traffic.

With these policies in place, even before packet inspection occurs, the FortiGate, and the network are fairly secure. Should any of the UTM profiles fail, there is still a basic level of security.

Security profiles

AntiVirus profiles

You should enable antivirus screening for any service that is enabled in the security policies. In the case above, HTTP, FTP, as well as POP3 and SMTP (assuming there is email access for students). There is not a virus scan option for HTTPS, because the content is encrypted. Generally speaking, most of the network traffic will be students surfing the web.

To configure antivirus profiles in the GUI, go to Security Profiles > AntiVirus.

Web filtering

You should configure your FortiGate to filter of URLs, sites and content, should be performed by FortiGuard. It is easier for the network administrator. Web sites are constantly being monitored, and new ones reviewed and added to the FortiGuard databases every day. The FortiGuard categories provide an extensive list of offensive and non-productive sites.

There are additional settings to include in a web filtering profile to best contain a student's web browsing.

- Web URL filtering should be enabled to set up exemptions for web sites that are blocked or reasons other than category filtering. It also prevents the use of IP addresses to get around web filtering.
- Block invalid URLs - HTTPS only. This option inspects the HTTPS certificate and looks at the URL to ensure it's valid. It is common for proxy sites to create an HTTPS certificate with a garbage URL. If the site is legitimate, it should be set up correctly. If the site approach to security is to ignore it, then their security policy puts your network at risk and the site should be blocked.

- Enable **Block malicious URLs discovered by FortiSandbox**. If the FortiSandbox discovers a threat, the source URL will be added to the list of URLs to be blocked by the FortiGate.

To configure web filtering options, go to **Security Profiles > Web Filter**.

Categories and classifications

For the selection of what FortiGuard categories and classifications that should be blocked, that is purely based on the school system and its Internet information policy.

Email filtering

Other than specific teacher-led email inboxes, there is no reason why a student should be able to access, read or send personal email. Ports for POP3, SMTP and IMAP should not be opened in a security policies.

IPS

The intrusion prevention profiles are used to ensure the student PCs are not vulnerable to attacks and are not in a position to make attacks. As well, IPS can do more than simple vulnerability scans. With a FortiGuard subscription, IPS signatures are pushed to the FortiGate unit. New signatures are released constantly for various intrusions as they are discovered.

FortiOS includes a number of predefined IPS sensors that you can enable by default. To configure IPS sensors, go to **Security Profiles > Intrusion Prevention**.

Application control

Application control uses IPS signatures to limit the use of instant messaging and peer-to-peer applications which can lead to possible infections on a student's PC. FortiOS includes a number of pre-defined application categories. To configure and maintain application control profiles, go to **Security Profiles > Application Control**.

Some applications to consider include proxies, botnets, toolbars and P2P applications.

Logging

Turn on all logging. Every option in this section should be enabled. This is not where you decide what you are going to log. You are identifying what the profiles can log.

Logging everything is a way to monitor traffic on the network, see what student's are utilizing the most, and locate any potential holes in your security plan. Keeping this information may help to prove negligence later if necessary.

PPTP and L2TP

A virtual private network (VPN) is a way to use a public network, such as the Internet, as a vehicle to provide remote offices or individual users with secure access to private networks. FortiOS supports the Point-to-Point Tunneling Protocol (PPTP), which enables interoperability between FortiGate units and Windows or Linux PPTP clients. Because FortiGate units support industry standard PPTP VPN technologies, you can configure a PPTP VPN between a FortiGate unit and most third-party PPTP VPN peers.

This section describes how to configure PPTP and L2TP VPNs as well as PPTP passthrough.

This section includes the topics:

- [How PPTP VPNs work](#)
- [FortiGate unit as a PPTP server](#)
- [Configuring the FortiGate unit for PPTP VPN](#)
- [Configuring the FortiGate unit for PPTP pass through](#)
- [Testing PPTP VPN connections](#)
- [Logging VPN events](#)
- [Configuring L2TP VPNs](#)
- [L2TP configuration overview](#)

How PPTP VPNs work

The Point-to-Point Tunneling Protocol enables you to create a VPN between a remote client and your internal network. Because it is a Microsoft Windows standard, PPTP does not require third-party software on the client computer. As long as the ISP supports PPTP on its servers, you can create a secure connection by making relatively simple configuration changes to the client computer and the FortiGate unit.

PPTP uses Point-to-Point protocol (PPP) authentication protocols so that standard PPP software can operate on tunneled PPP links. PPTP packages data in PPP packets and then encapsulates the PPP packets within IP packets for transmission through a VPN tunnel.

When the FortiGate unit acts as a PPTP server, a PPTP session and tunnel is created as soon as the PPTP client connects to the FortiGate unit. More than one PPTP session can be supported on the same tunnel. FortiGate units support PAP, CHAP, and plain text authentication. PPTP clients are authenticated as members of a user group.

Traffic from one PPTP peer is encrypted using PPP before it is encapsulated using Generic Routing Encapsulation (GRE) and routed to the other PPTP peer through an ISP network. PPP packets from the remote client are addressed to a computer on the private network behind the FortiGate unit. PPTP packets from the remote client are addressed to the public interface of the FortiGate unit. See the figure below.

PPTP control channel messages are not authenticated, and their integrity is not protected. Furthermore, encapsulated PPP packets are not cryptographically protected and may be read or modified unless appropriate encryption software such as Secure Shell (SSH) or Secure File Transfer Protocol (SFTP) is used to transfer data after the tunnel is established.

As an alternative, you can use encryption software such as Microsoft Point-to-Point Encryption (MPPE) to secure the channel. MPPE is built into Microsoft Windows clients and can be installed on Linux clients. FortiGate units support MPPE.

Packet encapsulation

Shown above, traffic from the remote client is addressed to a computer on the network behind the FortiGate unit. When the PPTP tunnel is established, packets from the remote client are encapsulated and addressed to the FortiGate unit. The FortiGate unit forwards disassembled packets to the computer on the internal network.

When the remote PPTP client connects, the FortiGate unit assigns an IP address from a reserved range of IP addresses to the client PPTP interface. The PPTP client uses the assigned IP address as its source address for the duration of the connection.

When the FortiGate unit receives a PPTP packet, the unit disassembles the PPTP packet and forwards the packet to the correct computer on the internal network. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely.

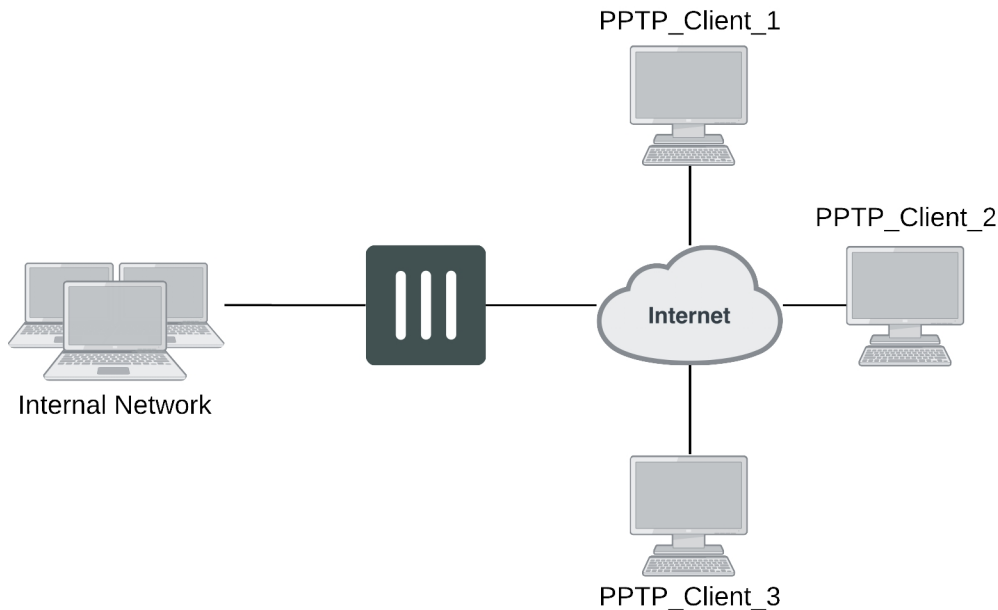

PPTP clients must be authenticated before a tunnel is established. The authentication process relies on FortiGate user group definitions, which can optionally use established authentication mechanisms such as RADIUS or LDAP to authenticate PPTP clients. All PPTP clients are challenged when a connection attempt is made.

FortiGate unit as a PPTP server

In the most common Internet scenario, the PPTP client connects to an ISP that offers PPP connections with dynamically-assigned IP addresses. The ISP forwards PPTP packets to the Internet, where they are routed to the FortiGate unit.

FortiGate unit as a PPTP server

If the FortiGate unit will act as a PPTP server, there are a number of steps to complete:

- Configure user authentication for PPTP clients.
- Enable PPTP.
- Specify the range of addresses that are assigned to PPTP clients when connecting
- Configure the security policy.

Configuring user authentication for PPTP clients

To enable authentication for PPTP clients, you must create user accounts and a user group to identify the PPTP clients that need access to the network behind the FortiGate unit. Within the user group, you must add a user for each PPTP client.

You can choose to use a plain text password for authentication or forward authentication requests to an external RADIUS, LDAP, or TACACS+ server. If password protection will be provided through a RADIUS, LDAP, or TACACS+ server, you must configure the FortiGate unit to forward authentication requests to the authentication server.

This example creates a basic user/password combination.

Configuring a user account

To add a local user - GUI

1. Go to **User & Device > User Definition** and select **Create New**.
2. Select **Local User**
3. Enter a **User Name**.
4. Enter a **Password** for the user. The password should be at least six characters.
5. Select **OK**.

To add a local user - CLI

```
config user local
  edit <username>
    set type password
    set passwd <password>
  end
```

Configuring a user group

To ease configuration, create user groups that contain users in similar categories or departments.

To create a user group - GUI

1. Go to **User & Device > User Group** and select **Create New**.
2. Enter a **Name** for the group.
3. Select the **Type** of **Firewall**.
4. From the **Available Users** list, select the required users and select the right-facing arrow to add them to the **Members** list.
5. Select **OK**.

To create a user group - CLI

```
config user group
  edit <group_name>
    set group-type firewall
    set member <user_names>
  end
```

Enabling PPTP and specifying the PPTP IP address range

The PPTP address range specifies the range of addresses reserved for remote PPTP clients. When a PPTP client connects to the FortiGate unit, the client is assigned an IP address from this range. Afterward, the FortiGate unit uses the assigned address to communicate with the PPTP client.

The address range that you reserve can be associated with private or routable IP addresses. If you specify a private address range that matches a network behind the FortiGate unit, the assigned address will make the PPTP client appear to be part of the internal network.

PPTP requires two IP addresses, one for each end of the tunnel. The PPTP address range is the range of addresses reserved for remote PPTP clients. When the remote PPTP client establishes a connection, the

FortiGate unit assigns an IP address from the reserved range of IP addresses to the client PPTP interface or retrieves the assigned IP address from the PPTP user group. If you use the PPTP user group, you must also define the FortiGate end of the tunnel by entering the IP address of the unit in **Local IP** (web-based manager) **or** `local-ip` (CLI). The PPTP client uses the assigned IP address as its source address for the duration of the connection.

PPTP configuration is only available through the CLI. In the example below, PPTP is enabled with the use of an IP range of 192.168.1.1 to 192.168.1.10 for addressing and the user group is `hr_staff`.

FortiOS 5.4.0 and later versions allow the start and end IPs in the PPTP address range to be in the same 16-bit subnet. Earlier versions require that the start and end IPs in the PPTP address range be in the same 24-bit subnet, for example, 192.168.1.1 - 192.168.1.254. .

```
config vpn pptp
  set status enable
  set ip-mode range
  set eip 192.168.1.10
  set sip 192.168.1.1
  set usrgrp hr_staff
end
```

In this example, PPTP is enabled with the use of a user group for addressing, where the IP address of the PPTP server is 192.168.1.2 and the user group is `hr_admin`.

```
config vpn pptp
  set status enable
  set ip-mode range
  set local-ip 192.168.2.1
  set usrgrp hr_admin
end
```

Adding the security policy

The security policy specifies the source and destination addresses that can generate traffic inside the PPTP tunnel and defines the scope of services permitted through the tunnel. If a selection of services are required, define a service group.

To configure the firewall for the PPTP tunnel - GUI

1. Go to **Policy & Objects > IPv4** or **Policy & Objects > IPv6** and select **Create New**.
2. Complete the following and select **OK**:

Incoming Interface	The FortiGate interface connected to the Internet.
Source Address	Select the name that corresponds to the range of addresses that you reserved for PPTP clients.
Outgoing Interface	The FortiGate interface connected to the internal network.
Destination Address	Select the name that corresponds to the IP addresses behind the FortiGate unit.

Schedule	always
Service	ALL
Action	ACCEPT

To configure the firewall for the PPTP tunnel - CLI

```
config firewall policy or config firewall policy6
edit 1
    set srcintf <interface to internet>
    set dstintf <interface to internal network>
    set srcaddr <reserved_range>
    set dstaddr <internal_addresses>
    set action accept
    set schedule always
    set service ALL
end
```

Configuring the FortiGate unit for PPTP VPN

To arrange for PPTP packets to pass through the FortiGate unit to an external PPTP server, perform the following tasks in the order given:

- Configure user authentication for PPTP clients.
- Enable PPTP on the FortiGate unit and specify the range of addresses that can be assigned to PPTP clients when they connect.
- Configure PPTP pass through on the FortiGate unit.

Configuring the FortiGate unit for PPTP passthrough

To forward PPTP packets to a PPTP server on the network behind the FortiGate unit, you need to perform the following configuration tasks on the FortiGate unit:

- Define a virtual IP address that points to the PPTP server.
- Create a security policy that allows incoming PPTP packets to pass through to the PPTP server.

The address range is the external (public) ip address range which requires access to the internal PPTP server through the FortiGate virtual port-forwarding firewall.

IP addresses used in this document are fictional and follow the technical documentation guidelines specific to Fortinet. Real external IP addresses are not used.

Configuring a virtual IP address

The virtual IP address will be the address of the PPTP server host.

To define a virtual IP for PPTP passthrough - GUI

1. Go to **Policy & Objects > Virtual IPs**.
2. Select **Create New**.

3. Choose the **VIP Type**.
4. Enter the name of the VIP, for example, `PPTP_Server`.
5. Select the **External Interface** where the packets will be received for the PPTP server.
6. Enter the **External IP Address** for the VIP.
7. Select **Port Forwarding**.
8. Set the **Protocol to TCP**.
9. Enter the **External Service Port** of 1723, the default for PPTP.
10. Enter the **Map to Port** to 1723.
11. Select **OK**.

To define a virtual IP for PPTP passthrough - CLI

```
config firewall vip or config firewall vip6
edit PPTP_Server
    set extintf <interface>
    set extip <ip_address>
    set portforward enable
    set protocol tcp
    set extport 1723
    set mappedport 1723
    set mappedip <destination IP address range>
end
```

You can also use `config firewall vip46` to define a virtual IP from an IPv4 address to an IPv6 address or `config firewall vip64` to define a virtual IP from an IPv6 address to an IPv4 address.

Configuring a port-forwarding security policy

To create a port-forwarding security policy for PPTP passthrough you must first create an address range reserved for the PPTP clients.

To create an address range - GUI

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Select a **Category**.
3. Enter a **Name** for the range, for example, `External_PPTP`.
4. Select a **Type** of **Subnet/IP Range**.
5. Enter the IP address range.
6. Select the **Interface** to the Internet.
7. Select **OK**.

To create an address range - CLI

```
config firewall address OR config firewall address6
edit External_PPTP
    set type ip_range
    set start-ip <ip_address>
    set end-ip <ip_address>
    set associated-interface <internet_interface>
end
```

With the address set, you can add the security policy.

To add the security policy - GUI

1. Go to **Policy & Objects > IPv4** or **Policy & Objects > IPv6** and select **Create New**.
2. Complete the following and select **OK**:

Incoming Interface	The FortiGate interface connected to the Internet.
Source Address	Select the address range created in the previous step.
Outgoing Interface	The FortiGate interface connected to the PPTP server.
Destination Address	Select the VIP address created in the previous steps.
Schedule	always
Service	PPTP
Action	ACCEPT

To add the security policy - CLI

```
config firewall policy or config firewall policy6
  edit <policy_number>
    set srcintf <interface to internet>
    set dstintf <interface to PPTP server>
    set srcaddr <address_range>
    set dstaddr <PPTP_server_address>
    set action accept
    set schedule always
    set service PPTP
  end
```

Testing PPTP VPN connections

To confirm that a PPTP VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The PPTP VPN tunnel initializes when the dialup client attempts to connect.

Logging VPN events

PPTP VPN, activity is logged when enabling VPN logging. The FortiGate unit connection events and tunnel status (up/down) are logged.

To log VPN events

1. Go to **Log & Report > Log Settings**.
2. Enable **Event Logging**.
3. Select **VPN activity event**.
4. Select **Apply**.

To view event logs

1. Go to **Log & Report > VPN Events**.
2. If the option is available to set the log location list, select disk or memory.
3. Select a log event and select **Details**.

Configuring L2TP VPNs

This section describes how to configure a FortiGate unit to establish a Layer Two Tunneling Protocol (L2TP) tunnel with a remote dialup client. The FortiGate implementation of L2TP enables a remote dialup client to establish an L2TP tunnel with the FortiGate unit directly.

According to RFC 2661, an Access Concentrator (LAC) can establish an L2TP tunnel with an L2TP Network Server (LNS). In a typical scenario, the LAC is managed by an ISP and located on the ISP premises; the LNS is the gateway to a private network. When a remote dialup client connects to the Internet through the ISP, the ISP uses a local database to establish the identity of the caller and determine whether the caller needs access to an LNS through an L2TP tunnel. If the services registered to the caller indicate that an L2TP connection to the LNS is required, the ISP LAC attempts to establish an L2TP tunnel with the LNS.

A FortiGate unit can be configured to act as an LNS. The FortiGate implementation of L2TP enables a remote dialup client to establish an L2TP tunnel with the FortiGate unit directly, bypassing any LAC managed by an ISP. The ISP must configure its network access server to forward L2TP traffic from the remote client to the FortiGate unit directly whenever the remote client requires an L2TP connection to the FortiGate unit.

When the FortiGate unit acts as an LNS, an L2TP session and tunnel is created as soon as the remote client connects to the FortiGate unit. The FortiGate unit assigns an IP address to the client from a reserved range of IP addresses. The remote client uses the assigned IP address as its source address for the duration of the connection.

More than one L2TP session can be supported on the same tunnel. FortiGate units can be configured to authenticate remote clients using a plain text user name and password, or authentication can be forwarded to an external RADIUS or LDAP server. L2TP clients are authenticated as members of a user group.

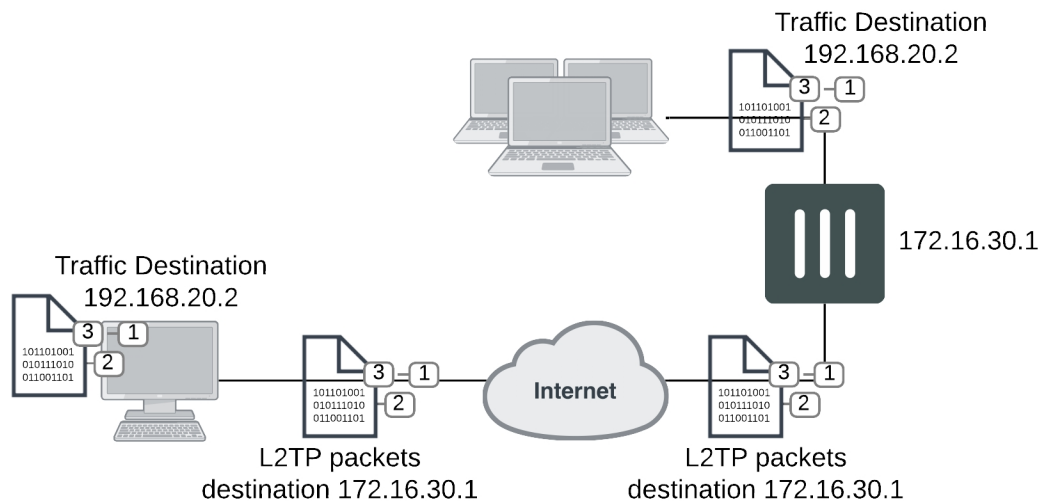

For site-to-site connections, Windows servers use IPsec encryption when you configure the VPN to connect to an L2TP server.

Traffic from the remote client must be encrypted using IPsec before it is encapsulated and routed to the FortiGate unit. Packets originating at the remote client are addressed to a computer on the private network behind the FortiGate unit. Encapsulated packets are addressed to the public interface of the FortiGate unit. See the figure below.

When the FortiGate unit receives an L2TP packet, the unit disassembles the packet and forwards the packet to the correct computer on the internal network. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely.

L2TP encapsulation

FortiGate units cannot deliver non-IP traffic such as Frame Relay or ATM frames encapsulated in L2TP packets — FortiGate units support the IPv4 and IPv6 addressing schemes only

Network topology

The remote client connects to an ISP that determines whether the client requires an L2TP connection to the FortiGate unit. If an L2TP connection is required, the connection request is forwarded to the FortiGate unit directly.

Example L2TP configuration

L2TP infrastructure requirements

- The FortiGate unit must be operating in NAT mode and have a static public IP address.
- The ISP must configure its network access server to forward L2TP traffic from remote clients to the FortiGate unit directly.
- The remote client must not generate non-IP traffic (Frame Relay or ATM frames).

L2TP configuration overview

To configure a FortiGate unit to act as an LNS, you perform the following tasks:

- Create an L2TP user group containing one user for each remote client.
- Enable L2TP on the FortiGate unit and specify the range of addresses that can be assigned to remote clients when they connect.
- Define firewall source and destination addresses to indicate where packets transported through the L2TP tunnel will originate and be delivered.
- Create the security policy and define the scope of permitted services between the source and destination addresses.
- Configure the remote clients.

Authenticating L2TP clients

L2TP clients must be authenticated before a tunnel is established. The authentication process relies on FortiGate user group definitions, which can optionally use established authentication mechanisms such as RADIUS or LDAP to authenticate L2TP clients. All L2TP clients are challenged when a connection attempt is made.

To enable authentication, you must create user accounts and a user group to identify the L2TP clients that need access to the network behind the FortiGate unit.

You can choose to use a plain text password for authentication or forward authentication requests to an external RADIUS or LDAP server. If password protection will be provided through a RADIUS or LDAP server, you must configure the FortiGate unit to forward authentication requests to the authentication server.

Enabling L2TP and specifying an address range

The L2TP address range specifies the range of addresses reserved for remote clients. When a remote client connects to the FortiGate unit, the client is assigned an IP address from this range. Afterward, the FortiGate unit uses the assigned address to communicate with the remote client.

The address range that you reserve can be associated with private or routable IP addresses. If you specify a private address range that matches a network behind the FortiGate unit, the assigned address will make the remote client appear to be part of the internal network.

To enable L2TP and specify the L2TP address range, use the `config vpn l2tp` CLI command.

The following example shows how to enable L2TP and set the L2TP address range using a starting address of 192.168.10.80 and an ending address of 192.168.10.100 for an existing group of L2TP users named L2TP_users:

```
config vpn l2tp
  set sip 192.168.10.80
  set eip 192.168.10.100
  set status enable
  set usrgroup L2TP_users
end
```

Defining firewall source and destination addresses

Before you define the security policy, you must define the source and destination addresses of packets that are to be transported through the L2TP tunnel:

- For the source address, enter the range of addresses that you reserved for remote L2TP clients (for example 192.168.10.[80-100]).
- For the destination address, enter the IP addresses of the computers that the L2TP clients need to access on the private network behind the FortiGate unit (for example, 172.16.5.0/24 for a subnet, or 172.16.5.1 for a server or host, or 192.168.10.[10-15] for an IP address range).

To define the firewall source address

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. Select **Address**.
3. In the **Name** field, type a name that represents the range of addresses that you reserved for remote clients (for example, Ext_L2TPrange).
4. In **Type**, select **IP Range**.
5. In the **Subnet / IP Range** field, type the corresponding IP address range.
6. In **Interface**, select the FortiGate interface that connects to the clients.
7. This is usually the interface that connects to the Internet.
8. Select **OK**.

To define the firewall destination address

1. Go to **Policy & Objects > Addresses** and select **Create New**.
2. In the **Address Name** field, type a name that represents a range of IP addresses on the network behind the FortiGate unit (for example, `Int_L2TPaccess`).
3. In **Type**, select **IP Range**.
4. In the **IP Range** field, type the corresponding IP address range.
5. In **Interface**, select the FortiGate interface that connects to the network behind the FortiGate unit.
6. Select **OK**.

Adding the security policy

The security policy specifies the source and destination addresses that can generate traffic inside the L2TP tunnel and defines the scope of services permitted through the tunnel. If a selection of services are required, define a service group.

To define the traffic and services permitted inside the L2TP tunnel

1. Go to **Policy & Objects > IPv4** or **Policy & Objects > IPv6** and select **Create New**.
2. Enter these settings:

Name	Input a name for the policy.
Incoming Interface	Select the FortiGate interface to the Internet.
Outgoing Interface	Select the FortiGate interface to the internal (private) network.
Source Address	Select the name that corresponds to the address range that reserved for L2TP clients (for example, <code>Ext_L2TPrange</code>).
Destination Address	Select the name that corresponds to the IP addresses behind the FortiGate unit (for example, <code>Int_L2TPaccess</code>).
Schedule	Select ALWAYS, or if a select schedule is required instead, select a schedule that you defined previously.
Service	Select ALL, or if selected services are required instead, select the service group that you defined previously.
Action	ACCEPT

3. Select **OK**.

Configuring a Linux client

This procedure outlines how to install L2TP client software and run an L2TP tunnel on a Linux computer. Obtain an L2TP client package that meets your requirements (for example, `rp-l2tp`). If needed to encrypt traffic, obtain L2TP client software that supports encryption using IPsec.

To establish an L2TP tunnel with a FortiGate unit that has been set up to accept L2TP connections, you can obtain and install the client software following these guidelines:

1. If encryption is required, you will need to verify the IPsec configuration.
2. Download and install the L2TP client package.

3. Configure an L2TP connection to run the L2TP program.
4. Configure routes to determine whether all or some of your network traffic will be sent through the tunnel. You must define a route to the remote network over the L2TP link and a host route to the FortiGate unit.
5. Run `l2tpd` to start the tunnel.

Follow the software supplier's documentation to complete the steps.

To configure the system, you need to know the public IP address of the FortiGate unit, and the user name and password that has been set up on the FortiGate unit to authenticate L2TP clients. Contact the FortiGate administrator if required to obtain this information.

Monitoring L2TP sessions

You can display a list of all active sessions and view activity by port number. By default, port 1701 is used for L2TP VPN-related communications. If required, active sessions can be stopped from this view. Use **FortiView > All Sessions**.

Testing L2TP VPN connections

To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

Logging L2TP VPN events

You can configure the FortiGate unit to log VPN events. For L2TP VPNs, connection events and tunnel status (up/down) are logged.

To log VPN events - GUI

1. Go to **Log & Report > Log Settings**.
2. Enable the storage of log messages to one or more locations.
3. Select **Enable**, and then select **VPN activity event**.
4. Select **Apply**.

To log VPN events - CLI

```
config log memory setting
    set diskfull overwrite
    set status enable
end
config log eventfilter
    set vpn enable
end
```

Session helpers

The FortiOS firewall can analyze most TCP/IP protocol traffic by comparing packet header information to security policies. This comparison determines whether to accept or deny the packet and the session that the packet belongs to.

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. But the packets that carry the actual conversation can use a variety of UDP protocols with a variety of source and destination port numbers. The information about the protocols and port numbers used for a SIP call is contained in the body of the SIP TCP control packets. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and make adjustments to allow those protocols to send packets through the firewall.

This section includes the topics:

- [Viewing the session helper configuration](#)
- [Changing the session helper configuration](#)
- [DCE-RPC session helper \(dcerpc\)](#)
- [DNS session helpers \(dns-tcp and dns-udp\)](#)
- [File transfer protocol \(FTP\) session helper \(ftp\)](#)
- [H.323 and RAS session helpers \(h323 and ras\)](#)
- [H.245 session helper \(h245\)](#)
- [Media Gateway Controller Protocol \(MGCP\) session helper \(mgcp\)](#)
- [ONC-RPC portmapper session helper \(pmap\)](#)
- [PPTP session helper for PPTP traffic \(pptp\)](#)
- [Remote shell session helper \(rsh\)](#)
- [Real-Time Streaming Protocol \(RTSP\) session helper \(rtsp\)](#)
- [Session Initiation Protocol \(SIP\) session helper \(sip\)](#)
- [Trivial File Transfer Protocol \(TFTP\) session helper \(tftp\)](#)
- [Oracle TNS listener session helper \(tns\)](#)

Viewing the session helper configuration

You can view the session helpers enabled on your FortiGate unit in the CLI using the commands below. The following output shows the first two session helpers. The number of session helpers can vary to around 20.

```
show system session-helper
config system session-helper
edit 1
    set name pptp
    set port 1723
```

```
    set protocol 6
  next
    set name h323
    set port 1720
    set protocol 6
  end
  .
  .
```

The configuration for each session helper includes the name of the session helper and the port and protocol number on which the session helper listens for sessions. Session helpers listed on protocol number 6 (TCP) or 17 (UDP). For a complete list of protocol numbers see [Assigned Internet Protocol Numbers](#).

For example, the output above shows that FortiOS listens for PPTP packets on TCP port 1723 and H.323 packets on port TCP port 1720.

If a session helper listens on more than one port or protocol the more than one entry for the session helper appears in the `config system session-helper` list. For example, the `pmap` session helper appears twice because it listens on TCP port 111 and UDP port 111. The `rsh` session helper appears twice because it listens on TCP ports 514 and 512.

Changing the session helper configuration

Normally you will not need to change the configuration of the session helpers. However in some cases you may need to change the protocol or port the session helper listens on.

Changing the protocol or port that a session helper listens on

Most session helpers are configured to listen for their sessions on the port and protocol that they typically use. If your FortiGate unit receives sessions that should be handled by a session helper on a non-standard port or protocol you can use the following procedure to change the port and protocol used by a session helper. The following example shows how to change the port that the `pmap` session helper listens on for Sun RPC portmapper TCP sessions. By default `pmap` listens on TCP port 111.

To change the port that the `pmap` session helper listens on to TCP port 112

1. Confirm that the TCP `pmap` session helper entry is 11 in the session-helper list:

```
show system session-helper 11
config system session-helper
  edit 11
    set name pmap
    set port 111
    set protocol 6
  next
end
```

2. Enter the following command to change the TCP port to 112.

```
config system session-helper
  edit 11
    set port 112
  end
```

3. The `pmap` session helper also listens on UDP port 111. Confirm that the UDP `pmap` session helper entry is 12 in the session-helper list:

```
show system session-helper 12
config system session-helper
edit 12
    set name pmap
    set port 111
    set protocol 17
next
end
```

4. Enter the following command to change the UDP port to 112.

```
config system session-helper
edit 12
    set port 112
end
```

Use the following command to set the h323 session helper to listen for ports on the UDP protocol.

To change the protocol that the h323 session helper listens on

1. Confirm that the h323 session helper entry is 2 in the session-helper list:

```
show system session-helper 2
config system session-helper
edit 2
    set name h323
    set port 1720
    set protocol 6
next
end
```

2. Enter the following command to change the protocol to UDP.

```
config system session-helper
edit 2
    set protocol 17
end
```

If a session helper listens on more than one port or protocol, then multiple entries for the session helper must be added to the session helper list, one for each port and protocol combination. For example, the rtsp session helper listens on TCP ports 554, 7070, and 8554 so there are three rtsp entries in the session-helper list. If your FortiGate unit receives rtsp packets on a different TCP port (for example, 6677) you can use the following command to configure the rtsp session helper to listen on TCP port 6677.

To configure a session helper to listen on a new port and protocol

```
config system session-helper
edit 0
    set name rtsp
    set port 6677
    set protocol 6
end
```

Disabling a session helper

In some cases you may need to disable a session helper. Disabling a session helper just means removing it from the session-helper list so that the session helper is not listening on a port. You can completely disable a session

helper by deleting all of its entries from the session helper list. If there are multiple entries for a session helper on the list you can delete one of the entries to prevent the session helper from listening on that port.

To disable the mgcp session helper from listening on UDP port 2427

1. Enter the following command to find the mgcp session helper entry that listens on UDP port 2427:

```
show system session-helper
.
.
.
edit 19
  set name mgcp
  set port 2427
  set protocol 17
next
.
.
.
```

2. Enter the following command to delete session-helper list entry number 19 to disable the mgcp session helper from listening on UDP port 2427:

```
config system session-helper
  delete 19
```

By default the mgcp session helper listens on UDP ports 2427 and 2727. The previous procedure shows how to disable the mgcp protocol from listening on port 2427. The following procedure completely disables the mgcp session helper by also disabling it from listening on UDP port 2727.

To completely disable the mgcp session helper

1. Enter the following command to find the mgcp session helper entry that listens on UDP port 2727:

```
show system session-helper
.
.
.
edit 20
  set name mgcp
  set port 2727
  set protocol 17
next
.
.
.
```

2. Enter the following command to delete session-helper list entry number 20 to disable the mgcp session helper from listening on UDP port 2727:

```
config system session-helper
  delete 20
```

DCE-RPC session helper (dcerpc)

Distributed Computing Environment Remote Procedure Call (DCE-RPC) provides a way for a program running on one host to call procedures in a program running on another host. DCE-RPC (also called MS RPC for Microsoft RPC) is similar to ONC-RPC. Because of the large number of RPC services, for example, MAPI, the transport

address of an RPC service is dynamically negotiated based on the service program's universal unique identifier (UUID). The Endpoint Mapper (EPM) binding protocol in FortiOS maps the specific UUID to a transport address.

To accept DCE-RPC sessions you must add a security policy with service set to any or to the DEC-RPC pre-defined service (which listens on TCP and UDP ports 135). The dcerpc session helper also listens on TCP and UDP ports 135.

The session allows FortiOS to handle DCE-RPC dynamic transport address negotiation and to ensure UUID-based security policy enforcement. You can define a security policy to permit all RPC requests or to permit by specific UUID number.

In addition, because a TCP segment in a DCE-RPC stream might be fragmented, it might not include an intact RPC PDU. This fragmentation occurs in the RPC layer; so FortiOS does not support parsing fragmented packets.

The DCE-RPC session helper does not support destination NAT (DNAT) or Firewall VIPs unless you are using the OXID Resolver service (also called IOXIDResolver).

DNS session helpers (dns-tcp and dns-udp)

FortiOS includes two DNS session helpers, dns-tcp, a session helper for DNS over TCP, and dns-udp, a session helper for DNS over UDP.

To accept DNS sessions you must add a security policy with service set to any or to the DNS pre-defined service (which listens on TCP and UDP ports 53). The dns-udp session helper also listens on UDP port 53. By default the dns-tcp session helper is disabled. If needed you can use the following command to enable the dns-tcp session helper to listen for DNS sessions on TCP port 53:

```
config system session-helper
  edit 0
    set name dns-tcp
    set port 53
    set protocol 6
  end
```

File transfer protocol (FTP) session helper (ftp)

The FTP session helper monitors PORT, PASV and 227 commands and NATs the IP addresses and port numbers in the body of the FTP packets and opens ports on the FortiGate unit as required.

To accept FTP sessions you must add a security policy with service set to any or to the FTP, FTP_Put, and FTP_GET pre-defined services (which all listen on TCP port 21).

H.323 and RAS session helpers (h323 and ras)

The H.323 session helper supports secure H.323 voice over IP (VoIP) sessions between terminal endpoints such as IP phones and multimedia devices. In H.323 VoIP networks, gatekeeper devices manage call registration, admission, and call status for VoIP calls. The FortiOS h323 session helper supports gatekeepers installed on two different networks or on the same network.

To accept H.323 sessions, you must add a security policy with service set to any or to the H323 pre-defined service (which listens on TCP port numbers 1720 and 1503 and on UDP port number 1719). The h323 session helper listens on TCP port 1720.

The ras session helper is used with the h323 session helper for H.323 Registration, Admission, and Status (RAS) services. The ras session helper listens on UDP port 1719.

Alternate H.323 gatekeepers

The h323 session helper supports using H.323 alternate gatekeepers. All the H.323 endpoints must register with a gatekeeper through the Registration, Admission, and Status (RAS) protocol before they make calls. During the registration process, the primary gatekeeper sends Gatekeeper Confirm (GCF) and Registration Confirm (RCF) messages to the H.323 endpoints that contain the list of available alternate gatekeepers.

The alternate gatekeeper provides redundancy and scalability for the H.323 endpoints. If the primary gatekeeper fails the H.323 endpoints registered with that gatekeeper are automatically registered with the alternate gatekeeper. To use the H.323 alternate gatekeeper, you need to configure security policies that allow H.323 endpoints to reach the alternate gatekeeper.

H.245 session helper (h245)

H.245 is a control channel protocol used for H.323 and other similar communication sessions. H.245 sessions transmit non-telephone signals. H.245 sessions carry information needed for multimedia communication, such as encryption, flow control jitter management and others.

FortiOS includes one H.245 session helper, h245, which serves call in and call out sessions. There is no standard port for H.245. The ports are negotiated through H.323 setup and connect messages. As administrator, you should configure the RAS or H.323 helper if non-standard ports are used for RAS or H323. You do not have to configure the h245 helper because the h323 helper configures the h245 helper.

Media Gateway Controller Protocol (MGCP) session helper (mgcp)

The Media Gateway Control Protocol (MGCP) is a text-based application layer protocol used for VoIP call setup and control. MGCP uses a master-slave call control architecture in which the media gateway controller uses a call agent to maintain call control intelligence, while the media gateways perform the instructions of the call agent.

To accept MGCP sessions you must add a security policy with service set to any or to the MGCP predefined service (which listens on UDP port numbers 2427 and 2727). The h323 session helper also listens on UDP port numbers 2427 and 2727.

The MGCP session helper does the following:

- VoIP signaling payload inspection. The payload of the incoming VoIP signaling packet is inspected and malformed packets are blocked.
- Signaling packet body inspection. The payload of the incoming MGCP signaling packet is inspected according to RFC 3435. Malformed packets are blocked.
- Stateful processing of MGCP sessions. State machines are invoked to process the parsed information. Any out-of-state or out-of-transaction packet is identified and properly handled.
- MGCP Network Address Translation (NAT). Embedded IP addresses and ports in packet bodies is properly translated based on current routing information and network topology, and is replaced with the translated IP address and port number, if necessary.

- Manages pinholes for VoIP traffic. To keep the VoIP network secure, the IP address and port information used for media or signaling is identified by the session helper, and pinholes are dynamically created and closed during call setup.

ONC-RPC portmapper session helper (pmap)

Open Network Computing Remote Procedure Call (ONC-RPC) is a widely deployed remote procedure call system. Also called Sun RPC, ONC-RPC allows a program running on one host to call a program running on another. The transport address of an ONC-RPC service is dynamically negotiated based on the service's program number and version number. Several binding protocols are defined for mapping the RPC program number and version number to a transport address.

To accept ONC-RPC sessions you must add a security policy with service set to any or to the ONC-RPC pre-defined service (which listens on TCP and UDP port number 111). The RPC portmapper session helper (called pmap) handles the dynamic transport address negotiation mechanisms of ONC-RPC.

PPTP session helper for PPTP traffic (pptp)

The PPTP session help supports port address translation (PAT) for PPTP traffic. PPTP provides IP security at the Network Layer. PPTP consists of a control session and a data tunnel. The control session runs over TCP and helps in establishing and disconnecting the data tunnel. The data tunnel handles encapsulated Point-to-Point Protocol (PPP) packets carried over IP.

To accept PPTP sessions that pass through the FortiGate unit you must add a security policy with service set to any or to the PPTP pre-defined service (which listens on IP port 47 and TCP port 1723). The pptp session helper listens on TCP port 1723.

PPTP uses TCP port 1723 for control sessions and Generic Routing Encapsulation (GRE) (IP protocol 47) for tunneling the encapsulated PPP data. The GRE traffic carries no port number, making it difficult to distinguish between two clients with the same public IP address. PPTP uses the source IP address and the Call ID field in the GRE header to identify a tunnel. When multiple clients sharing the same IP address establish tunnels with the same PPTP server, they may get the same Call ID. The call ID value can be translated in both the control message and the data traffic, but only when the client is in a private network and the server is in a public network.

PPTP clients can either directly connect to the Internet or dial into a network access server to reach the Internet. A FortiGate unit that protects PPTP clients can translate the clients' private IP addresses to a pool of public IP addresses using NAT port translation (NAT-PT). Because the GRE traffic carries no port number for address translation, the pptp session helper treats the Call ID field as a port number as a way of distinguishing multiple clients.

After the PPTP establishing a TCP connection with the PPTP server, the client sends a start control connection request message to establish a control connection. The server replies with a start control connection reply message. The client then sends a request to establish a call and sends an outgoing call request message. FortiOS assigns a Call ID (bytes 12-13 of the control message) that is unique to each PPTP tunnel. The server replies with an outgoing call reply message that carries its own Call ID in bytes 12-13 and the client's call ID in bytes 14-15. The pptp session helper parses the control connection messages for the Call ID to identify the call to which a specific PPP packet belongs. The session helper also identifies an outgoing call request message using the control message type field (bytes 8-9) with the value 7. When the session helper receives this message, it parses the control message for the call ID field (bytes 12-13). FortiOS translates the call ID so that it is unique across multiple calls from the same translated client IP. After receiving outgoing call response message, the session helper holds this message and opens a port that accepts GRE traffic that the PPTP server sends. An outgoing call request message contains the following parts:

- The protocol used for the outgoing call request message (usually GRE)
- Source IP address (PPTP server IP)
- Destination IP address (translated client IP)
- Destination port number (translated client call ID)

The session helper identifies an outgoing call reply message using the control message type field (bytes 8-9) with the value 8. The session helper parses these control messages for the call ID field (bytes 12-13) and the client's call ID (bytes 14-15). The session helper then uses the client's call ID value to find the mapping created for the other direction, and then opens a pinhole to accept the GRE traffic that the client sends.

An outgoing call reply message contains the following parts:

- Protocol used for the outgoing call reply message (usually GRE)
- Source IP address (PPTP client IP)
- Destination IP address (PPTP server IP)
- Destination port number (PPTP server Call ID)

Each port that the session opens creates a session for data traffic arriving in that direction. The session helper opens the following two data sessions for each tunnel:

- Traffic from the PPTP client to the server, using the server's call ID as the destination port
- Traffic from the PPTP server to the client, using the client's translated call ID as the destination port

The default timeout value of the control connection is 30 minutes. The session helper closes the pinhole when the data session exceeds the timeout value or is idle for an extended period.

Remote shell session helper (rsh)

Using the remote shell program (RSH), authenticated users can run shell commands on remote hosts. RSH sessions most often use TCP port 514. To accept RSH sessions you must add a security policy with service set to any or to the RSH pre-defined service (which listens on TCP port number 514).

FortiOS automatically invokes the rsh session helper to process all RSH sessions on TCP port 514. The rsh session helper opens ports required for the RSH service to operate through a FortiGate unit running NAT or transparent and supports port translation of RSH traffic.

Real-Time Streaming Protocol (RTSP) session helper (rtsp)

The Real-Time Streaming Protocol (RTSP) is an application layer protocol often used by SIP to control the delivery of multiple synchronized multimedia streams, for example, related audio and video streams. Although RTSP is capable of delivering the data streams itself it is usually used like a network remote control for multimedia servers. The protocol is intended for selecting delivery channels (like UDP, multicast UDP, and TCP) and for selecting a delivery mechanism based on the Real-Time Protocol (RTP). RTSP may also use the SIP Session Description Protocol (SDP) as a means of providing information to clients for aggregate control of a presentation consisting of streams from one or more servers, and non-aggregate control of a presentation consisting of multiple streams from a single server.

To accept RTSP sessions you must add a security policy with service set to any or to the RTSP pre-defined service (which listens on TCP ports 554, 770, and 8554 and on UDP port 554). The rtsp session helper listens on TCP ports 554, 770, and 8554.

The rtsp session help is required because RTSP uses dynamically assigned port numbers that are communicated in the packet body when end points establish a control connection. The session helper keeps track of the port

numbers and opens pinholes as required. In Network Address Translation (NAT) mode, the session helper translates IP addresses and port numbers as necessary.

In a typical RTSP session the client starts the session (for example, when the user selects the Play button on a media player application) and establishes a TCP connection to the RTSP server on port 554. The client then sends an OPTIONS message to find out what audio and video features the server supports. The server responds to the OPTIONS message by specifying the name and version of the server, and a session identifier, for example, 24256-1.

The client then sends the DESCRIBE message with the URL of the actual media file the client wants to play. The server responds to the DESCRIBE message with a description of the media in the form of SDP code. The client then sends the SETUP message, which specifies the transport mechanisms acceptable to the client for streamed media, for example RTP/RTCP or RDT, and the ports on which it receives the media.

In a NAT configuration the rtsp session helper keeps track of these ports and addresses translates them as necessary. The server responds to the SETUP message and selects one of the transport protocols. When both client and server agree on a mechanism for media transport the client sends the PLAY message, and the server begins streaming the media.

Session Initiation Protocol (SIP) session helper (sip)

The sip session helper is described in the VoIP Solutions: SIP Guide.

Trivial File Transfer Protocol (TFTP) session helper (tftp)

To accept TFTP sessions you must add a security policy with service set to any or to the TFTP pre-defined service (which listens on UDP port number 69). The TFTP session helper also listens on UTP port number 69.

TFTP initiates transfers on UDP port 69, but the actual data transfer ports are selected by the server and client during initialization of the connection. The tftp session helper reads the transfer ports selected by the TFTP client and server during negotiation and opens these ports on the firewall so that the TFTP data transfer can be completed. When the transfer is complete the tftp session helper closes the open ports.

Oracle TNS listener session helper (tns)

The Oracle Transparent Network Substrate (TNS) listener listens on port TCP port 1521 for network requests to be passed to a database instance. The Oracle TNS listener session helper (tns) listens for TNS sessions on TCP port 1521. TNS is a foundation technology built into the Oracle Net foundation layer and used by SQLNET.

Advanced concepts

This section provides configuration concepts and techniques to enhance your network security and includes the topics:

- [Single firewall vs. multiple virtual domains](#)
- [Modem](#)
- [FortiExtender](#)
- [Assigning IP address by MAC address](#)
- [IP addresses for self-originated traffic](#)
- [Disk](#)
- [CLI scripts](#)
- [Rejecting PING requests](#)
- [Opening TCP 113](#)
- [Obfuscate HTTP responses](#)

To see a collection of practical articles, go to Fortinet's [Cookbook](#) site and navigate to [Resources > SysAdmin Notes](#).

Single firewall vs. multiple virtual domains

A typical FortiGate setup, with a small to mid-range appliance, enables you to include a number of subnets on your network using the available ports and switch interfaces. This can potentially provide a means of having three or more mini networks for the various groups in a company. Within this infrastructure, multiple network administrators have access to the FortiGate to maintain security policies.

However, the FortiGate unit may not have enough interfaces to match the number of departments in the organization. If the FortiGate unit is running in transparent mode however, there is only one interface, and multiple network branches through the FortiGate are not possible.

A FortiGate unit with Virtual Domains (VDOMs) enabled, provides a means to provide the same functionality in transparent mode as a FortiGate in NAT mode. VDOMs are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs can provide separate security policies and, in NAT mode, completely separate configurations for routing and VPN services for each connected network. For administration, an administrator can be assigned to each VDOM, minimizing the possibility of error or fouling network communications.

By default, most FortiGate units support 10 VDOMs. Many FortiGate models support purchasing a license key to increase the maximum number.

Single firewall vs. vdoms

When VDOMs are not enabled, and the FortiGate unit is in transparent mode, all the interfaces on your unit become broadcast interfaces. The problem is there are no interfaces free for additional network segments.

A FortiGate with three interfaces means only limited network segments are possible without purchasing more FortiGate devices.

With multiple VDOMs you can have one of them configured in transparent mode, and the rest in NAT mode. In this configuration, you have an available transparent mode FortiGate unit you can drop into your network for troubleshooting, and you also have the standard.

This example shows how to enable VDOMs on the FortiGate unit and the basic and create a VDOM accounting on the DMZ2 port and assign an administrator to maintain the VDOM. First enable Virtual Domains on the FortiGate unit.

To enable VDOMs - web-based manager

1. Go to **System > Dashboard > Status**.
2. In the **System Information** widget, select **Enable** for **Virtual Domain**.

Note that on FortiGate-60 series and lower models, you need to enable VDOMs in the CLI only.

The FortiGate unit logs you out. Once you log back in, you will notice that the menu structure has changed. This reflects the global settings for all Virtual Domains.

To enable VDOMs - CLI

```
config system global
    set vdom-admin enable
end
```

Next, add the VDOM called accounting.

To add a VDOM - web-based manager

1. Go to **Global > VDOM > VDOM**, and select **Create New**.
2. Enter the VDOM name `accounting`.
3. Select **OK**.

To add a VDOM - CLI

```
config vdom
  edit <new_vdom_name>
end
```

With the Virtual Domain created, you can assign a physical interface to it, and assign it an IP address.

To assign physical interface to the accounting Virtual Domain - web-based manager

1. Go to **Global > Network > Interface**.
2. Select the DMZ2 port row and select **Edit**.
3. For the **Virtual Domain** drop-down list, select **accounting**.
4. Select the **Addressing Mode** of **Manual**.
5. Enter the IP address for the port of 10.13.101.100/24.
6. Set the **Administrative Access** to **HTTPS** and **SSH**.
7. Select **OK**.

To assign physical interface to the accounting Virtual Domain - CLI

```
config global
  config system interface
    edit dmz2
      set vdom accounting
      set ip 10.13.101.100/24
      set allowaccess https ssh
    next
  end
```

Modem

FortiGate units support the use of wireless, 3G and 4G modems connected using the USB port or, if available, the express card slot. Modem access provides either primary or secondary (redundant) access to the Internet. For FortiGate units that do not include an internal modem (those units with an “M” designation), the modem interface will not appear in the web-based manager until enabled in the CLI. To enable the modem interface enter the CLI commands:

```
config system modem
  set status enable
end
```

You will need to log out of the FortiGate and log back in to see the modem configuration page at **Network > Modem**. Once enabled, modem options become available by going to **Network > Interfaces**.

Note that the modem interface is only available when the FortiGate unit is in NAT mode.

To configure modem settings, go to **> Network > Modem**.

Configuring the modem settings is a matter of entering the ISP phone number, user name and password. Depending on the modem, additional information may need to be supplied such as product identifiers, and initialization strings.

The FortiGate unit includes a number of common modems within its internal database. You can view these by selecting the **Configure Modem** link on the **Modem Settings** page. If your modem is not on the list, select **Create New** to add the information. This information is stored on the device, and will remain after a reboot.

Fortinet has an online database of modem models and configuration settings through FortiGuard. A subscription to the FortiGuard services is not required to access the information. As models are added, you can select the **Configure Modem** link and select **Update Now** to download new configurations.

USB modem port

Each USB modem has a specific dial-out port. This will be indicated with the documentation for your modem. To enable the correct USB port, use the CLI commands:

```
config system modem
    set wireless-port {0 | 1 | 2}
end
```

To test the port, use the diagnose command:

```
diagnose sys modem com /1
```

The 1 will be the value of your USB port selected. The response will be:

```
Serial port: /dev/l
Press Ctrl+W to exit.
```

If the port does not respond the output will be:

```
Can not open modem device '/dev/l' : Broken pipe
```

Modes

The FortiGate unit allows for two modes of operation for the modem; stand alone and redundant. In stand alone mode, the modem connects to a dialup ISP account to provide the connection to the Internet. In redundant mode, the modem acts as a backup method of connecting to the Internet, should the primary port for this function fails.

Configuring either stand alone or redundant modes are very similar. The primary difference is the selection of the interface that the modem will replace in the event of it failing, and the configuration of a PING server to monitor the chosen interface.

Configuring stand alone mode

Configuring stand alone mode is a matter of configuring the modem information and the dialing mode. The dial mode is either **Always Connect** or **Dial on demand**. Selecting **Always Connect** ensures that once the modem has connected, it remains connected to the ISP. Selecting **Dial on Demand**, the modem only calls the ISP if packets are routed to the modem interface. Once sent, the modem will disconnect after a specified amount of time.

To configure standalone mode as needed - GUI

1. Go to **Network > Modem**.
2. Select the **Mode** of **Standalone**.
3. Select the **Dial Mode** of **Dial on Demand**.
4. Select the number of redials the modem attempts if connection fails to 5.
5. Select **Apply**.

To configure standalone mode as needed- CLI

```
config system modem
    set status enable
    set mode standalone
    set auto-dial enable
    set redial 5
end
```

Configuring redundant mode

Redundant mode provides a backup to an interface, typically to the Internet. If that interface fails or disconnects, the modem automatically dials the configured phone number(s). Once connected, the FortiGate unit routes all traffic to the modem interface until the monitored interface is up again. The FortiGate unit pings the connection to determine when it is back online.

For the FortiGate to verify when the interface is back up, you need to configure a Ping server for that interface. You will also need to configure security policies between the modem interface and the other interfaces of the FortiGate unit to ensure traffic flow.

To configure redundant mode as needed - GUI

1. Go to **Network > Modem**.
2. Select the **Mode** of **Redundant**.
3. Select the interface the modem takes over from if it fails.
4. Select the **Dial Mode** of **Dial on Demand**.
5. Select the number of redials the modem attempts if connection fails to 5.
6. Select **Apply**.

To configure standalone mode as needed- CLI

```
config system modem
    set status enable
    set mode redundant
    set interface wan1
    set auto-dial enable
    set redial 5
end
```

Link Health Monitor

Adding a link health monitor is required for routing fail over traffic. A link health monitor will confirm the connectivity of the device's interface

To add a link health monitor

```
config system link-monitor
  edit "Example1"
    set srcint <Interface_sending_probe>
    set server <ISP_IP_address>
    set protocol <Ping or http>
    set gateway-ip <the_gateway_IP_to_reach_the_server_if_required>
    set failtime <failure_count>
    set interval <seconds>
    set update-cascade-interface enable
    set update-static-route enable
    set status enable
  end
```

Additional modem configuration

The CLI provides additional configuration options when setting up the modem options including adding multiple ISP dialing and initialization options and routing. For more information, see the CLI Reference.

Modem interface routing

The modem interface can be used in FortiOS as a dedicated interface. Once enabled and configured, you can use it in security policies and define static and dynamic routing. Within the CLI commands for the modem, you can configure the distance and priority of routes involving the modem interface. The CLI commands are:

```
config system modem
  set distance <route_distance>
  set priority <priority_value>
end
```

For more information on the routing configuration in the CLI, see the CLI Reference. For more information on routing and configuring routing, see the Advanced Routing Guide.

Assigning IP address by MAC address

To prevent users from changing their IP addresses and causing IP address conflicts or unauthorized use of IP addresses, you can bind an IP address to a specific MAC address using DHCP.

Use the CLI to reserve an IP address for a particular client identified by its device MAC address and type of connection. The DHCP server then always assigns the reserved IP address to the client. The number of reserved addresses that you can define ranges from 10 to 200 depending on the FortiGate model.

After setting up a DHCP server on an interface by going to **Network > Interfaces**, select the blue arrow next to **Advanced** to expand the options. If you know the MAC address of the system select **Create New** to add it, or if the system has already connected, locate it in the list, select the check box and select **Add from DHCP Client List**.

You can also match an address to a MAC address in the CLI. In the example below, the IP address 10.10.10.55 for User1 is assigned to MAC address 00:09:0F:30:CA:4F.

```
config system dhcp reserved-address
  edit User1
    set ip 10.10.10.55
    set mac 00:09:0F:30:CA:4F
    set type regular
  end
```

IP addresses for self-originated traffic

On the FortiGate unit, there are a number of protocols and traffic that is specific to the internal workings of FortiOS. For many of these traffic sources, you can identify a specific port/IP address for this self-originating traffic. The following traffic can be configured to a specific port/IP address:

- SNMP
- Syslog
- alert email
- FortiManager connection IP
- FortiGuard services
- FortiAnalyzer logging
- NTP
- DNS
- Authorization requests such as RADIUS
- FSSO

Configuration of these services is performed in the CLI. In each instance, there is a command `set source-ip`. For example, to set the source IP of NTP to be on the DMZ1 port with an IP of 192.168.4.5, the commands are:

```
config system ntp
  set ntpsync enable
  set syncinterval 5
  set source-ip 192.168.4.5
end
```

To see which services are configured with source-ip settings, use the `get` command:

```
get system source-ip status
```

The output will appear similar to the sample below:

```
NTP: x.x.x.x
DNS: x.x.x.x
SNMP: x.x.x.x
Central Management: x.x.x.x
FortiGuard Updates (AV/IPS): x.x.x.x
FortiGuard Queries (WebFilter/SpamFilter): x.x.x.x
```

Disk

To view the status and storage information of the local disk on your FortiGate unit, go to **System > Advanced**. The **DiskSettings** menu appears only on FortiGate units with an internal hard or flash disk.

Formatting the disk

The internal disk of the FortiGate unit (if available) can be formatted by going to **System > Advanced** and selecting **Disk Settings**.

Formatting the disk will erase all data on it, including databases for antivirus and IPS; logs, quarantine files, and WAN optimization caches. The FortiGate unit requires a reboot once the disk has been formatted.

Setting space quotas

If the FortiGate unit has an internal hard or flash disk, you can allocate the space on the disk for specific logging and archiving, and WAN optimization. By default, the space is used on an as required basis. As such, a disk can fill up with basic disk logging, leaving less potential space for quarantine.

By going to **System > Advanced**, you can select the **Edit** icon for **Logging and Archiving** and **WAN Optimization & Web Cache** and define the amount of space each log, archive and WAN optimization has on the disk.

CLI scripts

To upload bulk CLI commands and scripts, go to **System > Advanced**.

Scripts are text files containing CLI command sequences. Scripts can be used to deploy identical configurations to many devices. For example, if all of your devices use identical security policies, you can enter the commands required to create the security policies in a script, and then deploy the script to all the devices which should use those same settings.

Use a text editor such as Notepad or other application that creates simple text files. Enter the commands in sequence, with each line as one command, similar to examples throughout the FortiOS documentation set.

If you are using a FortiGate unit that is not remotely managed by a FortiManager unit or the FortiGuard Analysis and Management Service, the scripts you upload are executed and discarded. If you want to execute a script more than once, you must keep a copy on your management PC.

If your FortiGate unit is configured to use a FortiManager unit, you can upload your scripts to the FortiManager unit, and run them from any FortiGate unit configured to use the FortiManager unit. If you upload a script directly to a FortiGate unit, it is executed and discarded.

If your FortiGate unit is configured to use FortiGuard Analysis and Management Service, scripts you upload are executed and stored. You can run uploaded scripts from any FortiGate unit configured with your FortiGuard Analysis and Management Service account. The uploaded script files appear on the FortiGuard Analysis and Management Service portal web site.

Uploading script files

After you have created a script file, you can then upload it through **System > Advanced**. When a script is uploaded, it is automatically executed.

Commands that require the FortiGate unit to reboot when entered in the command line will also force a reboot if included in a script.

To execute a script

1. Go to **System > Advanced**.
2. Enable **Configuration Scripts**.
3. Select **Upload and Run a New Script** to locate the script file.
4. Select **Apply**.

If the FortiGate unit is not configured for remote management, or if it is configured to use a FortiManager unit, uploaded scripts are discarded after execution. Save script files to your management PC if you want to execute them again later.

If the FortiGate unit is configured to use the FortiGuard Analysis and Management Service, the script file is saved to the remote server for later reuse. You can view the script or run it from the FortiGuard Analysis and Management Service portal web site.

Auto repeat of CLI commands

Occasionally there is a need to repeatedly run a diagnose command over a long period of time (like checking CPU or memory usage, or checking proxy health). Previously, this could only be done with external console connections. With FortiOS 5.4.0, this can be done in a script using the `interval` and `repeat` commands.

Scripts can be uploaded as a file from the CLI or GUI. To upload scripts from the GUI go to **System > Advanced > Configuration Scripts** and upload and run the script.

To configure the schedule and scripts, use the following syntax:

```
config system auto-script
  edit <ScriptName>
    set interval
    set repeat
    set script
  end
end
```

`interval` the interval time in seconds between instances of the script running.

`repeat` the number of times to repeat the running of the script. The value 0 is used to set an infinite number of repetitions.

`start` **select** `manual` to start the script manually or `auto` to start the script automatically

`script` the contents of the script.

This feature may not be available on all models as a hard drive is necessary to make use of it.

CLI option to limit script output size

The CLI command `set output-size` limits the size of an auto script in megabytes and prevents the memory from being used up by the script's output.

CLI Syntax

```
config system auto-script
  edit <script name>
    set output-size <integer>
  next
end
```

Enter an integer value from 10 to 1024. Default is 10.

Execute restore script command

The `execute restore script` command merges arbitrary configlets into the running configuration from a script. You can carry out the command's authentication with either a username and password or with a certificate.

If the configuration in the script fails for any reason, the system will revert back to running configurations without interrupting the network.

To load script from the FTP, SCP, or TFTP servers, enter the following CLI command:

```
execute restore script {ftp | scp |  
tftp} <dir / filename in server> <server ip> <username> <password>
```

To view the results of the last restored script, enter the following CLI command:

```
execute restore script lastlog <dir / filename in server> <server ip> <username>  
<password>
```

Rejecting PING requests

The factory default configuration of your FortiGate unit allows the default external interface to respond to ping requests. Depending on the model of your FortiGate unit the actual name of this interface will vary. For the most secure operation, you should change the configuration of the external interface so that it does not respond to ping requests. Not responding to ping requests makes it more difficult for a potential attacker to detect your FortiGate unit from the Internet. One such potential threat are Denial of Service (DoS) attacks.

A FortiGate unit responds to ping requests if ping administrative access is enabled for that interface.

To disable ping administrative access - web-based manager

1. Go to **System > Network > Interface**.
2. Choose the external interface and select **Edit**.
3. Clear the **Ping Administrative Access** check box.
4. Select **OK**.

In the CLI, when setting the allowaccess settings, by selecting the access types and not including the PING option, that option is then not selected. In this example, only HTTPS is selected.

To disable ping administrative access - CLI

```
config system interface  
edit external  
set allowaccess https  
end
```

Opening TCP 113

Although seemingly contrary to conventional wisdom of closing ports from hackers, this port, which is used for ident requests, should be opened.

Port 113 initially was used as an authentication port, and later defined as an identification port (see RFC 1413). Some servers may still use this port to help in identifying users or other servers and establish a connection. Because port 113 receives a lot of unsolicited traffic, many routers, including on the FortiGate unit, close this port.

The issue arises in that unsolicited requests are stopped by the FortiGate unit, which will send a response saying that the port is closed. In doing so, it also lets the requesting server know there is a device at the given address, and thus announcing its presence. By enabling traffic on port 113, requests will travel to this port, and will most likely, be ignored and never responded to.

By default, the ident port is closed. To open it, use the following CLI commands:

```
config system interface
```

```
edit <port_name>
    set ident_accept enable
end
```

You could also further use port forwarding to send the traffic to a non-existent IP address and thus never have a response packet sent.

Obfuscate HTTP responses from SSL VPN

The FortiGate unit can obfuscate the HTTP responses from SSL VPN servers. By default this option is not enabled. To obfuscate HTTP headers, use the following CLI command:

```
config vpn ssl settings
    set url-obscurate {enable | disable}
end
```

Blocking land attacks in transparent mode

Enabling blocking land attacks allows BFD echo packets to pass through the FortiGate.

Since it's a system settings option you can enable or disable blocking land attacks for individual VDOMs if your FortiGate is operating with multiple VDOMs.

Another reason to enable this feature would be if your FortiGate is blocking BFD echo packets that should be allowed to pass through the FortiGate. For example, a FortiGate operating in transparent mode between two routers with a policy that allows all traffic may block BFD echo communication between the routers if blocking land attacks is disabled.

Use the following command to block land attacks and allow BFD echo packets. This option is disabled by default.

Syntax

```
config system settings
    set block-land-attack enable
end
```

Multi-dimension tagging

Multi-dimension tagging is available for address, device, and interface objects.

Tags can be configured in the GUI under **System > Tags**. Once created, these tags can be assigned to network interfaces, addresses, and custom devices and groups. In addition, a **Tags** column has been added for each of these GUI locations, including under **User & Device > Device Inventory**.

Syntax

The tagging option is available under `config user device` and `device-group`:

```
config user [device | device-group]
edit <name>
    config tagging
        edit <name>
            set category <object-tag-name>
            set tags <name>
        next
    end
```

```

    next
end

```

The same tagging option is also available under `config firewall multicast-address`, `multicast-address6`, `address`, `address6`, `addrgrp`, `addrgrp6`, `proxy-address`, and `config system interface` and `zone` (respectively):

```

config user [multicast-address | multicast-address6 | address | address6 | addrgrp |
  addrgrp6 | proxy-address]
  edit <name>
    config tagging
      edit <name>
        set category <object-tag-name>
        set tags <name>
      next
    end
  next
end

config system [interface | zone]
  edit <name>
    config tagging
      edit <name>
        set category <object-tag-name>
        set tags <name>
      next
    end
  next
end

```

Chapter 25 - Traffic Shaping

The following chapters are included in this document:

[The purpose of traffic shaping](#) describes traffic shaping theories and QoS.

[Traffic shaping methods](#) lists different methods of applying traffic shaping within FortiOS, and explains how to use Type of Service (ToS) and Differentiated Services (DiffServ).

[Examples](#) provides basic application scenarios for traffic shapers.

[Troubleshooting traffic shaping](#) lists diagnose commands that you can use to determine if traffic shapers are working correctly.

What's new in FortiOS 6.0

The following list contains new traffic shaping features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["Interface-based traffic shaping"](#) on page 2805
- ["Internet services support"](#) on page 2809

The purpose of traffic shaping

With the ever-increasing demands on network systems for a number of protocols, including email, HTTP traffic both internally and externally to the Internet, voice over IP, FTP, and more, slow traffic is becoming a reality. Important traffic may even be dropped or slowed to an unusable speed. Web traffic delays can result in a loss of revenue for businesses. Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. There's a physical limitation to the amount of data that can be buffered and to the length of time it can be buffered.

FortiGate devices provide Quality of Service (QoS) by applying bandwidth limits and prioritization. You can use traffic shaping to adjust how a FortiGate allocates resources to different types of traffic to improve performance and stability of latency sensitive or bandwidth intensive network applications.

Traffic shaping, or traffic management, controls the bandwidth available and sets the priority of traffic processed by the policy to control the volume of traffic for a specific period (bandwidth throttling) or rate the traffic is sent (rate limiting).

Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. But there is a physical limitation to the amount of data which can be buffered and to the length of time. Once these thresholds are surpassed, frames and packets are dropped, and sessions are affected in other ways.

A basic traffic shaping approach is to prioritize certain traffic flows over other traffic whose potential loss is less disadvantageous. This means that you accept certain sacrifices in performance and stability on low-priority traffic, to increase or guarantee performance and stability on high-priority traffic.

If, for example, you're applying bandwidth limitations to certain flows, you must accept the fact that these sessions can be limited and therefore negatively impacted.

Note that traffic shaping is effective for normal IP traffic at normal traffic rates. Traffic shaping isn't effective during periods when traffic exceeds the capacity of the FortiGate. Because packets must be received by the FortiGate before they're subject to traffic shaping, if the FortiGate can't process all of the traffic it receives, then dropped packets, delays, and latency are likely to occur.

To ensure that traffic shaping is working at its best, make sure that the interface Ethernet statistics show no errors, collisions, or buffer overruns.

Accelerated interfaces (NPx network processors and CE) affect traffic shaping. For more information, see the FortiOS [What's new in FortiOS 6.0.2](#) guide.

QoS

Quality of Service (QoS) is the capability to adjust some quality aspects of your overall network traffic. This can include such techniques as priority-based queuing and traffic policing. Because bandwidth is finite and because some types of traffic are slow, jitter or packet loss sensitive, bandwidth intensive, or operation critical, QoS can be a useful tool for optimizing the performance of various applications on your network.

Before implementing QoS, you should first identify the types of traffic that are important to your organization, the types of traffic that use high amounts of bandwidth, and the types of traffic that are sensitive to latency or packet loss.

For example, a company might want to guarantee sufficient bandwidth for revenue producing e-commerce traffic. They need to ensure that transactions can be completed and that clients don't experience service delays and

interruptions. At the same time, the company may need to ensure low latency for voice over IP (VoIP) traffic used by sales and customer support, while traffic latency and bursts may be less critical to the success of other network applications such as long term, resumable file transfers. Many organizations discover that QoS is especially important for managing their voice and streaming multimedia traffic. These types of traffic can rapidly consume bandwidth and are sensitive to latency.

Discovering the needs and relative importance of each traffic type on your network helps you to design an appropriate overall approach, including how you to configure each available QoS component technique. Some organizations discover that they only need to configure bandwidth limits for some services. Other organizations determine that they need to fully configure interface and security policy bandwidth limits for all services, and prioritize queuing of critical services relative to traffic rate.

You can implement QoS on FortiGate devices using the following techniques:

Technique	Description
Traffic policing	Drops packets that don't conform to bandwidth limitations
Traffic shaping	Ensures that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee isn't being met. Also ensures that the traffic can't consume bandwidth greater than the maximum at any given instance in time. Flows greater than the maximum rate are subject to traffic policing.
Queuing	Transmits packets in the order of their assigned priority queue for that physical interface. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues is transmitted.

When you're deciding how to configure QoS techniques, it can be helpful to know when FortiGate devices employ each technique in the overall traffic processing flow, and the considerations that arise from those mechanisms.

Traffic policing

A FortiGate begins to process traffic as it arrives (ingress) and departs (egress) on an interface. In later phases of network processing, such as enforcing maximum bandwidth use on sessions handled by a security policy, if the current rate for the destination interface or traffic regulated by that security policy is too high, the FortiGate may drop the packet. Time spent on prior processing, such as web filtering, decryption, or IPS, is often wasted on packets that aren't forwarded. This applies to VLAN interfaces and physical interfaces.

You can prevent this wasted effort on ingress by configuring the FortiGate to preemptively drop excess packets when they're received at the source interface, before most other traffic processing is performed:

```
config system interface
  edit <interface_name>
    set inbandwidth <limit>
  next
end
```

where <limit> is the bandwidth limit for incoming traffic, in kbps. Excess packets are dropped. If inbandwidth is 0, the rate isn't limited.

A similar CLI command is available that can be performed on egress:

```
config system interface
```

```
edit <interface_name>
    set outbandwidth <limit>
next
end
```

As with ingress, setting the rate to 0 (zero) sets the rate to unlimited.

Rate limiting traffic accepted by the interface allows you to restrict incoming traffic to rates that, while no longer the full capacity of the interface, at the traffic shaping point in the processing are more likely to result in acceptable rates of outgoing traffic per destination interface or all security policies. This conserves FortiGate processing resources for those packets that are more likely to be viable completely to the point of egress.

Excessive traffic policing can degrade network performance rather than improve it. For more information about factors that affect traffic policing, see [Important considerations on page 2789](#).

NP6 interfaces on FortiGate devices don't fully support bandwidth limits. When you set the outbandwidth setting on an NP6 interface, the FortiGate implements a lower bandwidth limit than the one that you configure. The inbandwidth setting has no effect on an NP6 interface, unless you disable NP offloading for the traffic on that interface.

Bandwidth guarantee, limit, and priority interactions

After packet acceptance, the FortiGate classifies traffic and may apply traffic policing at additional points during processing. It may also apply QoS techniques, such as prioritization and traffic shaping. Traffic shaping consists of a mixture of traffic policing to enforce bandwidth limits, and priority queue adjustment to assist packets in achieving the guaranteed rate.

If you have configured prioritization, the FortiGate prioritizes egressing packets by distributing them among FIFO (first in, first out) queues associated with each possible priority number. Each physical interface has six priority queues. Virtual interfaces don't have their own queues, and instead use the priority queues of the physical interface to which they are bound.

Each physical interface's six queues are queue 0 to queue 5, where queue 0 is the highest priority queue. However, for reasons described below, you may observe that your traffic uses only a subset of those six queues. Some traffic may always use a certain queue number. Some queuing may vary by the packet rate or mixture of services. Some queue numbers may be used only by through traffic for which you have configured traffic shaping in the security policy that applies to that traffic session. For example:

- Administrative access traffic will always use queue 0.
- Traffic matching security policies without traffic shaping may use queue 0, queue 1, or queue 2. Which queue will be used depends on the priority value you have configured for packets with that Type of Service (ToS) bit value, if you have configured ToS-based priorities.
- Traffic matching security policies with traffic shaping may use any queue. Which queue will be used depends on whether the packet rate is currently below the guaranteed bandwidth (queue 0), or above the guaranteed bandwidth. Packets at rates greater than the maximum bandwidth limit are dropped.
- If the global tos-based-priority is low (3), the priority in a traffic shaper is medium (2) and a packet flows through a policy that refers to the traffic shaper, the packet will be assigned the priority defined by the traffic shaper, in this case medium (2).

Prioritization and traffic shaping behavior varies according to your configuration, the service types and traffic volumes, and whether the traffic is through traffic, or the traffic originates from or terminates at the FortiGate itself.

FortiGate traffic

Security policies don't apply to administrative access to the FortiGate through HTTPS or SSH, or IPsec tunnel negotiations, and therefore FortiGate devices don't apply traffic shaping. Such traffic also uses the highest priority queue, queue 0. In other words, packet priority = 0.

Exceptions to this rule include traffic types that are connections related to a session governed by a security policy. For example, if you enabled scanning by FortiGuard antivirus, traffic from the sender technically terminates at the FortiGate proxy that scans that traffic type. The FortiGate initiates a second connection that transmits scanned content to its destination. Because the second connection's traffic is technically originating from the FortiGate proxy and therefore the FortiGate itself, it uses the highest priority queue, queue 0. However, this connection is logically associated with through traffic, and is therefore subject to possible bandwidth enforcement and guarantees in its governing security policy. In this way, it behaves partly like other through traffic.

Through traffic

For traffic passing through the FortiGate, the method a FortiGate uses to determine the priority queue varies by whether traffic shaping is enabled or not. Packets may or may not use a priority queue directly or indirectly derived from the Type of Service (ToS) bit — sometimes used instead with differentiated services — in the packet's IP header.

If traffic shaping isn't applied to a security policy, the FortiGate doesn't limit or guarantee bandwidth, and traffic for that session uses the priority queue determined directly by matching the ToS bit in its header with the configured values:

```
config system global
  set traffic-priority tos
  set traffic-priority-level {high | low | medium}
end
```

or, if you have configured a priority specifically for that ToS bit value:

```
config system tos-based-priority
  edit <id_int>
    set tos [0-15]
    set priority {high | low | medium}
  end
```

where `tos` is the value of the ToS bit in the packet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in the second location will override the global ToS-based priority. In other words, packet priority = ToS-based priority.

For example, you might specify that packets with a ToS bit value of 2 should use queue 0, which is the highest priority queue:

```
config system tos-based-priority
  edit 15
    set tos 2
    set priority high
  next
end
```

If traffic shaping is applied to a security policy using a shared shaper, the FortiGate may subject packets to traffic policing or priority queue increases in an effort to meet bandwidth guarantees configured in the shaper.

For example, you might create a shared traffic shaper, where `high` has a priority value of 1 and `low` is 3, and `<rate>` is the bandwidth limit in kilobits per second:

```
config firewall shaper traffic-shaper
  edit <shaper_name>
    ...
    set priority {high | medium | low}
    set maximum-bandwidth <rate>
    set guaranteed-bandwidth <rate>
  end
```

Note that it's also necessary to create a traffic shaping policy and set it to use the shared traffic shaper:

```
config firewall shaping-policy
  edit <policy ID>
    ...
    set srcaddr <source address>
    set dstaddr <destination address>
    set service <service name>
    set dstintf <destination interface list>
    set traffic-shaper <shaper_name>
  end
```

The following diagram shows traffic queuing as the packet rate increases.

- If the current packet rate is less than guaranteed bandwidth, packets use priority queue 0: packet priority = 0.
- If the current packet rate is greater than guaranteed bandwidth but less than maximum bandwidth, the FortiGate assigns a priority queue by adding the numerical value of the security policy-based priority, where the value of `High` is 1, and `Low` is 3, with the numerical value of the ToS-based priority, where `high` has a priority value of 0 and `low` is 2. Because the two values are added, depending on the configured ToS-based priorities, packets in this category could use queues from queue 1 to queue 5. In other words: packet priority = ToS-based priority + security policy-based priority.

- If you enabled traffic shaping in the security policy, and the security policy's Traffic Priority is Low (value 3), and the priority normally applied to packets with that ToS bit is `medium` (value 1), then packets have a total packet priority of 4, and use priority queue 4.
- If the current packet rate exceeds the maximum bandwidth, excess packets are dropped.

Calculation and regulation of packet rates

Packet rates specified for Maximum Bandwidth or Guaranteed Bandwidth are:

$$\text{rate} = \text{amount} / \text{time}$$

where rate is expressed in Kbps

Burst size at any given instant can't exceed the amount configured for maximum bandwidth. Packets that exceed this are dropped. Packets deduct from the amount of bandwidth available to subsequent packets and available bandwidth regenerates at a fixed rate. As a result, bandwidth available to a given packet may be less than the configured rate, down to a minimum of 0 Kbps.

Rate calculation and behavior can alternatively be described using the token bucket metaphor, where:

- A traffic flow has an associated bucket, which represents burst size bounds, and is the size of your configured bandwidth limit.
- The bucket receives tokens, which represent available bandwidth, at the fixed configured rate.
- As time passes, tokens are added to the bucket, up to the capacity of the bucket. Excess tokens are discarded.
- When a packet arrives, the packet must deduct bandwidth tokens from the bucket equal to its packet size in order to egress.
- Packets can't egress if there are insufficient tokens to pay for its egress. These nonconforming packets are dropped.

Bursts aren't redistributed over a longer interval, so bursts are propagated rather than smoothed, although their peak size is limited.

Maximum burst size is the capacity of the bucket (the configured bandwidth limit). Actual size varies by the current number of tokens in the bucket, which may be less than bucket capacity, due to deductions from previous packets and the fixed rate at which tokens accumulate. A depleted bucket refills at the rate of your configured bandwidth limit. Bursts can't borrow tokens from other time intervals. This behavior is illustrated in the graph below.

Bursts and bandwidth limits over time

By limiting traffic peaks and token regeneration in this way, the available bandwidth at any given moment may be less than bucket capacity, but your limit on the total amount per time interval is ensured. Total bandwidth use during each interval of one second is, at most, the integral of your configured rate.

You may observe that external clients, such as FTP or BitTorrent clients, initially report rates between Maximum Bandwidth and twice that of Maximum Bandwidth, depending on the size of their initial burst. This is notably so when a connection is initiated following a period of no network activity. The apparent discrepancy in rates is caused by a difference in perspective when delimiting time intervals. A burst from the client may initially consume all tokens in the bucket, and before the end of one second, as the bucket regenerates, be allowed to consume almost another bucket's worth of bandwidth. From the perspective of the client, this constitutes one time interval. From the perspective of the FortiGate, however, the bucket can't accumulate tokens while full. Therefore, the time interval for token regeneration begins after the initial burst, and doesn't contain the burst. These different points of reference result in an initial discrepancy equal to the size of the burst — the client's rate contains it, but the FortiGate device's rate doesn't. If the connection is sustained to its limit and time progresses over an increasing number of intervals, however, this discrepancy decreases in importance relative to the bandwidth total, and the client's reported rate will eventually approach that of the configured rate limit for the FortiGate device.

For example, the Maximum Bandwidth might be 50 Kbps and there has been no network activity for one or more seconds. The bucket is full. A burst from an FTP client immediately consumes 50 kilobits. Because the bucket completely regenerates over one second, by the time almost another second has elapsed from the initial burst, traffic can consume another 49.999 kilobits, for a total of 99.999 kilobits between the two points in time. From the vantage point of an external FTP client regulated by this bandwidth limit, it therefore initially appears that the bandwidth limit is 99.999 Kbps, almost twice the configured limit of 50 Kbps. However, bucket capacity only regenerates at your configured rate of 50 Kbps, and so the connection can only consume a maximum of 50 kilobits during each second thereafter. The result is that as bandwidth consumption is averaged over an increasing number of time intervals, each of which are limited to 50 Kbps, the effects of the first interval's doubled

bandwidth size diminishes proportionately, and the client's reported rate eventually approaches your configured rate limit. The following table shows the effects of a 50 Kbps limit on client reported rates.

Total size transferred (kilobits)	Time (seconds)	Rate reported by client (Kbps)
99.999 (50 + 49.999)	1	99.999
149.999	2	74.999
199.999	3	66.666
249.999	4	62.499
299.999	5	59.998
349.999	6	58.333
...

Guaranteed Bandwidth can also be described using a token bucket metaphor. However, because this feature attempts to achieve or exceed a rate rather than limit it, the FortiGate doesn't discard non-conforming packets, as it does for Maximum Bandwidth. Instead, when the flow doesn't achieve the rate, the FortiGate increases the packets' priority queue, in an effort to increase the rate.

Guaranteed and maximum bandwidth rates apply to the bidirectional total for all sessions controlled by the security policy. For example, an FTP connection may entail two separate connections for the data and control portion of the session. Some packets may be reply traffic rather than initiating traffic. All packets for both connections are counted when calculating the packet rate for comparison with the guaranteed and maximum bandwidth rate.

Important considerations

By implementing Quality of Service (QoS), you trade some performance and/or stability from traffic X by discarding packets or introducing latency in order to improve performance and stability of traffic Y. The best traffic shaping configuration for your network balances the needs of each traffic flow by considering not only the needs of your particular organization, but also the resiliency and other characteristics of each particular service.

For example, you may find that web browsing traffic is both more resistant to interruptions or latency and less business critical than UDP or VoIP traffic, and so you might implement less restrictive QoS measures on UDP or VoIP traffic than on HTTP traffic.

An appropriate QoS configuration also takes into account the physical limits of your network devices and the interactions of the QoS mechanisms described in ["Bandwidth guarantee, limit, and priority interactions" on page 2784](#).

You may choose to configure QoS differently based on the hardware limits of your network and FortiGate. Traffic shaping may be less beneficial in extremely high-volume situations where traffic exceeds a network interface's or your FortiGate model's overall physical capacity. A FortiGate must have enough resources, such as memory and processing power, to process all traffic it receives, and to process it at the required rate. If it doesn't have this capacity, then dropped packets and increased latency are likely to occur. For example, if the total amount of memory available for queuing on a physical interface is frequently exceeded by your network's typical packet

rates, frames and packets must be dropped. In such a situation, you might choose to implement QoS using a higher model FortiGate, or to configure an incoming bandwidth limit on each interface.

Incorrect traffic shaping configurations can actually further degrade certain network flows, because excessive discarding of packets or increased latency beyond points that can be gracefully handled by that protocol can create additional overhead at upper layers of the network, which may be attempting to recover from these errors. For example, a configuration might be too restrictive on the bandwidth accepted by an interface, and may therefore drop too many packets, resulting in the inability to complete or maintain a SIP call.

To optimize traffic shaping performance, first ensure that the Ethernet statistics for the network interface are clean of errors, collisions, or buffer overruns. To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

If these aren't clean, adjust the FortiGate and settings of routers or other network devices that are connected to the FortiGate. For more information, see ["Troubleshooting traffic shaping" on page 2829](#).

Once Ethernet statistics are clean, you may want to use only some of the available FortiGate QoS techniques, or configure them differently, based on the nature of FortiGate QoS mechanisms described in ["Bandwidth guarantee, limit, and priority interactions" on page 2784](#).

Configuration considerations include:

- For maximum bandwidth limits, ensuring that bandwidth limits at the source interface and security policy aren't too low, which can cause the FortiGate to discard an excessive number of packets.
- For prioritization, considering the ratios of how packets are distributed between available queues, and which queue is used by which types of services. If you assign most packets to the same priority queue, it negates the effects of configuring prioritization. If you assign many high bandwidth services to high priority queues, lower priority queues may be starved for bandwidth and experience increased or indefinite latency. For example, you may want to prioritize a latency-sensitive service, such as SIP, over a bandwidth-intensive service such as FTP. Consider also that bandwidth guarantees can affect the queue distribution, assigning packets to queue 0 instead of their typical queue in high-volume situations.
- You may or may not want to guarantee bandwidth, because it causes the FortiGate to assign packets to queue 0 if the guaranteed packet rate isn't currently being met. Comparing queuing behavior for lower-bandwidth and higher-bandwidth situations, this would mean that effects of prioritization only become visible as traffic volumes rise and exceed their guarantees. Because of this, you might want only some services to use bandwidth guarantees, to avoid the possibility that in high-volume situations all traffic uses the same queue, thereby negating the effects of configuring prioritization.
- For prioritization, configure prioritization for all through traffic. You may want to configure prioritization by either ToS-based priority or security policy priority, but not both. This simplifies analysis and troubleshooting.

Traffic subject to both security policy and ToS-based priorities use a combined priority from both of those parts of the configuration, while traffic subject to only one of the prioritization methods will use only that priority. If you configure both methods, or if you configure either method for only a subset of your traffic, packets for which a combined priority applies will frequently receive a lower priority queue than packets for which you have only configured one priority method, or for which you have not configured prioritization.

For example, if both ToS-based priority and security policy priority both dictate that a packet should receive a medium priority, in the absence of bandwidth guarantees, a packet uses queue 3, while if only ToS-based priority is configured, the packet uses queue 1, and if only security policy-based priority is configured, the packet uses queue 2. If no prioritization is configured, the packet uses queue 0.

For example alternative QoS implementations that illustrate these considerations, see ["Examples" on page 2818](#).

Traffic shaping methods

There are three types of traffic shaping configurations in FortiOS. Each type has a specific function, and all types can be used together in varying configurations. Policy shaping allows you to define the maximum bandwidth and the guaranteed bandwidth set for a security policy. Per-IP traffic shaping allows you to define traffic control on a more granular level. Application traffic shaping goes further, allowing traffic controls on specific applications or application groupings.

This section describes the types of traffic shapers and how to configure them in the GUI and the CLI.

To configure traffic shaping in the GUI, you must enable **Traffic Shaping** in **System > Feature Visibility**.

Traffic shaping options

When you configure traffic shaping for your network, you can use the following methods to control the flow of network traffic to ensure that the traffic you want gets through, while also limiting bandwidth for less important traffic or traffic that consumes a lot of bandwidth.

- **Shared policy shaping** - bandwidth management by security policies
- **Per-IP shaping** - bandwidth management by user IP addresses
- **Application control shaping** - bandwidth management by application

Traffic shapers allow you to define how traffic will flow by setting the traffic priority, bandwidth, and DSCP options. You create shared policy traffic shapers and per-IP traffic shapers under Policy & Objects > Traffic Shapers.

You then enable traffic shapers within the traffic shaping policy, under Policy & Objects > Traffic Shaping Policy.

You can apply application control shaping to any traffic shaping policy, under Policy & Objects > Traffic Shaping Policy. You can control traffic by application category, application, and URL category.

To apply application control shaping, you must first enable application control at the policy level, under Policy & Objects > IPv4 Policy.

Traffic shaping policies allow you to apply traffic shaping measures to any traffic that matches your criteria. The criteria must specify a source, destination, service, and outgoing interface. Also, you must enable at least one type of traffic shaper to create a traffic shaping policy.

You can enable traffic shaping options on a FortiGate at the same time within a single traffic shaping policy. Generally, the hierarchy for traffic shapers in FortiOS is:

- Application control traffic shaper
- Shared policy traffic shaper
- Per-IP traffic shaper

Within this hierarchy, if an application control list has a traffic shaper defined, it has precedence over any other policy traffic shaper. For example, the Facebook application control example in [Application control shaping on page 2800](#) supersedes any security policy enabled traffic shapers. While the Facebook application may reach its maximum bandwidth, the user can still have the bandwidth room available from the shared traffic shaper and, if enabled, the per-IP traffic shaper.

Equally, any security policy shared traffic shaper has precedence over any per-IP traffic shaper. However, traffic that exceeds any of these traffic shapers is dropped. For example, the policy traffic shaper takes effect first, but if the per-IP traffic shaper limit is reached first, the traffic for that user is dropped even if the shared traffic shaper limit for the policy hasn't been exceeded.

Shared policy traffic shaping

Traffic shaping by security policy allows you to control the maximum and guaranteed throughput for any security policies specified in the traffic shaping policy.

When you configure a traffic shaper, you can apply bandwidth shaping per policy or for all policies. Depending on your selection, the FortiGate applies the traffic shaping rules differently.

By default, shared traffic shapers apply traffic shaping evenly to all policies that use. For **Per policy** and **All policies using this shaper** options to appear in the GUI, you must first enable it in the CLI. Go to Policy & Objects > Traffic Shapers and right-click on the traffic shaper to edit it in the CLI. Enter the following CLI commands:

```
set per-policy enable
end
```

Per policy

When you select a shared traffic shaper to be per policy, the FortiGate applies the traffic shaping rules to each security policy individually.

For example, if a traffic shaper is set to per policy with a maximum bandwidth of 1000 Kb/s and applied to four security policies, each policy has the same maximum bandwidth of 1000 Kb/s.

Per policy traffic shaping is compatible with client/server (active-passive) transparent mode WAN optimization rules. Traffic shaping is ignored for peer-to-peer WAN optimization and for client/server WAN optimization not operating in transparent mode.

For all policies using a traffic shaper

When you select a shared shaper to apply to all policies - **All Policies using this shaper** - the FortiGate applies the traffic shaping rules to all policies using the same shaper. For example, a traffic shaper is set to be per policy with a maximum bandwidth of 1000 Kbps. There are four security policies monitoring traffic through the FortiGate. All four have the traffic shaper enabled. Each security policy must share the defined 1000 Kbps, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kbps, the remaining three must share 200 Kbps. As policy 1 uses less bandwidth, it's opened up to the other policies to use as required. Once used, any other policies encounters latency until free bandwidth opens from a policy currently in use.

Maximum and guaranteed bandwidth

The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the traffic shaper.

The **Maximum Bandwidth** can be set to a value of between 1 and 16776000 Kbps. The GUI gives an error if any value outside of this range is used, but in the CLI a value of 0 can be entered. Setting `maximum-bandwidth` to 0 (zero) prevents any traffic from going through the policy.

The guaranteed bandwidth ensures there's a consistent reserved bandwidth available for a given service or user. When setting the guaranteed bandwidth, ensure that the value is significantly less than the bandwidth capacity of the interface, otherwise no other traffic will pass through the interface or very little and potentially causing unwanted latency.

Traffic priority

Select a traffic priority of high, medium, or low, so the FortiGate manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server that needs to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority. The firewall provides bandwidth to low-priority connections only when bandwidth isn't needed for high-priority connections.

Be sure to enable traffic shaping on all security policies. If you don't apply a traffic shaping rule to a policy, the policy is set to high priority by default. Distribute security policies over all three priority queues.

Traffic shaping policy order

You must also place the traffic shaping policies in the correct order in the traffic shaping policy list page to get the desired results. It's necessary to arrange your traffic shaping policies into a sequence that places your more granular policies above general Internet access policies. For example, you should place any policies with application control shaping at the top of the traffic shaping policy list, followed by more general traffic shaping policies with shared policy shapers and per-IP traffic shapers.

The policy list page is located under Policy & Objects > Traffic Shaping Policy. To change the order of the policies, select the far left column to move the policy up or down. Make sure that the **Seq.#** column is showing on your menu so you can easily verify a policy's position in the sequence.

The following example shows how to order your policies. The high priority VoIP traffic shaping policy is placed at the top of the list, followed by restrictive policies to control streaming media, and your general Internet access policy last.

Seq.#	Source Address	Destination	Outgoing Interface	Shared Shaper	Reverse Shaper	Service	Application	Application Category
IPv4 (1 - 4)								
1	• all	• all	• wan1	guarantee-100kbps	guarantee-100kbps	• ALL	• SIP	• VoIP
2	• all	• all	• wan1	limited_bandwidth	limited_bandwidth	• ALL	• Vimeo • YouTube	• Video/Audio
3	• all	• all	• wan1	high-priority	high-priority	• ALL		

Traffic shaping policy configuration settings

To configure a traffic shaping policy, go to Policy & Objects > Traffic Shaping Policy and select the **Create New +** sign to create a new traffic shaping policy.

Set the **Matching Criteria** to the default options shown below or specify the criteria so that it matches a specific security policy.

Source	*all (default)
Destination	*all (default)
Service	*ALL (default)
Application Category	- Choose an application category to apply traffic shaping to a specific category of applications. For example, P2P, Social.Media, or VoIP.
Application	- Choose an application to specify which applications you want to apply traffic shaping to. For example, YouTube, Vimeo, or Facebook.
URL Category	- Choose a URL category to block a subset of applications. For example, potentially liable websites, security risks, or bandwidth consuming services.

Set **Apply shaper** to the following:

Outgoing Interface	*any (Set this to the external interface that you want to apply traffic shaping to. For example, wan1 is often used.)
Shared Shaper	Choose one of the default shared traffic shapers: guarantee-100kbps, high-priority, medium-priority, low-priority, shared-1M-pipe or create your own under Policy & Objects > Traffic Shapers. Shared traffic shapers share the allotted bandwidth with any security policies using them (unless they're set to per-policy in the CLI). This affects uploads or outbound traffic.
Reverse Shaper	Choose one of the default shared traffic shapers: guarantee-100kbps, high-priority, medium-priority, low-priority, shared-1M-pipe, or create your own under Policy & Objects > Traffic Shapers. This affects downloads or inbound traffic.
Per-IP Shaper	Enable a per-IP traffic shaper if you want to apply traffic shaping by bandwidth management by user IP addresses. You create traffic shapers under Policy & Objects > Traffic Shapers. Per-IP shapers affect downloads and uploads.
Enable this policy	Policies are enabled by default, but if you want to disable a traffic shaping policy de-select it here.

To create the traffic shaping policy - CLI:

```
config firewall shaping-policy
edit <shaping_policy_ID>
```

```

set srcaddr <source_address>
set dstaddr <destination_address>
set service <service_name>
set schedule {always | none}
application <application_name>
app-category <application_category_ID_list>
url-category <URL_category_ID_list>
dstintf <destination_interface_list>
traffic-shaper <shared_shaper_name>
traffic-shaper-reverse <reverse_traffic_shaper_name>
per-ip-shaper <per_IP_shaper_name>
end

```

VLAN, VDOM, and virtual interfaces

Policy-based traffic shaping doesn't use queues directly. It shapes the traffic and if the packet is allowed by the security policy, a priority is assigned. That priority controls what queue the packet is put in upon egress. VLANs, VDOMs, aggregate ports, and other virtual devices don't have queues and, as such, traffic is sent directly to the underlying physical device where it's queued and affected by the physical ports. This is also the case with IPsec connections.

Shared traffic shaper configuration settings

To configure a shared traffic shaper go to **Policy & Objects > Traffic Shapers** and select the **Create New +** sign to create a new traffic shaper.

Type	Select Shared .
Name	Enter a name for the traffic shaper.
Apply Shaper	<p>When selecting a traffic shaper to be Per Policy, the FortiGate applies the traffic shaping rules defined to each security policy individually. For example, if a traffic shaper is set to per policy, with a maximum bandwidth of 1000 Kbps, any security policies that have that traffic shaper enabled get 1000 Kbps of bandwidth each.</p> <p>When selecting a traffic shaper to apply to all policies (For All Policies Using This Shaper), the FortiGate applies the traffic shaping rules to all policies using the same traffic shaper. For example, the traffic shaper is set to be per policy with a maximum bandwidth of 1000 Kbps. There are four security policies monitoring traffic through the FortiGate. All four have the traffic shaper enabled. Each security policy must share the defined 1000 Kbps, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kbps, the remaining three must share 200 Kbps. As policy 1 uses less bandwidth, that open bandwidth becomes available to the other policies to use as required. Once used, any other policies encounter latency until free bandwidth opens from a policy currently in use.</p>

Traffic Priority	<p>Select level of importance Priority so the FortiGate manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server needed to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority.</p> <p>If you don't apply any traffic shaping priority, the priority is set to high priority, by default.</p>
Maximum Bandwidth	<p>The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number provides a larger or smaller throughput depending on the priority you set for the traffic shaper.</p> <p>Setting Maximum Bandwidth to 0 provides unlimited bandwidth.</p>
Guaranteed Bandwidth	<p>The guaranteed bandwidth ensures that a consistent reserved bandwidth is available for a given service or user. Ensure that you set the bandwidth to a value that's significantly less than the bandwidth capacity of the interface. Otherwise, little to no traffic passes through the interface and potentially causes unwanted latency.</p> <p>Setting Guaranteed Bandwidth to 0 provides unlimited bandwidth.</p>
DSCP	<p>Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see Traffic shaping methods.</p>

Shared traffic shaper per policy example

The following steps create a per policy traffic shaper called "Throughput" with a maximum traffic amount of 720,000 Kbps, and a guaranteed traffic of 150,000 Kbps with a high traffic priority.

To create the shared traffic shaper - GUI:

1. Go to **Policy & Objects > Traffic Shapers** and select the **Create New** + sign.
2. Set the **Type** to **Shared**.
3. Enter the **Name** *Throughput*.
4. Set the **Apply shaper** field to **Per Policy**.

By default, shared traffic shapers apply traffic shaping evenly to all policies that use it. For **Per policy** and **All policies using this shaper** options to appear in the GUI, you must first enable it in the CLI. Go to Policy & Objects > Traffic Shapers and right-click on the traffic shaper to edit it in the CLI. Enter the following CLI commands:

```
set per-policy enable
end
```

5. Set the **Traffic Priority** to **High**.
6. Select the **Maximum Bandwidth** check box and enter the value 150000.
7. Select the **Guaranteed Bandwidth** check box and enter the value 120000.
8. Select **OK**.

To create the shared shaper - CLI:

```
config firewall shaper traffic-shaper
edit Throughput
set per-policy enable
set maximum-bandwidth 150000
set guaranteed-bandwidth 120000
set priority high
end
```

Per-IP traffic shaping

Traffic shaping by IP allows you to apply traffic shaping to all source IP addresses in the security policy. In addition to controlling the maximum bandwidth users of a selected policy, you can also define the maximum number of concurrent sessions.

Per-IP traffic shaping allows you to limit the behavior of every member of a policy to avoid having one user use all of the available bandwidth. The bandwidth is shared equally within a group. Using a per-IP traffic shaper avoids having to create multiple policies for every user you want to apply a traffic shaper. Per-IP traffic shaping isn't supported over NP2 interfaces.

Per-IP traffic shaping configuration settings

To configure per-IP traffic shaping go to **Policy & Objects > Traffic Shapers > Per-IP** and select the **Create New** + sign.

Type	Select Per-IP .
Name	Enter a name for the per-IP traffic shaper.
Maximum Bandwidth	<p>The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the traffic shaper.</p> <p>Setting Maximum Bandwidth to 0 (zero) provides unlimited bandwidth.</p>

Maximum Concurrent Connections	Enter the maximum allowed concurrent connections.
Forward DSCP Reverse DSCP	Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see Traffic shaping methods .

Example

The following steps create a per-IP traffic shaper called “Accounting” with a maximum traffic amount of 720,000 Kbps, and the number of concurrent sessions of 200.

To create the shared shaper - GUI:

1. Go to **Policy & Objects > Traffic Shapers** and select the **Create New** “Plus” Icon.
2. Set the **Type** to **Per-IP**.
3. Enter the **Name** *Accounting*.
4. Enable the **Maximum Bandwidth** and enter the value *720000*.
5. Enable the **Maximum Concurrent Sessions** and enter the value *200*.
6. Select **OK**.

To create the shared shaper - CLI:

```
config firewall shaper per-ip-shaper
edit Accounting
set max100-bandwidth 720000
set max-concurrent-session 200
end
```

Adding a per-IP traffic shaper to a traffic shaping policy

Per-IP traffic shaping is supported by IPv6 security policies. You can add any per-IP traffic shaper to an IPv6 security policy in the CLI.

Example

The following steps show you how to add an existing per-IP traffic shaper to an IPv6 security policy. Make sure that you have already created a per-IP traffic shaper under Policy & Objects > Traffic Shapers.

To add a per-IP traffic shaper to an IPv6 security policy - GUI:

1. Go to **Policy & Objects > IPv6 Policy** and click the **Create New** + icon to create an Internet access policy.
2. Set the following:

Name	Enter a descriptive name
Incoming Interface	Internal
Source address	All
Outgoing interface	wan1
Destination address	all
Schedule	Always
Service	Any
Action	Accept

3. Select **OK**.
4. Go to Policy & Objects > Traffic Shaping Policy and the **Create New** + icon to create a new traffic shaping policy.
5. To apply your traffic shaping policy to the security policy you created earlier set the **Matching Criteria** to the following:

Source	all
Destination address	all
Service	ALL
Application Category	-
Application	-
URL Category	-

6. Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you want to apply traffic shaping to.)
Shared Shaper	-
Reverse Shaper	-
Per-IP Shaper	Enable Per-IP Shaper and select your traffic traffic shaper from the drop-down menu.
Enable this policy	Enable this policy

7. Select **OK**.
8. On the policy list page, move the per-IP traffic shaper to the top of the list by clicking on the far left column to drag and drop it.

There are two methods to configure traffic shaping in the CLI. You can add a per-IP traffic shaper directly to an IPv6 security policy, or you can add a per-IP shaper to a traffic shaping policy. The second method will allow you to apply traffic shaping based on the interface and can therefore affect multiple security policies easily. The first method requires that you enable traffic shaping individually in all policies using the same two interfaces.

To add a per-IP traffic shaper to an IPv6 security policy- CLI:

```
config firewall policy6
  edit <security_policy_ID_number>
    set per-ip-shaper <per_IP_shaper_name>
  end
```

To add a per-IP traffic shaper to an IPv6 traffic shaping policy - CLI:

```
config firewall shaping-policy
  edit 1 <security_policy_ID_number>
    set ip-version 6
    set srcaddr <source_address>
    set dstaddr <destination_address>
    set service <service_name>
    set dstintf <outgoing_interface>
    set per-ip-shaper <per_IP_shaper_name>
  end
```

Application control shaping

Traffic shaping is also possible for specific applications. Application control shaping works in conjunction with a shared traffic shaper or per-IP traffic shaper. You must create a traffic shaper with the bandwidth settings you would like to enforce or edit one of the predefined traffic shapers in the Policy & Objects > Traffic Shapers menu.

Traffic shaping policies allow you to enable these traffic shapers and configure application control options. In the traffic shaping policy, you can set an **Application Category**, **Application**, and **URL Category**. You must also specify which security policies to apply your traffic shaper to by setting the **Matching Criteria**. You can create a traffic shaping policy in the Policy & Objects > Traffic Shaping Policy section.

For application control shaping to work, application control must be enabled in a security policy, through Policy & Objects > IPv4 Policy or Policy & Objects > IPv6 Policy under **Security Profiles**.

Also, application control traffic shaping affects only applications that are set to pass in the Security Profiles > Application Control menu.

For more information about application control, see the FortiOS [Chapter 21 - Security Profiles](#) Guide.

Example

This example sets the traffic shaping definition for Facebook to a medium priority, a default traffic shaper.

To add traffic shaping for Facebook - GUI:

1. Go to Policy & Objects > IPv4 Policy to create a general Internet access security policy.
2. Select the **Create New** + icon in the upper right corner of the screen to create a new security policy (or edit an

existing Internet access policy).

- Set the following to enable application control within a security policy:

Name	<Enter a descriptive name.>
Incoming Interface	Internal
Source address	All
Outgoing interface	wan1
Destination address	all
Schedule	Always
Service	Any
Action	Accept
Application Control	Under Security Profiles, enable Application Control and select the default application control profile.

- Select **OK**.
- Go to Policy & Objects > Traffic Shaping Policy and the **Create New** + icon to create a new traffic shaping policy.
- To apply your traffic shaping policy to the security policy you created earlier, set the **Matching Criteria** to the following:

Source	all
Destination address	all
Service	ALL
Application Category	Social.Media
Application	Facebook
URL Category	Social Networking

- Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you want to apply shaping to.)
Shared Shaper	Enable Shared Shaper and select medium-priority from the drop-down menu.
Reverse Shaper	Enable Shared Shaper and select medium-priority from the drop-down menu.
Enable this policy	Enable this policy.

8. Select **OK**.
9. On the policy list page, move the Facebook traffic shaping policy to the top of the list by clicking on the far left column to drag and drop it.

To create a traffic shaping policy for Facebook - CLI:

```
config firewall shaping-policy
edit 1 <shaping_policy_ID_number>
set srcaddr all
set dstaddr all
set service ALL
set application 15832
set app-category 23 <Social.Media>
set url-category 37 <Social Networking>
set dstintf wan1 <outgoing_interface>
set traffic-shaper medium-priority
set reverse-traffic-shaper medium-priority
end
```

Reverse direction traffic shaping

The traffic shaper you select in the traffic shaping policy (shared traffic shaper) affects the traffic in the direction defined in the policy. For example, if the source port is lan and the destination is wan1, the traffic shaping affects the flow in this direction only — affecting the upload speed of the outbound traffic. By selecting **Shared Traffic Shaper Reverse Direction**, you can define the traffic shaper for the policy in the opposite direction to affect the download speed of the inbound traffic. In this example, from wan 1 to lan.

To add a reverse shaper - GUI:

1. Go to Policy & Objects > Traffic Shaping Policy.
2. Click **Create New** or select an existing policy and click **Edit**.
3. Set the **Matching Criteria** to match the interfaces of any security policies you want to affect.
4. Navigate to the **Apply shaper** section, enable the **Shared Shaper**, and select a traffic shaper from the drop-down menu.
5. Enable the **Reverse Shaper** and select a traffic shaper from the drop-down menu.
6. Select **OK**.

Setting the reverse direction only

There may be instances where you only need traffic shaping for incoming connections, which is in the reverse direction of typical traffic shapers.

To add a reverse traffic shaper - GUI:

1. Go to Policy & Objects > Traffic Shaping Policy.
2. Click **Create New** or select an existing policy and click **Edit**.
3. Set the **Matching Criteria** to match the interfaces of any security policies you want to affect.
4. Navigate to the **Apply shaper** section, enable the **Reverse Shaper** and select a traffic shaper from the drop-down menu.
5. Select **OK**.

To configure a reverse-only traffic shaper in a traffic shaping policy - CLI:

```
config firewall shaping-policy
  edit <policy_number>
    set reverse-traffic-shaper medium-priority
  end
```

To configure a reverse-only shaper within a security policy - CLI:

```
config firewall policy
  edit <policy_number>
    ...
    set traffic-shaper-reverse <shaper_name>
  end
```

Enabling traffic shaping in the security policy

Historically, FortiOS traffic shapers have always been enabled within a security policy. This is no longer the easiest way to apply traffic shapers, since in FortiOS 5.4 traffic shaping is now configured in the traffic shaping policy section, under Policy & Objects > Traffic Shaping Policy. However, you can still enable traffic shapers within a security policy using CLI commands and it will then appear in the GUI afterwards. The traffic shapers always go into effect after any DoS detection policies, and before any routing or packet scanning occurs.

Traffic shaping is also supported for IPv6 policies.

This isn't the recommended method, as it's easier to keep track of and order your traffic shaping policies if you configure them within a traffic shaping policy.

To enable traffic shaping within a security policy - CLI:

```
config firewall policy
  edit <policy_number>
    ...
    set traffic-shaper <traffic_shaper_name>
    set reverse-traffic-shaper <traffic_shaper_name>
    set per-ip-shaper <per_IP_traffic_shaper_name>
  end
```

Shared traffic shapers affect outbound traffic heading to a destination. To affect inbound traffic, or downloads, enable the **Reverse Shaper** also. For more information, see ["Reverse direction traffic shaping" on page 2802](#).

Scheduling traffic shaping policies

In FortiOS 5.6.3, a new scheduling feature was added to traffic shaping policies to apply different traffic shaping profiles at different times. This "schedule" attribute is currently only available using the CLI, and you can use this feature to apply a recurring schedule to your traffic shaping policies. The default recurring schedule options available are **always** or **none**. You can also create new schedules or schedule groups under **Policy & Objects > Schedules**. This allows you to create custom recurring or one-time schedules that can then be applied to your traffic shaping policies using the CLI commands below.

To schedule traffic shaping policies - CLI:

```
config firewall shaping-policy
edit <shaping_policy_ID>
set schedule {always | none}
end
```

ToS priority

Type of service (ToS) is an 8-bit field in the IP header that allows you to determine how the IP datagram should be delivered, using criteria of delay, throughput, priority, reliability, and cost. Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority ToS is 0, and the highest is 7 when bits 3, 4, and 5 are all set to 1. There are other seldom used or reserved bits that aren't listed here.

Together these bits are the ToS variable of the `tos-based-priority` command. The router tries to match the ToS of the datagram to the ToS on one of the possible routes to the destination. If there's no match, the datagram is sent over a zero ToS route. Using increased quality may increase the cost of delivery because better performance may consume limited network resources.

Each bit represents the priority as defined in [RFC 1349](#):

- 1000 - minimize delay
- 0100 - maximize throughput
- 0010 - maximize reliability
- 0001 - minimize monetary cost

To set the ToS value - CLI:

```
config system tos-based-priority
edit <sequence_number>
set tos [0-15]
set priority {high | medium | low}
end
```

Where `tos` is the value of the type of service bit in the IP datagram header with a value between 0 and 15, and `priority` is the priority of this type of service priority. These priority levels conform to the firewall traffic shaping priorities, as defined in [RFC 1349](#).

For example, if you want to configure a FortiGate so that reliability is the first priority, set the ToS value to 4.

```
config system tos-based-priority
edit 1
set tos 4
set priority high
end
```

For a list of ToS values and their DSCP equivalents see [Traffic shaping methods on page 2791](#).

Example

```
config system tos-based-priority
edit 1
set tos 1
```

```
        set priority low
    next
    edit 4
        set tos 4
        set priority medium
    next
    edit 6
        set tos 6
        set priority high
    next
end
```

ToS in FortiOS

Traffic shaping and ToS follow the following sequence:

- The CLI command `tos-based-priority` acts as a `tos-to-priority` mapping. FortiOS maps the ToS to a priority when it receives a packet.
- Traffic shaping settings adjust a packet's priority according to the traffic.
- Deliver the packet based on its priority.

Traffic shaping units of measurement

Bandwidth speeds are measured in Kilobits per second (Kbps), and Bytes that are sent and received are measured in megabytes (MB). Occasionally this can cause confusion depending on whether your ISP uses kilobits per second (Kbps), kilobytes per second (KBps), megabits per second (Mbps), or gigabits per second (Gbps).

Download speeds

- 1 kilobyte per second (KBps) = 8 kilobits per second (Kbps)
- 1 megabit per second (Mbps) = 1,000,000 bits per second (bps)
- 1 gigabit per second (Gbps) = 1,000 (Mbps)

File sizes

- 1 megabyte (MB) = 1,024 kilobytes (KB)
- 1 gigabyte (GB) = 1,024 megabytes (MB) or 1,048,576 kilobytes (KB)

To change a traffic shaper's unit of measurement - CLI:

```
config firewall shaper traffic-shaper
    edit <traffic_shaper_name>
        set bandwidth-unit {kbps | mbps | gbps}
    end
```

Interface-based traffic shaping

You can enable traffic shaping on an interface. This allows you to enforce bandwidth limits for individual interfaces, by percentage. To configure interface-based traffic shaping, you must classify traffic in a traffic shaping policy, assign bandwidth percentages in a traffic shaping profile, and apply the traffic shaping profile as the egress traffic shaper on an interface.

Currently, only egress traffic shaping is available. To achieve ingress traffic shaping, you can typically configure egress traffic shaping on the alternate interface. For example, if you want to control inbound traffic on the WAN interface of the FortiGate, you can apply outbound traffic shaping to the LAN interface.

Classifying traffic

You can use a traffic shaping policy to classify traffic. Edit a traffic shaping policy using the `config firewall shaping-policy` command, and set the `class-id` command. A FortiGate stores the `class-id` on the kernel session, so that it can quickly categorize any traffic that matches the criteria you define in the traffic shaping policy.

To set the traffic class - CLI:

```
config firewall shaping-policy
  edit <shaping_policy_ID>
    ...
    set class-id <value>
  next
end
```

where `class-id` is a value in the range of 2 to 31.

Assigning bandwidth percentages

You can assign bandwidth percentages, using the `config firewall shaping-profile` command. Set a bandwidth guarantee using the `guaranteed-bandwidth-percentage` command and set a maximum bandwidth using the `maximum-bandwidth-percentage`.

To assign bandwidth percentages in a traffic shaping profile - CLI:

```
config firewall shaping-profile
  edit <egress_shaper_name>
    set default-class-id 2
    config shaping-entries
      edit 1
        set class-id 2
        set priority low {low | medium | high}
        set guaranteed-bandwidth-percentage 3
        set maximum-bandwidth-percentage 50
      next
      edit 3
        set class-id 5
        set priority low {low | medium | high}
        set guaranteed-bandwidth-percentage 3
        set maximum-bandwidth-percentage 50
      next
    end
  end
end
```

where you set the following variables:

Variable	Description
<code>default-class-id</code>	<p>The default class ID handles unclassified packets, including all local traffic. You must define the default class ID, since unclassified traffic must be controlled.</p> <p>Note that any traffic class that's defined in the traffic shaping policy, but isn't defined in the traffic shaping profile, is classified as part of the default class ID.</p>
<code>class-id</code>	The <code>class-id</code> is a value in the range of 2 to 31.
<code>priority</code>	The <code>priority</code> assigned (low, medium, high) to the class also plays a critical role in the bandwidth algorithm. Basically, priority decides which class can win when multiple classes compete for the available bandwidth on the interface.
<code>guaranteed-bandwidth-percentage</code>	<p>The <code>guaranteed-bandwidth-percentage</code> is a value in the range of 0 to 100 percent. The guaranteed bandwidth reserves a set amount of bandwidth for the class of traffic you select.</p> <p>For example, if you set the <code>guaranteed-bandwidth-percentage</code> to 3, then the FortiGate assigns at least 3% of the total bandwidth on the interface to that traffic class (as long as the current traffic volume of this class is more than 3% of the total volume). If the current traffic volume of this class is less than 3% of the total bandwidth of the interface, then it's not shaped.</p>
<code>maximum-bandwidth-percentage</code>	<p>The <code>maximum-bandwidth-percentage</code> is a value in the range of 0 to 100 percent. The maximum bandwidth defines the hard limit for traffic in that class. The class never has more bandwidth than the amount of bandwidth you define. You can assign 100% as the value, so that the class can potentially take all of the bandwidth of the designated interface.</p>

Important requirements:

- The `guaranteed-bandwidth-percentage` of the default class (in this example, class-id 2) must be greater than or equal to 1%. This ensures that local traffic always has some guaranteed bandwidth. However, the `guaranteed-bandwidth-percentage` of other classes can be 0.
- The `guaranteed-bandwidth-percentage` must not exceed the value of the `maximum-bandwidth-percentage`.
- The sum of `guaranteed-bandwidth-percentage` of all entries in one profile must not exceed 100%.

Apply the traffic shaping profile

You can apply the egress traffic shaper to an interface, using the `config system interface` command to edit the interface of your choice. Then, set the `inbandwidth` and `outbandwidth` values to the total amount of bandwidth that's available on the interface. Set the `egress-shaping-profile` to the traffic shaping profile you want to apply.

To apply the egress shaper to an interface - CLI:

```

config system interface
  edit <interface-name>
    set inbandwidth <limit>
    set outbandwidth <limit>
    set egress-shaping-profile <egress_shaper_name>
  next
end

```

where the `inbandwidth` and `outbandwidth` value is the total amount of bandwidth that's available on the interface, from a value in the range of 0 to 1677600 kbps.

You should set the `egress-shaping-profile` value to the traffic shaping profile you want to apply.

Example of competing priority classes

The following example can help you understand how the bandwidth algorithm uses both the class ID, and priority settings to determine which class wins when there are competing traffic classes. These examples are based on the assumption that the traffic volume of each class is larger than its allocated bandwidth.

NOTE: If a class has a small traffic volume, other classes can borrow unused bandwidth from it. In the following example, if class 2 has 100 MB of traffic and class 3 has 1 GB of traffic, then you should set the bandwidth for class 2 to 100 MB and for class 3 to 900 MB.

Class	Priority	guaranteed-bandwidth-percentage (%)	maximum-bandwidth-percentage (%)
2	high	20%	100%
3	low	20%	100%

If the profile configuration matches the table above, and the profile is applied to an egress interface with a total bandwidth of 1 GB, and both class 2 and class 3 have 1 GB of generated traffic, the results are the following:

Class	Priority	Actual bandwidth
2	high	80% of 1 GB (800 MB)
3	low	20% of 1 GB (200 MB)

The reason for the results are that both class 2 and 3 are assigned guaranteed bandwidth first, which is 200 MB each (20% of 1 GB). The remaining bandwidth of 600 MB is then allocated to class 2, because it has a higher priority.

The algorithm can get a bit more complex when you assign multiple classes with the same priority. When the same priority classes compete for available bandwidth, the allocation to each class is proportional to its `guaranteed-bandwidth-percentage`.

Here's a slightly more complex example:

Class	Priority	guaranteed-bandwidth-percentage (%)	maximum-bandwidth-percentage (%)
2	high	20%	100%
3	low	20%	100%
4	high	30%	100%

If the profile configuration matches the table above, and is attached to an egress interface with a total bandwidth of 1 GB, and classes 2, 3, and 4 have 1 GB of traffic generated, the results are the following:

Class	Priority	Actual bandwidth
2	high	200MB + 120MB = 320MB
3	low	200MB + 0 = 200MB
4	high	300MB + 180MB = 480MB

The reason for the results are that all classes are assigned the guaranteed bandwidth first, which is 200 MB, 200 MB, and 300 MB respectively. The remaining bandwidth of 300 MB is then allocated to class 2 and class 4, because of their higher priority settings. The allocation for the remaining 300MB is proportional to their guaranteed bandwidth. In this case, it is 120 MB for class 2 ($300 \text{ MB} * 20 / 50$) and 180MB for class 4 ($300 \text{ MB} * 30 / 50$).

Internet services support

The Internet Service Database (ISDB) and IP Reputation Database (IRDB) enhance traffic shaping criteria for traffic shaping policies.

To use Internet services in a traffic shaping policy, you must set the **Source** or **Destination** to one of the Internet services listed in the **Internet Service** tab. Internet service sources include **CloudServer-AWS**, **Proxy-Proxy.Server**, **SearchBot-Bing**, and more. Internet service destinations offer a wide range of services, such as **Github-Web**, **Salesforce-SMTP**, and **Netflix-DNS**.

The following image of the Traffic Shaping Policy page shows you where to find the **Internet Service** tab:

To create a traffic shaping policy that uses Internet services - GUI:

1. Create a new traffic shaping policy under **Policy & Objects > Traffic Shaping Policy**.
2. Add the **Internet Service** of your choice to the **Source** and **Destination** by selecting from the **Internet Service** tab on the far right.
3. Set the **Outgoing Interface** to the egress port that traffic passes through.

To create a traffic shaping policy that uses Internet services - CLI:

```
config firewall shaping-policy
  edit <shaping_policy_ID>
    set internet-service {enable | disable}
    set internet-service-id <service_ID>
    set internet-service-custom <custom_Internet_service_name>
    set internet-service-src {enable | disable}
    set internet-service-src-id <Internet_service_source_ID>
    set internet-service-src-custom <custom_Internet_service_source_name>
  next
end
```

where you set the following variables:

Option	Description
<code>internet-service</code>	Enables or disables the use of Internet services for this policy. If enabled, the FortiGate uses the Internet service destination address and service.

Option	Description
<code>internet-service-id</code>	The Internet service ID. For example: <ul style="list-style-type: none"> • 65536 Google-Others • 65537 Google-Web
<code>internet-service-custom</code>	Enter a custom Internet service name.
<code>internet-service-src</code>	Enables or disables the use of Internet services in source for this policy. If enabled, the FortiGate uses the Internet Services source address.
<code>internet-service-src-id</code>	The Internet service source ID. For example: <ul style="list-style-type: none"> • 65536 Google-Others • 65537 Google-Web
<code>internet-service-src-custom</code>	The custom Internet service source name. NOTE: This custom name must already be configured.

For more information about ISDB support in Firewall policies, see the ["Firewall policies"](#) on page 529 or *Networking Handbook*.

Differentiated services

Differentiated services (DiffServ) describes a set of end-to-end Quality of Service (QoS) capabilities. End-to-end QoS is the ability of a network to deliver service required by specific network traffic from one end of the network to another. By configuring differentiated services, you configure your network to deliver particular levels of service for different packets based on the QoS specified by each packet.

DiffServ is defined by RFC 2474 and 2475 as enhancements to IP networking to enable scalable service discrimination in the IP network without the need for per-flow state and signaling at every hop. Routers that can understand differentiated services sort IP traffic into classes by inspecting the DS field in IPv4 header or the Traffic Class field in the IPv6 header.

You can use the FortiGate DiffServ feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet.

If the differentiated services feature isn't enabled, the FortiGate treats traffic as if the DSCP value is set to the default (00) and won't change the DSCP field of IP packets. DSCP values are also not applied to traffic if the traffic originates from a FortiGate itself.

The FortiGate applies the DSCP value and IPsec encryption to the differentiated services (formerly ToS) field in the first word of the IP header. The typical first word of an IP header, with the default DSCP value, is 4500:

- 4 for IPv4
- 5 for a length of five words
- 00 for the default DSCP value

You can change the packet's DSCP field for traffic initiating a session (forward) or for reply traffic (reverse) and enable each direction separately and configure it in the security policy.

Changes to DSCP values in a security policy effect new sessions. If traffic must use the new DSCP values immediately, clear all existing sessions.

To enable DSCP - CLI:

```
config firewall policy
  edit <policy_number>
    ...
    set diffserv-forward enable
    set diffservcode-forward <binary_integer>
    set diffserv-reverse enable
    set diffservcode-rev <binary_integer>
  end
```

For more information on the different DSCP commands, see the examples below and the CLI Reference. If you only set `diffserv-forward` and `diffserv-reverse` without setting the corresponding `diffservcode` values, the FortiGate resets the bits to zero.

For a list of DSCP values and their ToS equivalents see [Differentiated services on page 2811](#). DSCP values can also be defined within a shared traffic shaper as a single value, and per-IP traffic shaper for forward and reverse directions.

DSCP examples

For all the following DSCP examples, the FortiGate and client PC configuration is the following diagram and used firewall-based DSCP configurations.

Example

In this example, an ICMP ping is executed between User 1 and FortiGate B, through a FortiGate. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
```

```

set srcintf port6
set dstintf port3
set src addr all
set dstaddr all
set action accept
set schedule always
set service ANY
set diffserv-forward enable
set diffservcode-forward 101110
end

```

As a result, FortiGate A changes the DSCP field for outgoing traffic, but not to its reply traffic. The binary DSCP values used map to the following hexadecimal.

ToS field values, which are observable by a sniffer (also known as a packet tracer):

- DSCP 000000 is TOS field 0x00
- DSCP 101110 is TOS field 0xb8, the recommended DSCP value for expedited forwarding (EF)

If you perform an ICMP ping between User 1 and User 2, the following output illustrates the IP headers for the request and the reply by sniffers on each of the network interfaces on the FortiGate. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.

Example

In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

```

config firewall policy
edit 2
set srcintf port6
set dstintf port3
set src addr all
set dstaddr all
set action accept
set schedule always
set service ANY"
set diffserv-forward enable
set diffserv-rev enable
set diffservcode-forward 101110
set diffservcode-rev 101111
end

```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic. The binary DSCP values in map to the following hexadecimal ToS field values, which are observable by a sniffer:

- DSCP 000000 is TOS field 0x**00**
- DSCP 101110 is TOS field 0x**b8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0x**bc**

If you perform an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of the network interfaces on FortiGate A and FortiGate B. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.

Example

In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```

config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
  end

```

FortiGate B contains the following configuration:

```

config firewall policy
  edit 2
    set srcintf wan2
    set dstintf internal
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-rev enable
    set diffservcode-rev 101101
  end

```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, and FortiGate B changes the DSCP field only for reply traffic. The binary DSCP values in this configuration map to the following hexadecimal ToS field values:

- DSCP 000000 is TOS field **0x00**
- DSCP 101101 is TOS field **0xb4**
- DSCP 101110 is TOS field **0xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field **0xbc**

If you perform an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of the network interfaces on FortiGate A and FortiGate B. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.

Example

In this example, HTTPS and DNS traffic is sent from User 1 to FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
  end
```

FortiGate B contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf wan2
    set dstintf internal
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-rev enable
    set diffservcode-rev 101101
  end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, but FortiGate B changes the DSCP field only for reply traffic which passes through its internal interface. Since the example traffic doesn't pass through the internal interface, FortiGate B doesn't mark the packets. The binary DSCP values in this configuration map to the following hexadecimal ToS field values:

- DSCP 000000 is TOS field **0x00**
- DSCP 101101 is TOS field **0xb4**, which is configured on FortiGate B but not observed by the sniffer because the example traffic originates from the FortiGate itself, and therefore doesn't match that security policy.
- DSCP 101110 is TOS field **0xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field **0xbc**

If you sent HTTPS or DNS traffic from User 1 to FortiGate B, the following would illustrate the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the ToS field, which contains the DSCP value.

Traffic mapping

There are two types of traffic mapping: Type of Service (ToS) and Differentiated Services Code Point (DSCP). You can only use one method at a time. ToS is the default method. You can set the traffic mapping type using the CLI.

To configure traffic mapping - CLI:

```
config system global
    set traffic-priority {tos | dscp}
    set traffic-priority-level {low | medium | high }
end
```

Mapping of DSCP and ToS hexadecimal values for QoS

Service class	DSCP bits	DSCP value	ToS value	ToS hexadecimal
Network Control	111000	56-63	224	0xE0
Internetwork Control	110000	48-55	192	0xC0
Critical - Voice Data (RTP)	101110	46	184	0xB8
	101000	40	160	0xA0
Flash Override Video Data	100010	34	136	0x88
	100100	36	144	0x90
	100110	38	152	0x98
	100000	32	128	0x80
	011010	26	104	0x68
Flash Voice Control	011100	28	112	0x70
	011110	30	120	0x78
	011000	24	96	0x60

Service class	DSCP bits	DSCP value	ToS value	ToS hexadecimal
Immediate Deterministic (SNA)	010010	18	72	0x48
	010100	20	80	0x50
	010110	22	88	0x58
	010000	16	64	0x40
Priority Controlled Load	001010	10	40	0x28
	001100	12	48	0x30
	001110	14	56	0x38
	001000	8	32	0x20
Routine - Best Effort	000000	0	0	0x00
Routine - Penalty Box	000010	2	8	0x08

Traffic shaper monitor

You can view statistical information about traffic shapers and their bandwidth from FortiView > Traffic Shaping.

Refresh the information on the page.

Table View shows the following columns by default: Shaper, Bytes (Sent/Received), Sessions, Bandwidth, or Dropped Bytes. For more display options, right-click on the column header.

Bubble Chart shows you which resources consume the most bandwidth. Double-click on a traffic shaper to view more details. Determine whether more granular shaping is required by looking at the bandwidth usage by sources, destinations, applications, policies, and sessions.

FortiView Settings include the following options:

- Include Local traffic (Realtime Only)
- Include Unscanned Applications (Applications View Only)
- Auto update realtime visualizations
- Interval (seconds)
- Threat Weight Settings

Examples

While it is possible to configure QoS using a combination of security policies and ToS based priorities, and to distribute traffic over all six of the possible queues for each physical interface, the results of those configurations can be more difficult to analyze due to their complexity. In those cases, prioritization behavior can vary by several factors, including traffic volume, type of service (ToS) or differentiated services (DiffServ) markings, and correlation of session to a security policy.

The following simple examples illustrate QoS configurations using either prioritization by security policy, or prioritization by ToS bit, but not both. The examples also assume you are not configuring traffic shaping for interfaces that receive hardware acceleration from network processing units (NPU).

QoS using priority from security policies

Configurations implementing QoS using the priority values defined in the security policies are capable of applying bandwidth limits and guarantees.

In addition to configuring traffic shaping, you may also choose to limit the bandwidth accepted by each interface. This can be useful in scenarios where the bandwidth received on source interfaces frequently exceeds the maximum bandwidth limit defined in the security policy. Rather than waste processing power on packets that will get dropped later in the process, you may choose to preemptively police the traffic.

If you decide to implement QoS using security policies rather than ToS bit, the FortiGate applies QoS to all packets controlled by the policy. This type of control is less granular than prioritization by ToS bit, but has the benefits of correlating quality of service to a security policy. This correlation enables you to distribute traffic over up to four of the possible 6 priority queues (queue 0 to queue 3), doesn't require other devices in your network to set or respect the ToS bit, and enables you to configure bandwidth limits and guarantees.

In the following example, we limit the bandwidth accepted by each source interface, limit the bandwidth used by sessions controlled by the security policy, and then configure prioritized queuing on the destination interface based upon the priority in the security policy, subject to alternative assignment to queue 0 when necessary to achieve the guaranteed packet rate.

To limit bandwidth accepted by an interface - CLI:

```
config system interface
  edit <interface_name>
    set inbandwidth <limit>
  next
end
```

where <rate_int> is the bandwidth limit in Kbps. Excess packets are dropped.

To configure bandwidth guarantees, limits, and priorities - GUI:

1. Go to **Policy & Objects > Traffic Shapers** and select the Create New + sign.
2. Select **Shared** or **Per-IP**.
3. Enter a name for the traffic shaper.

4. Select the **Traffic Priority**.
High has a priority value of 1, Medium is 2, and Low is 3. While the current packet rate is below Guaranteed Bandwidth, the FortiGate disregards this setting, and instead uses priority queue.
5. Enable **Max Bandwidth** and enter a value.
Packets greater than this rate are discarded.
6. Enable **Guaranteed Bandwidth** and enter a value, if any.
Bandwidth guarantees affect prioritization. While packet rates are less than this rate, they use priority queue 0. If this isn't the effect you intend, consider entering a small guaranteed rate, or enter 0 to effectively disable bandwidth guarantees.
7. Enable **DSCP** and set a value.
8. Select **OK**.

Per-IP shapers also include the option to set a maximum number of concurrent connections and to set both **Forward DSCP** and **Reverse DSCP**.

Sample configuration

This sample configuration limits ingressing bandwidth to 500 Kbps. It also applies separate traffic shapers to FTP and HTTP traffic. In addition to the interface bandwidth limit, HTTP traffic is subject to a security policy bandwidth limit of 200 Kbps.

All egressing FTP traffic greater than 10 Kbps is subject to a low priority queue (queue 3), while all egressing HTTP traffic greater than 100 Kbps is subject to a medium priority queue (queue 2). That is, unless FTP traffic rates are lower than their guaranteed rate, and web traffic rates are greater than their guaranteed rate, FTP traffic is lower priority than web traffic.

Traffic less than these guaranteed bandwidth rates use the highest priority queue (queue 0).

To set the inbandwidth limits - CLI:

This setting is only available in the CLI.

```
config system interface
  edit wan1
    set inbandwidth 500
  next
end
```

Create traffic shapers for FTP and HTTP.

To configure an FTP shaper - GUI:

1. Go to **Policy & Objects > Traffic Shapers**, and select the **Create New** "Plus" icon.
2. Select **Shared**.
3. Enter **FTP** for the name of the traffic shaper.
4. Set **Traffic Priority** to **Low**.
5. Select the **Guaranteed Bandwidth** checkbox and enter **10** Kbps.
6. Select the **Maximum Bandwidth** checkbox and enter **500** Kbps.

7. Select **OK**.
8. Select the FTP traffic shaper, right-click it, and select **Edit in CLI**. Type the following command:

```
set per-policy
end
```

To configure an HTTP shaper - GUI:

1. Select the **Create New** "Plus" icon.
2. Set **Type** to **Shared**.
3. Enter **HTTP** for the name of the traffic shaper.
4. Set **Traffic Priority** to **Medium**.
5. Select the **Guaranteed Bandwidth** checkbox and enter **100 Kbps**.
6. Select the **Maximum Bandwidth** checkbox and enter **200 Kbps**.
7. Select **OK**.
8. Select the HTTP traffic shaper, right-click it, and select **Edit in CLI**. Type the following command:

```
set per-policy
end
```

To add the FTP shaper to a traffic shaping policy - GUI:

1. Go to **Policy & Objects > Traffic Shaping Policy** and click **Create New** to create a traffic shaping policy for FTP.
2. Set the **Matching Criteria** to the following:

Source	all
Destination address	all
Service	FTP

3. Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you wish to apply shaping to.)
Shared Shaper	Enable Shared Shaper and select FTP from the drop-down menu.
Reverse Shaper	Enable Shared Shaper and select FTP from the drop-down menu.
Enable this policy	Enable this policy.

4. Select **OK**.

To add the HTTP shaper to a traffic shaping policy - GUI:

1. Go to **Policy & Objects > Traffic Shaping Policy** and click **Create New** to create a traffic shaping policy for HTTP.
2. Set the **Matching Criteria** to the following:

Source	all
Destination address	all
Service	HTTP

3. Under **Apply shaper**, set the following:

Outgoing interface	any (The outgoing interface should match the outgoing interface of the security policy you want to apply traffic shaping to.)
Shared Shaper	Enable Shared Shaper and select HTTP from the drop-down menu.
Reverse Shaper	Enable Shared Shaper and select HTTP from the drop-down menu.
Enable this policy	Enable this policy.

4. Select **OK**.
5. On the policy list page, move the FTP traffic shaping policy to the top of the list by clicking the far left column to drag and drop it. The HTTP traffic shaping policy should be below the FTP policy, and more general Internet access policies should be at the bottom of the policy list.

To configure the FTP and HTTP traffic shapers - CLI:

```
config firewall shaper traffic-shaper
  edit FTP
    set maximum-bandwidth 500
    set guaranteed-bandwidth 10
    set per-policy enable
    set priority low
  next
  edit HTTP
    set maximum-bandwidth 200
    set guaranteed-bandwidth 100
    set per-policy enable
    set priority medium
  end
```

To add each traffic shaper to a traffic shaping policy - CLI:

```
config firewall shaping-policy
  edit 1 <shaping_policy_ID_number>
    set srcaddr all
    set dstaddr all
    set service ALL
    set dstintf wan1 <outgoing_interface>
    set traffic-shaper FTP
  next
  edit 2 <shaping_policy_ID_number>
    set srcaddr all
    set dstaddr all
    set service ALL
    set dstintf wan1 <outgoing_interface>
    set traffic-shaper HTTP
```

```
next
move 1 before 2
end
```

QoS using priority from ToS or DiffServ

Configurations implementing QoS using the priority values defined in either global or specific ToS bit values are not capable of applying bandwidth limits and guarantees, but are capable of prioritizing traffic at per-packet levels, rather than uniformly to all services matched by the security policy.

In addition to configuring traffic prioritization, you may also choose to limit bandwidth that's received by each interface. This can sometimes be useful in scenarios where you want to limit traffic levels, but don't want to configure traffic shaping within a security policy. This has the benefit of policing traffic at a point before the FortiGate performs most processing.

Note that if you implement QoS using ToS octet rather than security policies, the FortiGate applies QoS on a packet-by-packet basis, and priorities may be different for packets and services controlled by the same security policy. This is more granular control than prioritization by security policies, but has the drawbacks that quality of service may not be uniform for multiple services controlled by the same security policy, packets only use up to three of the six possible queues (queue 0 to queue 2), and bandwidth can't be guaranteed. Other devices in your network must also be able to set or preserve ToS bits.

In this example, we limit the bandwidth accepted by each source interface, and then configure prioritized queuing on the destination interface based upon the value of the ToS bit located in the IP header of each accepted packet.

To limit bandwidth accepted by an interface - CLI:

```
config system interface
  edit <interface_name>
    set inbandwidth <limit>
  next
end
```

where <limit> is the bandwidth limit in Kbps. Excess packets are dropped.

To configure the global priority value - CLI:

```
config system global
  set tos-based-priority {high | low | medium}
end
```

where `high` has a priority value of 0 and `low` is 2.

If you want to prioritize some ToS bit values differently than the global ToS-based priority, configure the priority for packets with that ToS bit value using the following commands:

```
config system tos-based-priority
  edit <id_int>
    set tos [0-15]
    set priority {high | low | medium}
  next
end
```

where `tos` is the value of the ToS bit in the packet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in this location will override the global ToS-based priority.

Sample configuration

This sample configuration limits ingress bandwidth to 500 Kbps. It also queues egress traffic based upon the ToS bit in the IP header of ingress packets.

Unless specified for the packet's ToS bit value, packets use the low priority queue (queue 2). For ToS bit values 4 and 15, the priorities are specified as medium (value 1) and high (value 0), respectively.

```
config system interface
  edit wan1
    set inbandwidth 500
  next
end
config system global
  set tos-based-priority low
end
config system tos-based-priority
  edit 4
    set tos 4
    set priority medium
  next
  edit 15
    set tos 15
    set priority high
  next
end
```

Example setup for VoIP

In this example, there are three traffic shaping requirements for a network:

- Voice over IP (VoIP) requires a guaranteed, high-priority for bandwidth for telephone communications.
- FTP bursts must be contained so it doesn't consume any available bandwidth. As such, this traffic needs to be throttled to a smaller amount.
- A consistent bandwidth requirement is needed for all other email and web-based traffic.

To enable this requirement, you need to create three separate traffic shapers and three traffic shaping policies for each traffic type.

In this example, the values used aren't recommended values.

Creating the traffic shapers

First create the traffic shapers that define the maximum and guaranteed bandwidth. The shared traffic shapers are used with some applied per-policy and some applied to all policies, to better control traffic.

VoIP shaper

The VoIP functionality is a key component to the business as a communication tool and as such requires a guaranteed bandwidth. This traffic shaper is a high priority traffic shaper.

To create a VoIP shaper - GUI:

1. Go to **Policy & Objects > Traffic Shapers** and select **Create New**.
2. Set the **Type** to **Shared**.
3. Enter the **Name** `voip`.
4. Set the **Traffic Priority** to **High**.
5. Select **Maximum Bandwidth** and enter `1000 Kbps`.
6. Select **Guaranteed Bandwidth** and enter `800 Kbps`.
7. Select **OK**.
8. Select the HTTP shaper, right-click it, and select **Edit in CLI**. Type the following command:

```
set per-policy
end
```

To create a VoIP shaper - CLI:

```
config firewall shaper traffic-shaper
edit voip
    set maximum-bandwidth 1000
    set guaranteed-bandwidth 800
    set per-policy enable
    set priority high
end
```

Setting the traffic shaper to **per-policy** ensures that regardless of the number of policies that use this traffic shaper, the defined bandwidth is always the same. At the same time, the bandwidth is continually guaranteed at 800 Kbps but, if available, can be as much as 1000 Kbps. Setting the priority to high ensures that the FortiGate considers VoIP traffic the most important.

FTP traffic shaper

The FTP traffic shaper sets the maximum bandwidth to use to avoid sudden spikes by sudden uploading or downloading of large files, and interfering with other more important traffic.

To create a FTP shaper - GUI:

1. Go to **Policy & Objects > Traffic Shapers** and **Create New**.
2. Set the **Type** to **Shared**.
3. Enter the **Name** `ftp`.
4. Set the **Traffic Priority** to **Low**.
5. Select **Maximum Bandwidth** and enter `200 Kbps`.
6. Select **Guaranteed Bandwidth** and enter `200 Kbps`.
7. Select **OK**.

To create a FTP shaper - CLI:

```
config firewall shaper traffic-shaper
edit ftp
    set maximum-bandwidth 200
```

```
set guaranteed-bandwidth 200
set priority low
end
```

For this traffic shaper, the maximum and guaranteed bandwidth are set to a low value and to the same value. In this case, the bandwidth is restricted to a specific amount. Setting the traffic priority to a low value ensures that more important traffic passes before FTP traffic.

Regular traffic shaper

The regular traffic shaper sets the maximum bandwidth and guaranteed bandwidth for everyday business traffic such as web and email traffic.

To create a regular traffic shaper - GUI:

1. Go to **Policy & Objects > Traffic Shapers** and **Create New**.
2. Set the **Type** to **Shared**.
3. Enter the **Name** `daily_traffic..`
4. Set the **Traffic Priority** to **Medium**.
5. Select **Maximum Bandwidth** and enter `600 Kbps`
6. Select **Guaranteed Bandwidth** and enter `600 Kbps`.
7. Select **OK**.

To create a regular traffic shaper - CLI:

```
config firewall shaper traffic-shaper
edit daily_traffic
set maximum-bandwidth 600
set guaranteed-bandwidth 600
set per-policy enable
set priority medium
end
```

For this traffic shaper, the maximum and guaranteed bandwidth are set to a moderate value of 600 Kbps. It's also set per policy, which ensures each security policy for day-to-day business traffic has the same distribution of bandwidth.

Creating traffic shaping policies

To employ the traffic shapers, create traffic shaping policies that apply to your existing security policy. Create a separate policy for each service and apply the traffic shaper to the outgoing interface you want to use. For example, a policy for FTP traffic, a policy for SIP, and so on.

For the following steps, the VoIP traffic shaper is enabled as well as the reverse direction. This ensures that return traffic for a VoIP call has the same guaranteed bandwidth as the outgoing call. The example below shows how to enable each traffic shaper in a traffic shaping policy.

In this example, the traffic shaping policies will apply traffic shaping to the following security policy:

Incoming interface	lan (Internal interface)
---------------------------	--------------------------

Source address	All
Outgoing interface	WAN1
Destination address	All
Schedule	always
Service	all
Action	ACCEPT

To create a VOIP traffic shaping policy- GUI:

1. Go to **Policy & Objects > Traffic Shaping Policy** and select **Create New**.
2. Now create a traffic shaping policy that matches the settings you entered for the security policy:

Source	All
Destination	All
Service	All
Application Category	VoIP
Application	SIP
URL Category	Internet Telephony
Outgoing Interface	wan1

3. Enable **Shared Shaper**, select the VoIP traffic shaper that you created in the previous steps.
4. Enable **Reverse Shaper**, select the VoIP traffic shaper that you created in the previous steps.
5. Select **Enable this policy**.
6. Select **OK**.

To create a VOIP traffic shaping policy - CLI:

```
config firewall shaping-policy
edit 1 <shaping_policy_ID_number>
set srcaddr all
set dstaddr all
set service ALL
set application 34640 <SIP>
set app-category 3 <VoIP>
set url-category 76 <Internet Telephony>
set dstintf wan1 <outgoing_interface>
set traffic-shaper voip <high_priority_custom_shaper>
set reverse-traffic-shaper voip <high_priority_custom_shaper>
end
```

To create an FTP traffic shaping policy - GUI:

1. Go to **Policy & Objects > Traffic Shaping Policy** and select **Create New**.
2. Now create a traffic shaping policy that matches the settings you entered for your security policy:

Source	All
Destination	All
Service	FTP
Outgoing Interface	wan1

3. Enable **Shared Shaper**, select the FTP shaper created in the previous steps.
4. Enable **Reverse Shaper**, select the FTP shaper created in the previous steps.
5. Select **Enable this policy**.
6. Select **OK**.

To create an FTP traffic shaping policy - CLI:

```
config firewall shaping-policy
edit 2 <shaping_policy_ID_number>
set srcaddr all
set dstaddr all
set service FTP
set dstintf wan1 <outgoing_interface>
set traffic-shaper FTP <low_priority_custom_shaper>
set reverse-traffic-shaper FTP <low_priority_custom_shaper>
end
```

To create a regular traffic shaping policy - GUI:

1. Go to **Policy & Objects > Traffic Shaping Policy** and select **Create New**.
2. Now create a traffic shaping policy that matches the settings you entered for your security policy:

Source	All
Destination	All
Service	ALL
Outgoing Interface	wan1

3. Enable **Shared Shaper**, select the medium-priority shaper.
4. Enable **Reverse Shaper**, select the medium-priority shaper.
5. Select **Enable this policy**.
6. Select **OK**.

To create a regular traffic shaping policy - CLI:

```
config firewall shaping-policy
```

```
edit 3 <shaping_policy_ID_number>
  set srcaddr all
  set dstaddr all
  set service ALL
  set dstintf wan1 <outgoing_interface>
  set traffic-shaper medium-priority <default_shaper>
  set reverse-traffic-shaper medium-priority <default_shaper>
end
```

To order your traffic shaping policies - CLI:

```
config firewall shaping-policy
  move 1 before 2
  move 3 below 2
end
```

Ensure that your high priority SIP/VoIP policy is at the top of the policy list, the low priority FTP traffic shaper comes second, and the medium priority regular traffic shaper comes last. Restrictive policies should always go above more general access policies.

Alternate method of enabling traffic shaping in the security policy

It's also possible to create three separate security policies for each type of traffic (VoIP, FTP, and regular). You can enable traffic shaping individually within each security policy in the CLI only, like the example shown below:

To enable traffic shaping in the security policy - CLI:

```
config firewall policy
  edit 6
    set srcintf <internal_interface>
    set scraddr all
    set dstintf wan1
    set dstaddr all
    set action accept
    set schedule always
    set service sip
    set traffic-shaper voip
    set reverse-traffic-shaper voip
  end
```

Troubleshooting traffic shaping

This chapter outlines some troubleshooting tips and steps to diagnose the traffic shapers and whether they're working correctly. These diagnose commands include:

- `diagnose system tos-based-priority`
- `diagnose firewall shaper traffic-shaper`
- `diagnose firewall per-ip-shaper`
- `diagnose debug flow`

Interface diagnosis

To optimize traffic shaping performance, first ensure that the network interface's Ethernet statistics are clean of errors, collisions, or buffer overruns. To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

Traffic shaper diagnose commands

There are specific diagnose commands you can use to verify the configuration and flow of traffic, including packet loss due to the employed traffic shaper.

All of these diagnose troubleshooting commands are supported in both IPv4 and IPv6.

ToS command

Use the following command to list command to view information of the ToS lists and traffic:

```
diagnose system tos-based-priority
```

This example displays the priority value currently correlated with each possible ToS bit value. Priority values are displayed in order of their corresponding ToS bit values, which can range between 0 and 15, from lowest ToS bit value to highest.

For example, if you configured ToS-based priorities, the following appears:

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
```

This reflects that all packets are currently using the same default priority, high (value 0).

If you configured a ToS-based priority of `low` (value 2) for packets with a ToS bit value of 3, the following appears:

```
0 0 0 2 0 0 0 0 0 0 0 0 0 0 0 0
```

This reflects that most packets are using the default priority value, except those with a ToS bit value of 3.

Shared traffic shaper

To view information for the shared traffic shaper for security policies, enter the command:

```
diagnose firewall shaper traffic-shaper list
```

The resulting output displays the information on all available traffic shapers. The more traffic shapers that are available, the longer the list. For example:

```
name Throughput
maximum-bandwidth 1200000 Kb/sec
guaranteed-bandwidth 50000 Kb/sec
current-bandwidth 0 B/sec
priority 1
packets dropped 0
```

Additional commands include:

`diagnose firewall shaper traffic-shaper state` - provides the total number of traffic shapers on the FortiGate.

`diagnose firewall shaper traffic-shaper stats` - provides summary statistics on the shapers.

Sample output looks like the following:

```
shapers 9 ipv4 0 ipv6 0 drops 0
```

Per-IP traffic shaper

To view information for the per-IP traffic shaper for security policies, enter the command:

```
diagnose firewall shaper per-ip-shaper list
```

The resulting output displays the information on all available per-IP traffic shapers. The more traffic shapers that are available, the longer the list. For example:

```
name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 0
```

Additional commands include:

`diagnose firewall shaper per-ip-shaper state` - provides the total number of per-ip traffic shapers on the FortiGate.

`diagnose firewall shaper per-ip-shaper stats` - provides summary statistics on the traffic shapers. Sample output looks like the following:

```
memory allocated 3 packet dropped: 0
```

You can also clear the per-ip statistical data to begin a fresh diagnosis using:

```
diagnose firewall shaper per-ip-shaper clear
```

Packet loss with statistics on traffic shapers

For each traffic shaper there are counters that allow you to verify if packets have been discarded. To view this information, enter the `diagnose firewall shaper` command in the CLI. The results look similar to the following output:

```
diagnose firewall shaper traffic-shaper list
name limit_GB_25_MB_50_LQ
maximum-bandwidth 50 Kb/sec
guaranteed-bandwidth 25 Kb/sec
current-bandwidth 51 Kb/sec
priority 3
dropped 1291985
```

The diagnose command output is different if the diagnose firewall shapershapers are configured either per-policy or shared between policies.

For per-IP the output is:

```
diagnose firewall shaper per-ip-shaper list

name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 3264220
```

Packet lost with the debug flow

When using the debug flow diagnostic command, there is a specific message information that a packet has exceed the diagnose firewall shapershaper limits and therefore discarded:

```
diagnose debug flow show console enable
diagnose debug flow filter addr 10.143.0.5
diagnose debug flow trace start 1000

id=20085 trace_id=11 msg="vd-root received a packet(proto=17, 10.141.0.11:3735-
>10.143.0.5:5001) from port5."
id=20085 trace_id=11 msg="Find an existing session, id=0000eabc, original direction"
id=20085 trace_id=11 msg="exceeded shaper limit, drop"
```

Session list details with dual traffic shaper

When a security policy has a different traffic shaper for each direction, it's reflected in the session list output from the CLI:

```
diagnose system session list

session info: proto=6 proto_state=02 expire=115 timeout=3600 flags=00000000 sock
flag=00000000 sockport=0 av_idx=0 use=4
origin-shaper=Limit_25Mbps prio=1 guarantee 25600/sec max 204800/sec traffic 48/sec
reply-shaper=Limit_100Mbps prio=1 guarantee 102400/sec max 204800/sec traffic 0/sec
ha_id=0 hakey=44020
policy_dir=0 tunnel=/
state=may_dirty rem os rs
statistic(bits/packets/allow_err): org=96/2/1 reply=0/0/0 tuples=2
orgin->sink: org pre->post, reply pre->post dev=2->3/3->2 gwy=10.160.0.1/0.0.0.0
hook=pre dir=org act=dnat 192.168.171.243:2538->192.168.182.110:80(10.160.0.1:80)
hook=post dir=reply act=snat 10.160.0.1:80->192.168.171.243:2538(192.168.182.110:80)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0 serial=00011e81 tos=ff/ff app=0
dd_type=0 dd_rule_id=0
```

Additional information

- Packets discarded by the traffic shaper impact flow-control mechanisms like TCP. For more accurate testing results, use the UDP protocol.
- Traffic shaping accuracy is optimum for security policies without a protection profile where no FortiGate content inspection is processed.

- Don't oversubscribe an outbandwidth throughput. For example, $\text{sum}[\text{guaranteed BW}] < \text{outbandwidth}$. For accuracy in bandwidth calculation, it's required to set the "outbandwidth" parameter on the interfaces. For more information, see ["Bandwidth guarantee, limit, and priority interactions" on page 2784](#).
- The FortiGate isn't prioritizing traffic based on the DSCP marking configured in the security policy. However, ToS-based prioritizing can be made at ingress. For more information, see ["Traffic shaping methods" on page 2791](#).

Chapter 26 - Transparent Mode

- [Transparent mode overview](#): an overview of transparent mode, including available features.

- [Best practices](#): the best practices for using transparent mode.

What's new in FortiOS 6.0

The following list contains new transparent mode features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["Source prefixes" on page 2841](#)

Transparent mode overview

This section contains an overview of transparent mode. It contains the following topics:

- [What is transparent mode?](#)
- [Transparent mode features](#)

What is transparent mode?

A FortiGate can operate in one of two modes: transparent or NAT/route mode.

In transparent mode, the FortiGate is installed between the internal network and the router. In this mode, the FortiGate does not make any changes to IP addresses and only applies security scanning to traffic. When a FortiGate is added to a network in transparent mode, no network changes are required, except to provide the FortiGate with a management IP address. transparent mode is used primarily when there is a need to increase network protection but changing the configuration of the network itself is impractical.

In NAT/route mode, a FortiGate is installed as a gateway or router between two networks. This allows the FortiGate to hide the IP addresses of the private network using network address translation (NAT).

Transparent mode features

Different FortiOS features are available depending on whether your FortiGate is in transparent or NAT/route mode. The following table shows which features are available for each mode.

For a FortiGate in transparent mode, the maximum number of Interfaces per VDOM is 254. This value includes both physical and virtual interfaces.

For any other maximum values, please consult the Maximum Values Table, available at docs.fortinet.com.

Feature	NAT	Transparent	Comment
Unicast routing/policy-based routing	Yes	No	
VIP/IP pools/ NAT	Yes	Yes	Configurable from CLI only in transparent mode
Multicast routing	Yes	No	Options are available to forward multicast packets
L2 forwarding	No	Yes	In transparent mode, other frames than IP can be forwarded, but only without security scanning

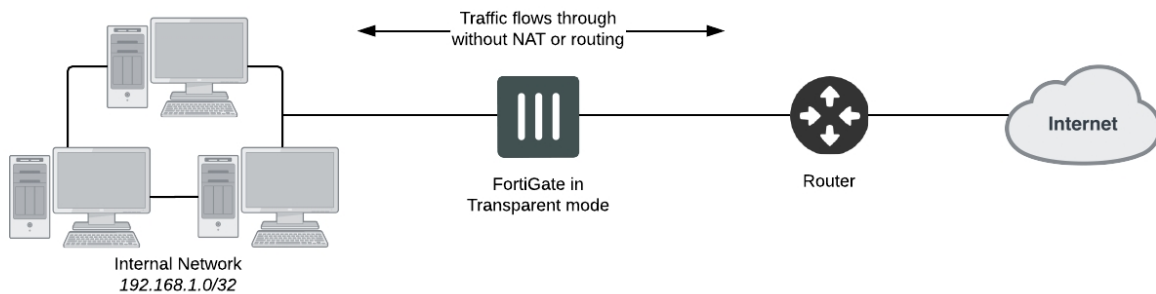

Feature	NAT	Transparent	Comment
Firewall (packet filtering/NAT/Authentication)	Yes	Yes	
IPv6 capable	Yes	Yes	
Traffic shaping (type of service)	Yes	Yes	
Hardware acceleration	Yes	Yes	
All security profile features (ex IPS, Application Control, Web Filtering, etc ...)	Yes	Yes	
Security Fabric	Yes	No	
FortiView	Yes	Yes	
IPsec VPN	Yes	Yes	Only policy based IPsec VPNs are supported for transparent mode
SSL VPN	Yes	No	
High availability (HA) - virtual cluster	Yes	Yes	
802.3ad (LACP/port aggregation)	Yes	Yes	
HA port redundancy	Yes	Yes	FortiGate hardware dependent
802.1q - VLAN trunking	Yes	Yes	
802.1d - spanning tree	No	No	Option to forward VPDUs
Logging and reporting (disk and memory logging, FortiCloud, syslog, and FortiAnalyzer)	Yes	Yes	
Managed by FortiManager	Yes	Yes	

Installation

This section contains information about installing a FortiGate in transparent mode. It contains the following topics:

- [Installing a FortiGate in transparent mode](#)
- [Using a virtual wire pair to simplify transparent mode](#)
- [Management IP configuration](#)

Installing a FortiGate in transparent mode

Changing to transparent mode removes most configuration changes made in NAT/route mode. To keep your current NAT/route mode configuration, backup the configuration using the **System Information** widget, found in the **Dashboard**.

1. Before connecting the FortiGate to your network, go to the **Dashboard** and locate enter the following command into the **CLI Console**:

```
config system settings
  set opmode transparent
  set manageip <address and netmask>
  set gateway <address>
end
```

2. Access the web-based manager by browsing to the new management IP.
3. (Optional) The FortiGate's DNS Settings are set to use FortiGuard DNS servers by default, which is sufficient for most networks. However, if you need to change the DNS servers, go to **Network > DNS** and add **Primary** and **Secondary** DNS servers. Select **Apply**.
4. If your network uses IPv4 addresses, go to **Policy & Objects > IPv4 Policy** and select **Create New** to add a security policy that allows users on the private network to access the Internet.

If your network uses IPv6 addresses, go to **Policy & Objects > IPv6 Policy** and select **Create New** to add a

security policy that allows users on the private network to access the Internet. If the IPv6 menu option is not available, go to **System > Feature Visibility**, turn on **IPv6**, and select **Apply**. For more information on IPv6 networks, see the IPv6 Handbook.

Set the **Incoming Interface** to the internal interface and the **Outgoing Interface** to the Internet-facing interface (typically WAN1). You will also need to set **Source Address**, **Destination Address**, **Schedule**, and **Service** according to your network requirements. You can set these fields to the default all/ANY settings for now but should create the appropriate objects later after the policies have been verified.

5. Make sure the **Action** is set to **ACCEPT**. Select **OK**.

It is recommended to avoid using any security profiles, such as AntiVirus or web filtering, until after you have successfully installed the FortiGate. After the installation is verified, you can apply any required security profiles.

For more information about using security profiles, see the Security Profiles handbook.

6. Go to the **Dashboard** and locate the **System Resources** widget. Select **Shutdown** to power off the FortiGate. Alternatively, you can also use the CLI command `execute shutdown`.
7. Connect the FortiGate between the internal network and the router.
8. Connect the Internet-facing interface to the router's internal interface and connect the internal network to the FortiGate using an internal port (typically port 1).
9. Power on the FortiGate. You will experience downtime before the FortiGate starts up completely.

Results

Users on the internal network are now able to browse to the Internet. They should also be able to connect to the Internet using any other protocol or connection method that you defined in the security policy.

If a FortiGate operating in transparent mode is installed between your internet network and a server that is providing a network service to the internal network, such as DNS or DHCP, you must add a wan1-to-internal policy to allow the server's response to flow through the FortiGate and reach the internal network.

Using a virtual wire pair to simplify transparent mode

A virtual wire pair consists of two interfaces that have no IP addresses and all traffic received by one interface in the pair can only be forwarded out the other; as controlled by firewall policies. Since the interfaces do not have IP addresses, you can insert a virtual wire pair into a network without having to make any changes to the network.

Interfaces used in a virtual wire pair cannot be used for admin access to the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

1. Go to **Network > Interfaces** and select **Create New > Virtual Wire Pair**. Add two ports to the virtual wire pair. These ports cannot be part of a switch, such as the default **internal/lan** interface.
2. Go to **Policy & Objects > IPv4 Virtual Wire Pair Policy** and create a policy will allow traffic to flow between the two ports. Give the policy an appropriate **Name**. Select the direction that traffic is allowed to flow. Configure the other firewall options as needed.
3. If necessary, create a second virtual wire pair policy allowing traffic to flow between the ports in the opposite direction.

Traffic can now flow between the two ports. Go to **FortiView > All Segments > Policies** to see traffic flowing through both policies.

Management IP configuration

A FortiGate in transparent mode can be assigned with a single IP address for remote access management and multiple static routes can be configured. This can be used if in-band management wants to be applied.

When out-of-band management is desired (dedicated interface for remote management access), it is recommended to use a separate VDOM in NAT/route mode.

In-band management details and example

The management IP address is bound to all ports or VLANs belonging to the same VDOM. Remote access services are subject to the same rules as in NAT/route mode, and must be enabled/disabled on each port.

Example of management IP configuration in transparent mode:

```
config system settings
  set manageip 10.1.1.100/255.255.255.0
end
config router static
  edit 1
    set gateway 10.1.1.254
  next
end
config system interface
  edit port1
    set allowaccess ping ssh https snmp
  end
```

It is also possible to add a second IP address for management and additional default routes:

```
config system settings
  set opmode transparent
  set manageip 192.168.182.136/255.255.254.0 10.1.1.1/255.255.255.0
```

```
end

config router static
  edit 1
    set gateway 192.168.183.254
  next
  edit 2
    set gateway 10.1.1.254
  next
end
```

`ping-server` (dead gateway detection) is not supported in transparent mode.

Out-of-band management details and example

When VDOM is enabled and the VDOMs are operating in transparent mode, it is recommended, to avoid L2 loops and allow more routing flexibility, to keep one VDOM (generally the root VDOM) in NAT/route mode, with one or more VLAN or physical interface as out-of-band management.

The management VDOM must have IP connectivity to the Internet to allow communication with the FDS and retrieve services information (antivirus, IPS, FortiGuard, FortiCare, etc...). All syslog and FortiManager communication also go through the management VDOM.

Networking in transparent mode

This section contains information about networking concepts in transparent mode. It contains the following topics:

- [Static routing](#)
- [Packet forwarding](#)
- [Network address translation \(NAT\)](#)
- [VLANs and forwarding domains](#)
- [Inter-VDOM links between NAT/route and transparent VDOMs](#)
- [Packet forwarding using Cisco protocols](#)
- [Configuration example](#)

Static routing

The following sections include information about configuring static routing in transparent mode:

- [Overview](#)
- [Source prefixes](#)

Overview

When you configure routing in transparent mode on a FortiGate, all interfaces must be connected to the same subnet. This means all traffic comes from and leaves on the same subnet. This is important because it limits the static routing options to only gateways that are attached to this subnet. For example, if you have only one router that connects your network to the Internet, all static routing on the FortiGate uses this gateway. For this reason, static routing on a FortiGate in transparent mode may be a bit different, but it's not as complex as routing in NAT mode.

To view the routing table in transparent mode, go to **Network > Static Routes**. When you view entries for static routes in transparent mode, you'll see the following settings:

Field	Description
Destination	When Subnet is selected, shows the IP address and netmask of the destination of the traffic being routed. 0.0.0.0 is the default route and matches all traffic destinations.
Gateway	Specifies the IP address of the next hop for traffic. This is usually the IP address of a router on the edge of your network.

Field	Description
Priority	<p>The FortiGate uses the priority if there's more than one match for a route. This allows you to use multiple routes, but configure preferred routes.</p> <p>Routes with a larger value have a lower priority. If the preferred route isn't available, another route is used instead. If there is more than one match for a route, and the routes have the same priority, the FortiGate uses Equal Cost Multiple Path (ECMP) to share traffic between the routes.</p> <p>The possible values are 0 to 4294967295. This setting only applies to static routes. The priority for routes that are dynamically learned from routing protocols is 0.</p>

Source prefixes

If a FortiGate has more than one management IP address and default route, packets can't differentiate between them and may reach the wrong management IP address. To avoid this, you can configure a source prefix that allows the FortiGate to differentiate between multiple default routes.

To configure source prefixes - CLI

```
config router static
  edit <sequence number>
    set gateway <IP address>
    set src <source prefix>
  next
  edit <sequence number>
    set gateway <IP address>
    set src <source prefix>
  next
end
```

Packet forwarding

The following sections include information about configuring packet forwarding in transparent mode:

- [MAC learning and L2 forwarding table](#)
- [Broadcast, multicast, and unicast forwarding](#)
- [Multicast processing](#)
- [Source MAC addresses](#)
- [ARP table](#)
- [Verifying the forwarding database](#)
- [STP forwarding](#)
- [Non-IPv4 Ethernet frames forwarding](#)

MAC learning and L2 forwarding table

When operating in transparent mode, a FortiGate behaves like an L2 switch in accordance with 802.1d principles:

- The forwarding database (FDB) is populated with the network devices MAC addresses during a MAC learning process, based on the source addresses seen in the Ethernet frames ingressing a FortiGate port. Static MAC

entries can also be configured using the following CLI command:

```
config system mac-address-table
edit 00:01:02:03:04:05
set interface "port3"
next
end
```

The FDB table can be verified with the following command: `diagnose netlink brctl name host TP.b`

- Ethernet IP frames forwarding is based on known MAC address on each port.
- As Spanning Tree is not running on the FortiGate, a port that comes up goes immediately into forwarding or flooding state. This last state will not occur once unicast MAC addresses are present in the FDB.

If the FortiGate in transparent mode bridges traffic to a router or host using a virtual MAC for one direction and a different physical MAC for the other direction (for example, when VRRP or HSRP protocols are used), it is highly recommended to create a static MAC entry for the virtual MAC. This is to make sure that the virtual MAC address is present in the FDB.

Broadcast, multicast, and unicast forwarding

In transparent mode, IPv4 packets are typically only forwarded by the FortiGate from a port to another port when a firewall policy is matched with action ACCEPT.

Below are exceptions.

- **L2 (IP) Broadcast frames forwarding:**

L2 (IP) means a L2 frame type 0x0800 (IP) or 0x0806 (ARP)

- **ARP:** by default, ARP broadcasts and ARP reply packets are flooded/forwarded on all ports or VLANs belonging to the same forwarding domain, without the need of firewall policies between the ports. This default behavior is necessary to allow the population of the FDB and allow further firewall policy lookup (see section transparent mode Firewall processing for more details). This option is configurable at the interface settings level with the parameter `arpforward` (enabled by default).
- **Non-ARP:** To forward non-ARP broadcasts, the following CLI command is used:

```
config system interface
edit "port2"
set broadcast-forward enable
next
end
```

- **L2 (IP) Multicast frames forwarding:** the FortiGate does not forward frames with multicast destination MAC addresses by default. Multicast traffic such as one used by routing protocols or streaming media may need to traverse the FortiGate which should not interfere this communication.

Fortinet recommends that the FortiGate is set up using Multicast policies. This allows for greater control and

predictability on traffic behavior. However Multicast traffic may be forwarded through a transparent mode device using the `multicast-skip-policy` setting. This is detailed in the section ["Multicast processing" on page 2843](#)

- **L2 (IP) Unicast frames forwarding:** a frame with a unicast destination MAC address is subject to firewall processing before being forwarded (see ["Firewall policy look up" on page 2856](#) for more details). This does not apply to ARP replies.

Multicast processing

In transparent mode, a FortiGate does not forward frames with multicast destination MAC addresses by default. If multicast traffic is required, multicast policies are recommended to allow finer control of this traffic.

Forwarding all multicast traffic with policy

Multicast traffic may have to be forwarded through a transparent mode device using the `multicast-skip-policy` system setting. This is the configuration for this solution:

```
config system settings
    set multicast-skip-policy enable
end
```

In that case, no check is performed on sources/destinations/interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces (except the incoming interface) belonging to the same forwarding domain.

Configuring firewall multicast-policy

The use of `firewall multicast-policy` allows a finer control over the multicast packets. Hereafter are some commented examples. Note that the parameter `multicast-skip-policy` mentioned above must be left to disabled.

Those policies can only be configured from the CLI.

1. Simple policy

```
config firewall multicast-policy
    edit 1
        set action accept
    next
end
```

In that case, no check is performed on sources/destinations/interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces (except the incoming interface) belonging to the same forwarding domain.

2. To restrict incoming and outgoing interfaces:

```
config firewall multicast-policy
    edit 1
        set srcintf "port1"
        set dstintf "port2"
        set action accept
    next
end
```

3. To be more restrictive (example to allow RIP2 packets from port1 to port2 and sourced by 10.10.0.10):

```
config firewall multicast-policy
edit 1
set srcintf "port1"
set srcaddr 10.10.0.10 255.255.255.255
set dstintf "port2"
set dstaddr 224.0.0.9 255.255.255.255
set action accept
next
end
```

4. This policy will allow all 224.0.0.0/255 range (OSPF, RIPv2, DVMRP...) from port1 to port2

```
config firewall multicast-policy
edit 1
set srcintf "port1"
set dstintf "port2"
set dstaddr 224.0.0.0 255.255.255
set action accept
next
end
```

Source MAC addresses

When a FortiGate is in transparent mode, it does not typically alter the original source and destination address of packets that flow through the unit. Because of this, end devices do not “see” the MAC address of the FortiGate. However, if network address translation (NAT) is enabled by a firewall policy, the source MAC address will be the MAC address of the FortiGate's management interface.

IP packets that are initiated by the FortiGate (remote management, access to FortiGuard server...) are sent in L2 Ethernet frames that have a source MAC address of the interface in the virtual domain (VDM) with the lowest MAC address. Below is an example with port2 and port3 in the same VDM, remote access done via port3, but the sniffer trace showing MAC address of port2. The address of port2 is shown in bold.

```
diagnose hardware deviceinfo nic port2
[...]
Current_HWaddr      00:09:0F:85:3F:C4
Permanent_HWaddr    00:09:0F:85:3F:C4

fgt300 (global) # diagnose hardware deviceinfo nic port3
[...]
Current_HWaddr      00:09:0F:85:3F:C5

```

ARP table

In transparent mode, the Address Resolution Protocol (ARP) table is used in the following situations:

- For IP traffic received or originated by the FortiGate itself, and in destination of the management device or next-hop.
- When IPsec is used, the FortiGate uses its ARP table to forward the traffic from the IPsec tunnel to the local destination host(s).

All other forwarding decision is based on the Forwarding Database (FDB) table or optional settings.

Verifying the forwarding database

To view all instances of the forwarding database (FDB), use the following CLI command:

```
diagnose netlink brctl list
```

Example

```
FGT # diagnose netlink brctl list

list bridge information
1. root.b      fdb: size=256    used=6    num=7    depth=2    simple=no
2. mgmt.b      fdb: size=256    used=5    num=4    depth=2    simple=no
Total 2 bridges
```

Here above we can see two bridge instances for 2 VDOMs in transparent mode: `root` and `mgmt`.

- This command will dump the L2 forwarding table for each VDOM bridge instance:

```
diagnose netlink brctl name host <VDOM_name>.b
```

Example for the root VDOM:

```
FGT# diag netlink brctl name host root.b

show bridge control interface root.b host.
fdb: size=256, used=6, num=7, depth=2, simple=no
Bridge root.b host table
```

port	no	device	devname	mac addr	tvl	atributes

STP forwarding

By default, the FortiGate does not forward Spanning Tree Protocol (STP) bridge protocol data units (BPDUs). If you require STP forwarding, in most configurations you must enable STP forwarding on the interface. If your FortiGate is in one-armed sniffer mode, you must instead enable STP forwarding mode on the interface.

Layer 2 loops may occur if STP is broken due to the FortiGate blocking STP BPDUs.

STP forwarding on the interface

To enable STP forwarding on an interface, use the following CLI command:

```
config system interface
  edit <interface_name>
    set stpforward enable
  next
end
```

STP forwarding mode

STP forwarding mode is an additional option that you use for STP handling when your FortiGate in one-armed sniffer mode. To configure STP forwarding mode, use the following CLI command:

```
config system interface
  edit <interface_name>
    set stpforward-mode {rpl-all-ext-id | rpl-bridge-ext-id | rpl-nothing}
  next
end
```

Non-IPv4 Ethernet frames forwarding

In the situation where non IP frames (or non Ethernet II) frames need to be accepted on a port, the parameter `l2forward` can be enabled (disabled by default). This can be used to forward frames such as PPPoE PADI, Appletalk, on other ports belonging to the same forwarding domain.

The procedure is the following:

```
config system interface
  edit port1
    set l2forward enable
  next
  edit port2
    set l2forward enable
  next
end
```

Network address translation (NAT)

While NAT is generally not used by a FortiGate in transparent mode, both [source network address translation \(SNAT\)](#) and [destination network address translation \(DNAT\)](#) can be configured.

Configuring SNAT

Source Network Address Translation (SNAT) is an option available in transparent mode and configurable in CLI only, using the following commands:

```
config firewall ippool
```

```
edit "nat-out"
    set endip 192.168.183.48
    set startip 192.168.183.48
    set interface vlan18_p3
next
end

config firewall policy
    edit 3
        set srcintf "vlan160_p2"
        set dstintf "vlan18_p3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set ippool enable
        set poolname "nat-out"
        set schedule "always"
        set service "ANY"
        set nat enable
    next
end
```

The sniffer trace below shows the source IP 192.168.182.93 being source translated to 192.168.183.48:

```
fgt300 (TP) # diagnose sniffer packet any "host 10.2.2.1" 4

interfaces=[any]
filters=[host 10.2.2.1]
4.891970 vlan160_p2 in 192.168.182.93 -> 10.2.2.1: icmp: echo request
4.892003 vlan18_p3 out 192.168.183.48 -> 10.2.2.1: icmp: echo request
4.892007 port3 out 192.168.183.48 -> 10.2.2.1: icmp: echo request
4.933216 vlan18_p3 in 10.2.2.1 -> 192.168.183.48: icmp: echo reply
4.933249 vlan160_p2 out 10.2.2.1 -> 192.168.182.93: icmp: echo reply
4.933253 port2 out 10.2.2.1 -> 192.168.182.93: icmp: echo reply
```

Configuring DNAT

The following example shows how to configure Destination Network Address Translation (DNAT) using a virtual IP on a FortiGate in Transparent Mode:

```
config firewall vip
    edit "vip1"
        set extip 192.168.183.48
        set extintf "vlan160_p2"
        set mappedip 192.168.182.78
    next
end

config firewall policy
    edit 4
        set srcintf "vlan160_p2"
        set dstintf "vlan18_p3"
        set srcaddr "all"
        set dstaddr "vip1"
        set action accept
        set schedule "always"
        set service "ANY"
    next
```

end

If the `mappedip` is on a different subnet than the management IP, the FortiGate must have a valid route to this destination

The sniffer trace below shows the destination IP 192.168.183.48 being translated to 192.168.182.78:

```
fgt300 (TP) # diagnose sniffer packet any "icmp" 4

interfaces=[any]
filters=[icmp]
4.126138 vlan160_p2 in 192.168.182.93 -> 192.168.183.48: icmp: echo request
4.126190 vlan18_p3 out 192.168.182.93 -> 192.168.182.78: icmp: echo request
4.126196 port3 out 192.168.182.93 -> 192.168.182.78: icmp: echo request
4.126628 vlan18_p3 in 192.168.182.78 -> 192.168.182.93: icmp: echo reply
4.126661 vlan160_p2 out 192.168.183.48 -> 192.168.182.93: icmp: echo reply
4.126667 port2 out 192.168.183.48 -> 192.168.182.93: icmp: echo reply
```

VLANs and forwarding domains

The following sections include information about configuring virtual local area networks (VLANs) and forwarding domains in transparent mode:

- [VLANs in transparent mode](#)
- [Forwarding domains in transparent mode](#)
- [VLANs vs forwarding domains](#)
- [VLAN forwarding](#)
- [Unknown VLANs and VLAN forwarding](#)
- [VLAN trunking and MAC address learning](#)
- [VLAN translation](#)

VLANs in transparent mode

A VLAN configured on a physical port is used to classify a packet in a broadcast domain in ingress and to tag packet in egress. A VLAN on the FortiGate conforms to the standard 802.1q. The following rules apply to VLAN configuration:

- a VLAN ID can be used only once on the same physical port
- the same VLAN ID can be used on a different port
- the VLAN ID range is from 1 to 4094

Forwarding domains in transparent mode

A forwarding domain is used to create separate broadcast domains and confine traffic across two or more ports. It also allows learning the same MAC in different VLANs (IVL).

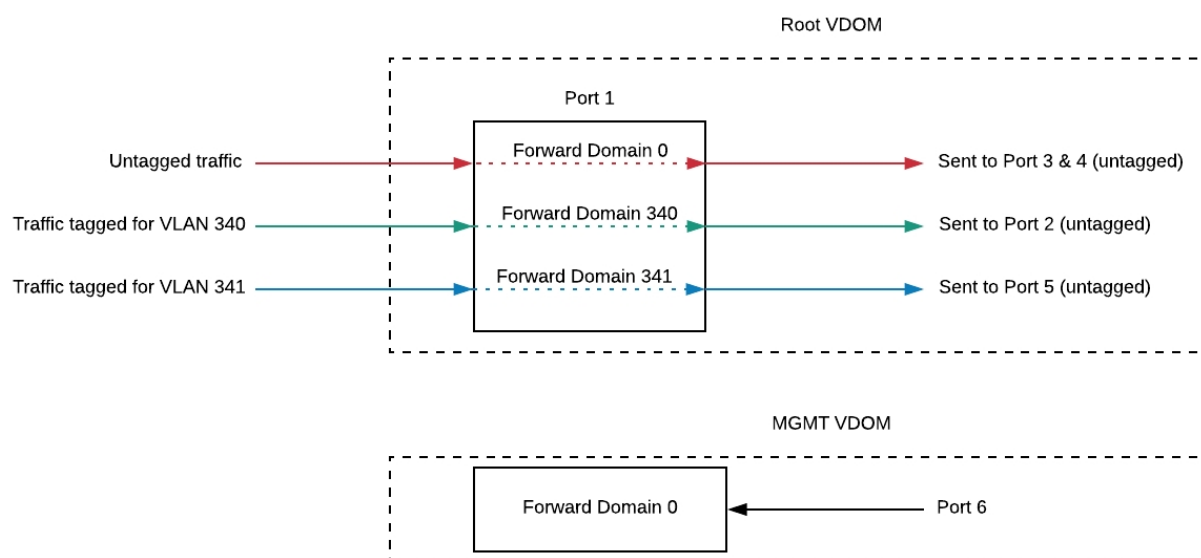

A forwarding domain and its associated ID number are unique across one VDOM, or a FortiGate with VDOMs disabled. Each new VDOM will create a new bridge instance in the FortiGate.

Even though the forwarding domain ID is not in relation with the actual VLAN numbers, it is recommended, for maintenance and troubleshooting purposes, to configure one forwarding domain per VLAN and use the same forwarding domain ID as the VLANs ID.

Once forwarding domains are configured, it is possible to configure firewall policies only between ports or VLAN belonging to the same forwarding domain.

Example configuration

This example has three forwarding domains and VLANs configured. In this example, there are two VDOMs in transparent Mode: root and MGMT. Forwarding domain 0 is the default on the FortiGate or VDOM in transparent Mode.

- Root VDOM has:
 - 3 forwarding domains, 0, 340, and 341.
 - VLAN 340 configured on port1; packets will be tagged with ID 340
 - VLAN 341 configured on port1; packets will be tagged with ID 341
 - All other ports are untagged
- MGMT VDOM has got only the default forwarding domain 0

The expected behavior is the following:

- Packets untagged ingressing port1, port3 and port4 belong to the same broadcast domain in the root VDOM
- Packets tagged with VLAN 340 ingressing port1 and Packets untagged ingressing port2 belong to the same broadcast domain in the root VDOM
- Packets tagged with VLAN 341 ingressing port1 and Packets untagged ingressing port5 belong to the same

broadcast domain in the root VDOM

- Packets untagged ingressing port6 belong to a different broadcast domain in the MGMT VDOM

CLI syntax for forwarding domain 340

```
config system interface
  edit "VLAN340"
    set forward-domain 340
    set interface "port1"
    set vlanid 340
  next
  edit "port3"
    set forward-domain 340
  next
end
```

VLANs vs forwarding domains

There are several differences between VLAN and a forwarding domain configured on a FortiGate in transparent mode:

- A forwarding domain is used to create separated broadcast domains between VLANs and allow independent VLAN learning - IVL (MAC addresses in the FDB). This would be equivalent to creating VLANs on a regular L2 switch.

When VLANs are used in the network, configuring different forwarding domains is essential to avoid broadcast duplications. See also section Default VLAN forwarding behavior for additional information.

- VLANs configured on interfaces are only used for tagging packets egressing the port and classifying packets at ingress.
- The packets processed by the direct interface (or port) itself are always sent untagged and must be received untagged.

VLAN forwarding

VLAN forwarding allows you to forward all VLANs traffic of a trunk that was connecting two network devices and where the FortiGate has been introduced, without having to perform any further configuration.

It is recommended to configure forwarding domains for each VLAN and disable this parameter in order to avoid packet from looping into the trunk from one VLAN to another. By default, the parameter `vlanforward` is disabled on each physical interface of a FortiGate or VDOM in transparent mode.

Unknown VLANs and VLAN forwarding

When a FortiGate receives a tagged frame with an unknown VLAN ID, traffic can be handled one of two ways, depending on whether VLAN forwarding is enabled or disabled.

By default, VLAN forwarding is disabled and any frames that are tagged with an unknown VLAN ID are dropped by the FortiGate.

If you enable VLAN forwarding, frames tagged with an unknown VLAN ID are forwarded from the port that received the frames to all other ports in the same forwarding domain(s). This allows you to insert the FortiGate between two devices using trunk ports without any further configuration.

VLAN trunking and MAC address learning

A FortiGate port becomes a trunk when 2 or more VLANs are configured on this port, in the same or different forwarding domains.

When trunks are configured on a FortiGate, it is essential to create forward domains, in order to avoid packets looping back on the VLANs of the trunk. This will confine all broadcasts and multicast traffic between the interfaces belonging to a same forward domain.

In the case where a trunk port is configured with a VLAN in a different forwarding domains, the MAC address of the network device connected to this port learns the FDB of each forwarding domain. This is Independent VLAN Learning (IVL).

VLAN translation

The same forwarding domain can include several different VLANs. Therefore, a frame ingressing an interface with a certain VLAN ID can be forwarded to another port with another VLAN ID. This is sometimes referred as VLAN translation.

Inter-VDOM links between NAT/route and transparent VDOMs

Inter-VDOM links between NAT/route and transparent mode VDOMs can be useful for configurations where the NAT/route VDOMs that share a common Internet service route, which can be routed through a transparent VDOM that provides additional functionality, like common Security inspection, WAN optimization, explicit proxying and so on.

Other examples include:

- Performing SSL offloading in the transparent mode VDOM and providing Internet access through a NAT/route mode VDOM.
- Applying WAN optimization in a transparent mode VDOM and other security features in the NAT/route mode VDOM.
- Using a dedicated transparent mode VDOM for the explicit web proxy in front of a NAT/route mode VDOM that applies other security features.
- An ISP configuration with multiple per-tenant NAT/route mode VDOMs all sharing a single Internet connection but where the ISP only presents a single routed subnet. Each tenant can then be assigned an IP from the subnet for their respective VDOM link interface while using a single physical port to connect to the ISP router.

For more information about inter-VDOM links, please refer to the Virtual Domains handbook.

Replay traffic scenario

Situations can arise where an identical TCP packet enters twice the FortiGate via 2 different ports. This can be due to a firewall or other network device redirecting packets out on the same port it has received it.

The FortiGate will in this condition detect a replay packet and drop it.

If the network topology or culprit devices cannot be changed to avoid this, the workaround on the FortiGate can be to disable TCP replay verification packets.

```
config system global
    set anti-replay | loose | strict | disable |
```

end

The debug flow diagnosis output hereafter shows the message indicating this condition:

```
id=20085 trace_id=179 msg="vd-VDOM_VLAN1 received a packet(proto=6, 10.10.253.9:10709
>10.10.248.5:25) from TO_EXTERNAL ."
id=20085 trace_id=179 msg="Find an existing session, id-00041475, original direction"
id=20085 trace_id=179 msg="replay packet, drop"
```

For additional diagnosis and troubleshooting procedures, go to <http://kb.fortinet.com>.

Packet forwarding using Cisco protocols

In order to pass Cisco Discover Protocol (CDP) or Cisco VLAN Trunk Protocol (VTP) packets through a FortiGate in transparent mode, the parameter `stpforward` must be applied on the port configuration. VTP and CDP packets are sent to the destination MAC address 01-00-0C-CC-CC-CC.

A Cisco NATIVE VLAN carries CDP/VTP frames. The frames of this VLAN must be received on the FortiGate physical interfaces (not VLAN sub-interface). Physical interfaces are the only ones that can send/accept non-tagged packets.

The example below will allow CDP and VTP packets to be sent from port3 up to the Remote unit, through two VDOMs, via one physical port and three port aggregations.

Port and port aggregation configuration:

```
config system interface
  edit "port1"
    set vdom "VD1"
  next
  edit "port2"
    set vdom "VD1"
  next
  edit "port3"
    set vdom "VD1"
    set stpforward enable
  next
  edit "port5"
    set vdom "VD3"
  next
  edit "port6"
    set vdom "VD3"
  next
  edit "port17"
    set vdom "VD2"
  next
  edit "port18"
    set vdom "VD2"
  next
  edit "port19"
    set vdom "VD2"
  next
  edit "port20"
    set vdom "VD2"
  next
```

```

edit "LACP_VD2_IN"
    set vdom "VD2"
    set stpforward enable
    set type aggregate
    set member "port17" "port18"
next
edit "LACP_VD2_OUT"
    set vdom "VD2"
    set stpforward enable
    set type aggregate
    set member "port19" "port20"
next
edit "LACP_VD1"
    set vdom "VD1"
    set stpforward enable
    set type aggregate
    set member "port1" "port2"
next
end

```

When using aggregation, the `stpforward` setting needs to be applied only on the port aggregation level, not on the physical port

This will also forward regular Spanning Tree BPDUs

Verification with a sniffer trace:

```
FGT# diagnose sniffer packet any "" 4
```

```

41.365434 port3 in llc unnumbered, ui, flags [command], length 72
41.365437 LACP_VD1 out llc unnumbered, ui, flags [command], length 72
41.365439 port2 out llc unnumbered, ui, flags [command], length 72
41.365479 LACP_VD2_IN in llc unnumbered, ui, flags [command], length 72
41.365482 LACP_VD2_OUT out llc unnumbered, ui, flags [command], length 72
41.365484 port19 out llc unnumbered, ui, flags [command], length 72

```

See above the CDP packet flow from port3, LACP_VD1 (port2), LACP_VD2_IN, LACP_VD2_OUT (port19).

The following sniffer trace command will filter only CDP or VTP packets :

```
FGT# diagnose sniffer packet port_name "ether host 01-00-0C-CC-CC-CC"
```

Configuration example

Step 1: Create VLANs and forwarding domains

```
config system interface
  edit "vlan102_intern"
    set forward-domain 102
    set interface "port2"
    set vlanid 102
  next
  edit "vlan102_extern"
    set forward-domain 102
    set interface "port3"
    set vlanid 102
  next
  edit "vlan103_intern"
    set forward-domain 103
    set interface "port2"
    set vlanid 103
  next
  edit "vlan103_extern"
    set forward-domain 103
    set interface "port3"
    set vlanid 103
  next
end
```

Step 2: Create the appropriate firewall policies

```
config firewall policy
  edit 1
    set srcintf "vlan102_extern"
    set dstintf "vlan102_intern"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY" next
  edit 2
    set srcintf "vlan102_intern"
    set dstintf "vlan102_extern"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY" next
  edit 3
    set srcintf "vlan103_intern"
    set dstintf "vlan103_extern"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY" next
  edit 4
    set srcintf "vlan103_extern"
    set dstintf "vlan103_intern"
    set srcaddr "all"
    set dstaddr "all"
```

```
    set action accept
    set schedule "always"
    set service "ANY" next
end
```

Firewalls and security in transparent mode

This section contains information about using firewalls and security scanning in transparent mode. It contains the following topics:

- [Firewall policy look up](#)
- [Firewall session list](#)
- [Security scanning](#)

Firewall policy look up

In transparent mode, like in NAT/route mode, a firewall policy look up is based on the source and destination interfaces. The matching firewall policy will tell which actions to apply to the traffic, including logging and security scanning.

The FortiGate proceeds as follows to look for a matching firewall policy in transparent mode:

- **Step 1:** an Ethernet IP frame ingresses a port (or a VLAN on a port), corresponding to a specific bridge instance (from the port VDOM and Forwarding domain). This frame contains a destination MAC address that we will call MAC_D.
- **Step 2:** The FortiGate is making a MAC_D address lookup in the bridge instance to determine the port where MAC_D has been learned. This will be the destination interface.
- **Step 3:** The FortiGate is then looking for a firewall policy corresponding to the couple < source interface + destination interface >. If multiple policies with the same couple < source interface + destination interface > exist, the FortiGate screens all of them from TOP to BOTTOM (as displayed in the configuration), until a match is found. It is important to make sure that the most specific firewall policies are located at the top of the policy list, to make sure that traffic is matched to the appropriate policy.

Firewall session list

The flag **br** in the state line will indicate that this is a “bridged” session. See example below :

```
FGT# diagnose sys session list

session info: proto=17 proto_state=00 duration=59 expire=128 timeout=0 flags=000
00000 sockflag=00000000 sockport=0 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=
ha_id=0 hakey=0
policy_dir=0 tunnel=/
state=may_dirty br rem
statistic(bytes/packets/allow_err): org=385/5/1 reply=0/0/0 tuples=2
orgin->sink: org pre->post, reply pre->post dev=3->4/4->3 gwy=0.0.0.0/0.0.0.0
hook=pre dir=org act=noop 192.168.182.93:1025->4.2.2.1:53(0.0.0.0:0)
hook=post dir=reply act=noop 4.2.2.1:53->192.168.182.93:1025(0.0.0.0:0)
misc=0 policy_id=1 auth_info=0 chk_client_info=0 vd=1 serial=000006d3 tos=ff/ff
imp2p=0 app=0
dd_type=0 dd_rule_id=0
```

Security scanning

Security scanning occurs in the same manner in NAT/route mode and transparent mode. When a protection profile is enabled on a firewall policy for content inspection, the FortiGate acts like a transparent proxy for the protocols that need to be inspected.

The FortiGate will therefore intercept the TCP sessions and create its own session from client to server and server to client. The source and destination MAC addresses of the original L2 frames are however not altered in this communication, as described in the section Network operation : source MAC addresses in frames sent by or through the FortiGate.

Devices in the network communicating through the FortiGate do not know the presence of the FortiGate.

For more information about security scanning, see the *Security Profiles Handbook*.

IPsec VPN in transparent mode

This section contains information about configuring IPsec virtual private networks (VPNs) in transparent mode. It contains the following topics:

- [Using IPsec VPNs in transparent mode](#)
- [Example 1: Remote sites with different subnets](#)
- [Example 2: Remote sites on the same subnet](#)

Using IPsec VPNs in transparent mode

In transparent mode, IPsec VPN is supported in Policy-based configuration mode only.

IPsec VPN in transparent mode can be used in those scenarios:

- Encrypt data over routed networks without changing anything on the routers. See example 1.
- Encrypt data over a non-routed transport network (extension of a LAN for example). See example 2.

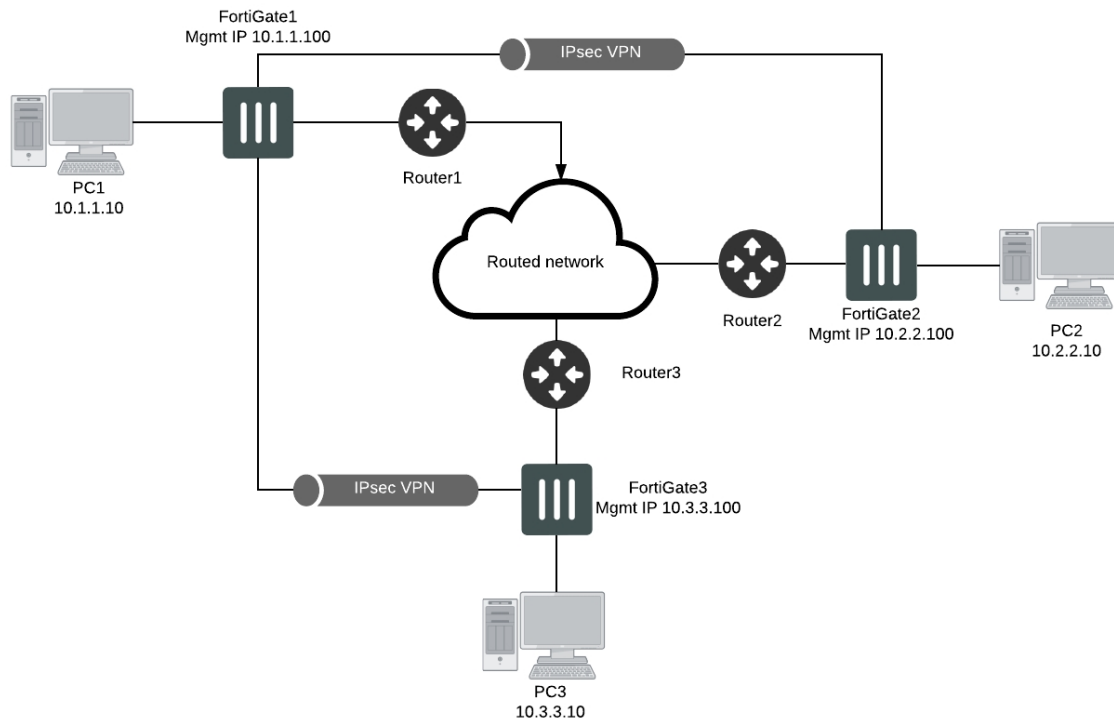

The following rules apply to IPsec in transparent mode:

- If both remote FortiGate IPsec gateways are not in the same broadcast domain (separated by routers):
 - The hosts on each side must be on different subnets.
 - The FortiGate management IP addresses must be in the same subnet as the local hosts. This is the preferred option.
- If both remote FortiGate IPsec gateways are in the same broadcast domain (separated by optical switches for examples), the hosts on each side can be :
 - On the same subnet
 - On different subnet if the appropriate static route is configured on the remote FortiGate
 - The FortiGate management IP addresses can be in any different subnet than the local hosts
- A firewall Policy with the action IPsec is used to send traffic to the remote device into the tunnel.
Therefore, it is important to place all remote devices on the appropriate ports of the FortiGate to allow a proper match < source interface + destination interface > . See section transparent mode Firewall processing for more details.

This scenario requires that the remote hosts located on the remote FortiGate's protected subnets have their MAC addresses hard coded in FortiGate's static MAC entry list. If this is not configured then it is expected to see outage in network communications.

Example 1: Remote sites with different subnets

This example provides a configuration example for IPsec VPN tunnels between three FortiGate in transparent Mode in different subnets, as well as some troubleshooting steps.

The expectation for this example is that PC1 will be able to communicate via the IPsec tunnels with PC2 and PC3, which are in different subnets.

The requirements for this example are:

- Because both FortiGate are not in the same broadcast domain (separated by routers), the hosts on each side must be on different subnets.
- FortiGate management IP addresses must be in the same subnet as the local hosts
- The default gateways (router1 ,router2, router3) for PC1 , PC2 and PC3 must be behind port2 in order for the FortiGate to match the appropriate Encrypt firewall policy (port1 --> port2)

Configuration of FortiGate 1 (FGT1):

Only relevant parts of configuration are provided.

```
config system settings
  set opmode transparent
  set manageip 10.1.1.100/255.255.255.0
end

config router static
  edit 1
    set gateway 10.1.1.254
```

```
    next
end

config firewall address
    edit "10.1.1.0/24"
        set subnet 10.1.1.0 255.255.255.0
    next
    edit "10.2.2.0/24"
        set subnet 10.2.2.0 255.255.255.0

Troubleshooting procedure

All steps given when PC1 pings PC2.

Verify if IPsec tunnels are up

```

FGT1 # diagnose vpn tunnel list

list all ipsec tunnel in vd 0
-----
name=to_FGT2 ver=0 serial=1 10.1.1.100:0->10.2.2.100:0 lgwy=dyn tun=tunnel mode= auto
bound_if=0
proxyid_num=1 child_num=0 refcnt=7 ilast=0 olast=0
stat: rxp=0 txp=0 rxb=0 txb=0
dpd: mode=active on=1 idle=5000ms retry=3 count=0 seqno=1455
natt: mode=none draft=0 interval=0 remote_port=0
proxyid=to_FGT2 proto=0 sa=0 ref=1 auto_negotiate=0 serial=5
  src: 10.1.1.0/255.255.255.0:0
  dst: 10.2.2.0/255.255.255.0:0

```

The above tunnel is down (output given as example)!

```

FGT2 # diagnose vpn tunnel list

list all ipsec tunnel in vd 0
-----
name=to_FGT1 10.2.2.100:0->10.1.1.100:0 lgwy=dyn tun=tunnel mode=auto bound_if=0

ah=sha1 key=20 e316113eb6ea03b014b3a5f9c1a3bd386637801a

```

The above tunnel is up!

Verify that destination local hosts are seen in the ARP table (necessary for IPsec despite being in TP mode)

```
FGT2 # get system arp
```

Address	Age(min)	Hardware Addr	Interface
10.2.2.10	2	00:50:56:00:76:04	root.b
10.2.2.254	0	00:09:0f:30:29:e4	root.b

Using the debug flow command on the initiator side (example on FortiGate1)

```
FGT1 # diagnose debug flow filter addr 10.1.1.10
FGT1 # diagnose debug flow show console enable
FGT1 # diagnose debug enable
FGT1 # diagnose debug flow trace start 50

id=36870 trace_id=617 msg="enter IPsec tunnel-to_FGT2"
id=36870 trace_id=617 msg="encrypted, and send to 10.2.2.100 with source 10.1.1.100"
id=36870 trace_id=617 msg="send out via dev-port2, dst-mac-00:09:0f:30:29:e0"
id=36870 trace_id=618 msg="vd-root received a packet(proto=1, 10.2.2.10:512->10.1.1.10:0) from port2."
id=36870 trace_id=618 msg="Find an existing session, id-00000636, reply direction"
id=36870 trace_id=618 msg="send out via dev-port1, dst-mac-00:50:56:00:76:03"
id=36870 trace_id=619 msg="vd-root received a packet(proto=1, 10.1.1.10:512->10.2.2.10:8) from port1."
id=36870 trace_id=619 msg="Find an existing session, id-00000636, original direction"
id=36870 trace_id=619 msg="enter IPsec tunnel-to_FGT2"
id=36870 trace_id=619 msg="encrypted, and send to 10.2.2.100 with source 10.1.1.100"
id=36870 trace_id=619 msg="send out via dev-port2, dst-mac-00:09:0f:30:29:e0"
id=36870 trace_id=620 msg="vd-root received a packet(proto=1, 10.2.2.10:512->10.1.1.10:0) from port2."
id=36870 trace_id=620 msg="Find an existing session, id-00000636, reply direction"
id=36870 trace_id=620 msg="send out via dev-port1, dst-mac-00:50:56:00:76:03"
```

The message "id=36870 trace_id=615 msg="SA is not ready yet, drop" simply means that the tunnel was not up yet.

Using the debug flow command on the receiver side (example on FortiGate2)

```

FGT2 # diagnose debug flow filter addr 10.1.1.10
FGT2 # diagnose debug flow show console enable
FGT2 # diagnose debug enable
FGT2 # diagnose debug flow trace start 50

FGT2 # id=36870 trace_id=51 msg="vd-root received a packet(proto=1, 10.1.1.10:512->10.2.2.10:8) from port2."
id=36870 trace_id=51 msg="allocate a new session-00000435"
id=36870 trace_id=51 msg="Allowed by Policy-1:"
id=36870 trace_id=51 msg="send out via dev-port1, dst-mac-00:50:56:00:76:04"
id=36870 trace_id=52 msg="vd-root received a packet(proto=1, 10.2.2.10:512->10.1.1.10:0) from port1."
id=36870 trace_id=52 msg="Find an existing session, id-00000435, reply direction"
id=36870 trace_id=52 msg="enter IPsec tunnel-to_FGT1"
id=36870 trace_id=52 msg="encrypted, and send to 10.1.1.100 with source 10.2.2.100"
id=36870 trace_id=52 msg="send out via dev-port2, dst-mac-00:09:0f:30:29:e4"

```

Using the sniffer trace (example on FortiGate2)

```

FGT2 # diagnose sniffer packet any "host 10.2.2.10" 4

9.460021 root.b out arp who-has 10.2.2.10 tell 10.2.2.100

50.510524 port1 in 10.2.2.10 -> 10.1.1.10: icmp: echo reply

```

The above ARP process in transparent mode with IPsec is allowing the FortiGate to:

- Identify the MAC address of the destination device 10.2.2.10
- Populate the MAC table (see below), which in turn will give a destination interface and allow a Firewall policy look-up

Check the FDB entries for the destination

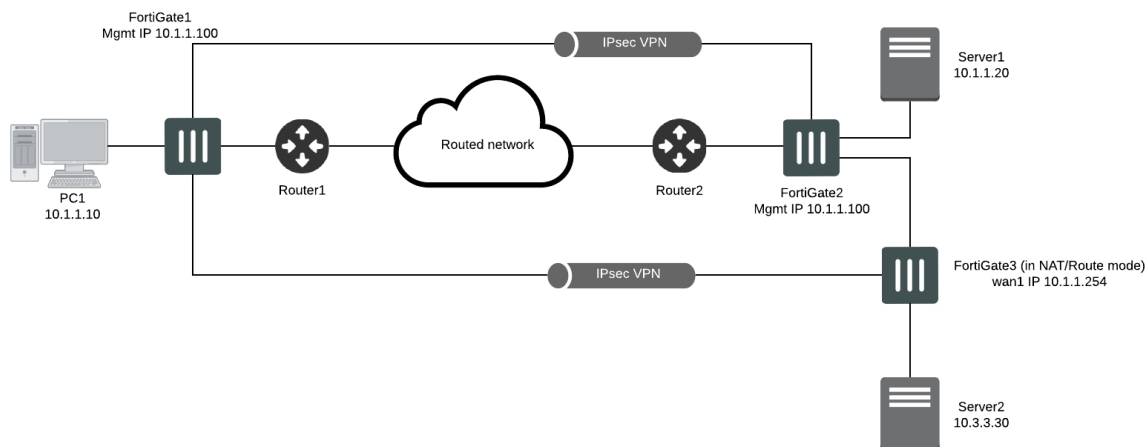

```

FGT2 # diagnose netlink brctl name host root.b

port no   device  devname  mac addr          ttl
[...]
1         2        port1    00:50:56:00:76:04  0

```

Example 2: Remote sites on the same subnet

This example provides a configuration example for IPsec VPN tunnels between two FortiGate in transparent Mode in the same subnet separated by a L2 transparent network and one remote subnet on the second site.

This scenario requires that PC1's MAC address is added to the FortiGate static MAC table. The preferred scenario would be to have a router installed between the FortiGate devices.

The expectation for this example is that PC1 will be able to communicate via the IPsec tunnel with Server1 in the same subnet, and Server2 in a different subnet.

The requirements for this example are:

- The default gateway (FGT3) for PC1 and all remote device must be behind port2 of FGT1, in order for this FortiGate to match the appropriate Encrypt firewall policy (port1 --> port2)
- Despite being in transparent mode, **FGT2 must have a valid route to Server2**
- FGT3 is used as a router between subnet 10.1.1.0/24 and 10.3.3.0/24.

PC1 MAC address added to FGT2 static MAC entries.

Server1 MAC address added to FGT1 static MAC entries.

Configuration of FortiGate 1 (FGT1):

Only relevant parts of configuration are provided.

```
config system settings
    set opmode transparent
    set manageip 10.1.1.100/255.255.255.0
end

config router static
    edit 1
        set gateway 10.1.1.252
    next
end
```

```
config system mac-address-table
  edit 00:50:56:00:76:04 ==>Server1
    set interface port2
  next
end

config firewall address
  edit "all"
  next
  edit "Server1"
    set subnet 10.1.1.20 255.255.255.255
  next

    set subnet 10.3.3.30 255.255.255.255
  next
  edit "10.1.1.0/24"
    set subnet 10.1.1.0 255.255.255.0
  next
  edit "gateway"
    set subnet 10.1.1.254 255.255.255.255
  next
end

config vpn ipsec phase1
  edit "to_FGT2"
    set proposal 3des-sha1 aes128-sha1 des-md5
    set remote-gw 10.1.1.200
    set psksecret fortinet
  next
end

config vpn ipsec phase2
  edit "to_FGT2"
    set keepalive enable
    set phasename "to_FGT2"
    set proposal 3des-sha1 aes128-sha1
    set src-subnet 10.1.1.0 255.255.255.0
  next
end

config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "10.1.1.0/24"
    set dstaddr "Server1"
    set action ipsec
    set schedule "always"
    set service "ANY"
    set inbound enable
    set outbound enable
    set vpntunnel "to_FGT2"
  next
  edit 2
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "10.1.1.0/24"
```

```
        set dstaddr "Server2"
        set action ipsec
        set schedule "always"
        set service "ANY"
        set inbound enable
        set outbound enable
        set vpntunnel "to_FGT2"
    next
edit 3
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "10.1.1.0/24"
    set dstaddr "gateway"
    set action ipsec
    set schedule "always"
    set service "ANY"
    set inbound enable
    set outbound enable
    set vpntunnel "to_FGT2"
next
end
```

Firewall Policy 3 is not mandatory and is only used to allow PC1 to test a ping reachability to its default gateway 10.1.1.254.

Configuration of FortiGate 2 (FGT2):

Only relevant parts of configuration are provided.

```
config system settings
    set opmode transparent
    set manageip 10.1.1.200/255.255.255.0
end

config router static
    edit 1
        set gateway 10.1.1.252
    next
    edit 2
        set dst 10.3.3.0 255.255.255.0
        set gateway 10.1.1.254
    next
end

config system mac-address-table
    edit 00:50:56:00:76:03
        set interface wan1
    next
end

config firewall address
    edit "all"
    next
    edit "PC1"
```

```
        set subnet 10.1.1.10 255.255.255.255
    next
    edit "10.1.1.0/24"
        set subnet 10.1.1.0 255.255.255.0
    next
    edit "10.3.3.0/24"
        set subnet 10.3.3.0 255.255.255.0
    next
end

config vpn ipsec phase1
    edit "to_FGT1"
        set proposal 3des-sha1 aes128-sha1 des-md5
        set remote-gw 10.1.1.100
        set psksecret fortinet
    next
end

config vpn ipsec phase2
    edit "to_FGT1"
        set keepalive enable
        set phaselname "to_FGT1"
        set proposal 3des-sha1 aes128-sha1
        set dst-subnet 10.1.1.0 255.255.255.0
    next
end

config firewall policy
    edit 1
        set srcintf "internal"
        set dstintf "wan1"
        set srcaddr "10.1.1.0/24" set dstaddr "PC1"
        set action ipsec
        set schedule "always"
        set service "ANY" set inbound enable
        set outbound enable
        set vpntunnel "to_FGT1"
    next
    edit 2
        set srcintf "internal"
        set dstintf "wan1"
        set srcaddr "10.3.3.0/24" set dstaddr "PC1"
        set action ipsec
        set schedule "always"
        set service "ANY" set inbound enable
        set outbound enable
        set vpntunnel "to_FGT1"
    next
end
```

Troubleshooting procedure

Check the ARP entries of PC1

```
C:\ arp -a
```

```
Interface: 10.1.1.10 --- 0x20003
```

Internet Address	Physical Address	Type
10.1.1.20	00-50-56-00-76-04	dynamic
10.1.1.254	00-09-0f-85-3f-c8	dynamic

MAC address **00-09-0f-85-3f-c8** is the FGT3 interface in subnet 10.1.1.0/24.

FDB entries of FGT1

```
FGT1 (global) # diagnose netlink brctl name host Vdom1.b
```

```
show bridge control interface Vdom1.b host. fdb:
size=256, used=6, num=6, depth=1
Bridge Vdom1.b host table
```

port no	device	devname	mac addr	tvl	attributes
1	10	port1	00:50:56:00:76:03	0	
2	9	port2	00:50:56:00:76:04	44	static
2	9	port2	00:09:0f:85:3f:c8	13	
1	10	port1	00:09:0f:88:2f:69	0	Local Static
2	9	port2	00:09:0f:88:2f:68	0	Local Static
2	9	port2	00:09:0f:23:01:d6	0	

MAC address **00:09:0f:23:01:d6** is “internal” port MAC address of FGT2 00:09:0F:23:01:D6. This is the MAC address used for management in the transparent mode VDOM of FGT2, chosen between the lowest MAC address between wan1 (00:09:0F:78:00:74) and internal (00:09:0F:23:01:D6).

ARP entries of FGT2

```
FGT2 (TP) # get system arp
```

Address	Age(min)	Hardware Addr	Interface
10.1.1.20	82	00:50:56:00:76:04	TP.b
10.1.1.100	13	00:09:0f:88:2f:68	TP.b
10.1.1.254	76	00:09:0f:85:3f:c8	TP.b

it is important to have the entry for 10.1.1.254 which is the route to 10.3.3.0/24 .

IPsec Tunnel verification on FGT1

```
FGT1 (Vdom1) # diagnose vpn tunnel list
```

```
list all ipsec tunnel in vd 3
```

```
-----

```

From the above trace, the MAC address **0009 0f88 2f68** is the MAC address of FGT1 port2 . This is the MAC address used for management in the transparent mode VDOM of FGT1, chosen between the lowest MAC address between port1 (00:09:0F:88:2F:69) and port2 ((00:09:0F:88:2F:68).

Debug flow on FGT1 filtered on Server3

```

FGT1 (Vdom1) # diagnose debug flow filter addr 10.3.3.30
FGT1 (Vdom1) # diagnose debug flow show console enable

```

```
FGT1 (Vdom1) # diagnose debug enable
FGT1 (Vdom1) # diagnose debug flow trace start 10

id=20085 trace_id=11 msg="vd-Vdom1 received a packet(proto=1, 10.1.1.10:512->10.3.3.30:8)
    from port1."
id=20085 trace_id=11 msg="Find an existing session, id-00004e85, original direction"
id=20085 trace_id=11 msg="enter IPsec tunnel-to_FGT2"
id=20085 trace_id=11 msg="encrypted, and send to 10.1.1.200 with source 10.1.1.100"
id=20085 trace_id=11 msg="send out via dev-port2, dst-mac-00:09:0f:23:01:d6"
id=20085 trace_id=12 msg="vd-Vdom1 received a packet(proto=1, 10.3.3.30:512->10.1.1.10:0)
    from port2."

id=20085 trace_id=12 msg="send out via dev-port1, dst-mac-00:50:56:00:76:03"
```

From the trace above, **dst-mac-00:09:0f:23:01:d6** is "internal" port MAC address of FGT2 00:09:0F:23:01:D6. This is the MAC address used for management in the transparent mode VDOM of FGT2, chosen between the lowest MAC address between wan1 (00:09:0F:78:00:74) and internal (00:09:0F:23:01:D6).

Using FortiManager and FortiAnalyzer

FortiManager and FortiAnalyzer are supported similarly to NAT/route mode. For more information about this please consult the Fortinet documentation at <http://docs.fortinet.com> or the Knowledge base at <http://kb.fortinet.com>.

Establishing a communication to a FortiAnalyzer is done as per the example hereafter (from global level if VDOM is enabled). This setting is independent from being in transparent mode. However, as stated earlier in this section the management VDOM must have IP connectivity to the FortiAnalyzer.

```
FGT (global) # show system fortianalyzer

config system fortianalyzer
    set status enable
    set server 10.2.2.2
end
```

High availability in transparent mode

This section contains information about configuring high availability in transparent mode. It contains the following topics:

- [Virtual clustering](#)
- [MAC address assignment](#)

For complete information about HA, please refer to the FortiGate Administration Guide or the HA Technical guides available at <http://docs.fortinet.com> or the Knowledge Base at <http://kb.fortinet.com>.

Any other statement and feature description in this document apply to a FortiGate Cluster running in Active-Passive mode.

Virtual clustering

If VDOM (virtual domain) is enabled on a cluster operating transparent mode, HA virtual clustering can be configured in active-passive mode.

This will provide:

- Failover protection between two instances of a VDOM operating on two different FortiGate in the cluster.
- Load balancing between the FortiGate devices on a per-VDOM basis.

The roles have been defined such as, in normal operation:

- FortiGate1 is Master for VDOM1 and Slave for VDOM2
- FortiGate2 is Master for VDOM2 and Slave for VDOM1

In case of a failure or reboot of a FortiGate, the remaining unit will become Master for VDOM1 and VDOM2.

The VDOMs given in this example are showing physical ports but a VDOM can also include VLAN interfaces.

The L2 connectivity between the FortiGate is showing 4 separate L2 switches, but it could also be one single switch on each side configured with appropriate VLANs.

Configuration example

- FortiGate1:

```
FGT1 (global) # show system ha

config system ha
    set mode a-p
    set hbdev "port5" 0 "port6" 0
```

```
set vcluster2 enable
set override disable
set priority 200
    config secondary-vcluster
        set override enable
        set priority 100
        set vdom "VDOM2"
    end
end
```

- **FortiGate2:**

```
FGT2 (global) # show system ha

config system ha
    set mode a-p
    set hbdev "port5" 0 "port6" 0
    set vcluster2 enable
    set override disable
    set priority 200
        config secondary-vcluster
            set override enable
            set priority 100
            set vdom "VDOM2"
        end
end
```

MAC address assignment

If a cluster is operating in transparent mode, the FortiGate Clustering Protocol (FGCP) assigns a virtual MAC address for the Master unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

Best practices

1. Create forwarding domains when VLANs are used and set `vlanforward` to `disable` on all relevant physical interface.
2. The forward-domain ID can be different to the VLAN ID, but it is recommended for troubleshooting and readability to keep them the same.
3. Only interfaces from the same forwarding domains can have firewall policies between each others.
4. In order to allow IVL (independent VLAN learning), the VLANs must be placed in separate forwarding domains.
5. If an out-of-band management is desired, use if possible a VDOM in NAT/route mode as management VDOM and create (an) other transparent mode VDOM(s) for the user traffic.
6. As Spanning Tree BPDUs are not forwarded by default, insert the FortiGate with caution to avoid L2 loops.
7. Multicast packets are not forwarded by default; this might cause routing protocols (RIP2, OSPF) disruption.
8. When using HSRP or VRRP configure static MAC entries for the Virtual MAC addresses.

Chapter 27 - Troubleshooting

This handbook chapter presents troubleshooting and problem solving issues that may help you with your FortiGate and contains the following sections:

- ["Troubleshooting methodologies" on page 2877](#) walks you through best practice concepts of FortiOS troubleshooting.
- ["Troubleshooting tools" on page 2881](#) describes some of the basic commands and parts of FortiOS that can help you with troubleshooting.
- ["Troubleshooting tips" on page 2908](#) presents most of the common issues and how to address them.
- ["Troubleshooting resources" on page 2936](#) identifies Fortinet's resources for troubleshooting.

Troubleshooting methodologies

This section explains how to prepare for troubleshooting, create a troubleshooting plan, and where to find additional resources.

The following topics are covered:

- [Ensure you have administrator-level access to required equipment](#)
- [Establish a baseline](#)
- [Define the problem](#)
- [Create a troubleshooting plan](#)
- [Obtain any required equipment](#)
- [Consult Fortinet resources](#)

Ensure you have administrator-level access to required equipment

Before troubleshooting your FortiGate, you will need administrator access to the equipment. If you're a client on a FortiGate that has virtual domains (VDOMs) enabled, you can often troubleshoot within your own VDOM. However, you should inform the super admin for the FortiGate that you'll be performing troubleshooting tasks.

Also, you may need access to other networking equipment, such as switches, routers, and servers, to carry out tests. If you don't have access to this equipment, contact your network administrator for assistance.

Establish a baseline

A FortiGate operates at all layers of the OSI model. For this reason, troubleshooting problems can become complex. Establishing baseline parameters for your system before a problem occurs helps to reduce the complexity when you need to troubleshoot.

Many of the guiding questions in the following sections serve to compare the current problem situation to normal operation on your FortiGate. A best practice is to establish and record the normal operating status. Regular operation data shows trends, and allows you to see when changes occur and when there may be a problem. You can gather this data by using logs and SNMP tools to monitor the system performance or by regularly running information gathering commands and saving the output.

Back up your FortiOS configuration on a regular basis. This is a good practice and not only for troubleshooting. You can restore the backed up configuration as needed and save the time and effort of recreating it from the factory default settings.

You can use the following CLI commands to obtain normal operating data for a FortiGate:

```
get system status
```

Displays firmware versions and FortiGuard engine versions, and other system information

<code>get system performance status</code>	Displays CPU and memory states, average network usage, average sessions and session setup rate, virus caught, IPS attacks blocked, and uptime
<code>get hardware memory</code>	Displays information about memory
<code>get system session status</code>	Displays total number of sessions
<code>get router info routing-table all</code>	Displays all the routes in the routing table, including their type, source, and other useful data
<code>get ips session</code>	Displays memory used and maximum amount available to IPS as well and counts
<code>get webfilter ftgd-statistics</code>	Displays a list of FortiGuard related counts of status, errors, and other data
<code>diagnose system session list</code>	Displays the list of current detailed sessions
<code>show system dns</code>	Displays the configured DNS servers
<code>diagnose system ntp status</code>	Displays information about NTP servers

These commands are just a sample. You can run any commands for information gathering that apply to your system. For example, if you have active VPN connections, use the `get vpn *` series of commands to get more information about them.

To see an extensive snapshot of your system, you can use the `execute tac report` command. This command runs many diagnostic commands for specific configurations. Regardless of the features deployed on your FortiGate, this command records the current state of each feature. Then, if you need to perform troubleshooting later, you can run the same command again and compare the differences to quickly identify any suspicious output.

Define the problem

The following questions help you define the problem. Be as specific as possible with your answers. Once you define the problem, you can search for a solution and then create a plan for how to solve it.

- **What is the problem?**

The problem being observed is not necessarily the actual problem. You should determine where the problem lies before starting to troubleshoot the FortiGate.

- **Was the device working before?**

If the device never worked, it might be defective. For more information, see [Troubleshooting your FortiGate Installation](#) in the [Getting Started](#) chapter.

- **Can you reproduce the problem ?**

If the problem is intermittent, it may be dependent on system load. Note that it may be difficult to troubleshoot an intermittent problem because it's difficult to reproduce.

- **What has changed?**

Don't assume that nothing has changed in the network. Use the FortiGate event log to identify any possible configuration changes. There may be changes in the operating environment. For example, there might be a gradual increase in load as more sites are forwarded through the firewall.

If something has changed, roll back the change and assess the impact.

- **What is the scope of the problem?**

After you isolate the problem, determine what applications, users, devices, and operating systems the problem affects.

- What's not working? Be specific.
- Is there more than one thing that isn't working?
- Is it partly working? If so, what parts are working?
- Is it a connectivity issue for the entire device, or is there an application that isn't reaching the Internet?
- Where did the problem occur?
- When did the problem occur and to which users or groups of users?
- What components are involved?
- What applications are affected?
- Can you use a packet sniffer to trace the problem?
- Can you use system debugging or look in the session table to trace the problem?
- Do any of the log files indicate a failure has occurred?

The answers to these questions help you narrow down the problem and identify what you should check during your troubleshooting. The more things you can eliminate, the fewer things you need to check during troubleshooting. For this reason, be as specific and accurate as you can when you gather information.

Create a troubleshooting plan

Once you define the problem and gather facts, you can create a troubleshooting plan to solve the problem.

You should list all possible causes of the problem and how you can test for each cause.

The plan acts as a checklist so that you know what you've tried and what's left to check. This is also important to have if more than one person is performing troubleshooting tasks.

Be ready to add to your plan, as needed.

Providing supporting elements

If you contact Fortinet's Technology Assistance Center (TAC), be prepared to provide the following information:

- Firmware build version (use the `get system status` command)
- Network topology diagram
- Recent configuration file
- Recent debug log (optional)
- Summary of troubleshooting steps that you've already taken and the results.

Don't provide the output from the `exec tac` report unless TAC requests it. The output from this command is very large and isn't required in many cases.

Obtain any required equipment

To test your solution, you may require additional networking equipment, computers, or other equipment.

Network administrators usually have additional networking equipment available to loan you, or a lab where you can bring the FortiGate unit to test.

If you don't have access to equipment, check for shareware applications that can perform the same tasks. Often, there are software solutions that you can use when hardware is too expensive.

Consult Fortinet resources

After you define your problem, create a plan to find a solution, and carry out that plan. If you can't resolve the problem, see ["Troubleshooting resources" on page 2936](#).

Troubleshooting tools

FortiOS provides several tools that can help you troubleshoot both hardware and software issues. These tools include diagnostics and ports. You use ports when you need to understand the traffic coming in and going out on a specific port. For example, the FortiGate uses port UDP 53 for DNS and RBL lookups.

This section contains the following topics:

- [FortiOS diagnostics](#)
- [FortiOS ports](#)
- [FortiAnalyzer/FortiManager ports](#)
- [FortiGuard troubleshooting](#)

FortiOS diagnostics

FortiOS has a collection of diagnostic commands that you can use to troubleshoot and monitor the performance of your network. The `get` and `diagnose` CLI commands are the two main groups of diagnostic commands. Both commands display information about system resources, connections, and settings that allow you to locate problems or monitor system performance.

This topic includes diagnostics commands to help with:

- [Date and time](#)
- [Resource usage](#)
- [Proxy operation](#)
- [Hardware NIC](#)
- [Traffic trace](#)
- [Session table](#)
- [Firewall session setup rate](#)
- [Finding object dependencies](#)
- [Flow trace](#)
- [Packet sniffing and packet capture](#)
- [NPU-based interfaces](#)
- [Debug command](#)
- [The execute tac report command](#)
- [Other commands](#)

Date and time

The system date and time are important for FortiGuard services, logging events, and sending alerts. The wrong time makes the log entries confusing and difficult to use.

Use Network Time Protocol (NTP) to set the date and time, if possible. This is an automatic method that doesn't require manual intervention. However, you must ensure that the port is allowed through the firewalls on your network. FortiToken synchronization requires NTP in many situations.

How to set the date and time - GUI

1. Go to the **System Information** widget on the **Dashboard**. The date and time are displayed next to **System Time**.
2. To adjust the date and time settings, go to **System > Settings**.
3. In **System Time**, you can set the time zone, date and time, and select **NTP usage**.

How to check the date and time - CLI

You can check the date and time using the CLI commands `execute date` and `execute time`.

```
config system global
    set timezone <integer>
end
config system ntp
    set type custom
    config ntpserver
        edit 1
            set server "ntp1.fortinet.net"
        next
        edit 2
            set server "ntp2.fortinet.net"
        next
    end
set ntpsync enable
set syncinterval 60
end
```

Use the `set timezone ?` command to display a list of timezones and the integers that represent them.

Resource usage

Each program that runs on a computer has one or more processes associated with it. For example, if you open a Telnet program, it has an associated Telnet process. The same is true in FortiOS. All processes share the system resources in FortiOS, including memory and CPU.

Use the `get system performance status` command to show the FortiOS performance status.

Sample output:

```
FGT# get system performance status
CPU states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
CPU0 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
CPU1 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
CPU2 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
CPU3 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
Memory: 4050332k total, 527148k used (13%), 3381312k free (83%), 141872k freeable (3%)
Average network usage: 41 / 28 kbps in 1 minute, 54 / 44 kbps in 10 minutes, 42 / 34
kbps in 30 minutes
Average sessions: 33 sessions in 1 minute, 48 sessions in 10 minutes, 38 sessions in 30
minutes
Average session setup rate: 0 sessions per second in last 1 minute, 0 sessions per
second in last 10 minutes, 0 sessions per second in last 30 minutes
Virus caught: 0 total in 1 minute
IPS attacks blocked: 0 total in 1 minute
```

Uptime: 0 days, 22 hours, 59 minutes

Monitor the CPU and memory usage of internal processes, using the following command:

```
get system performance top <delay> <max_lines>
```

The data that the command lists includes the name of the daemon, the process ID, whether the process is sleeping or running, the CPU use percentage, and the memory use percentage.

Sample output:

```
get system performance top 10 100
Run Time: 0 days, 23 hours and 4 minutes
OU, ON, OS, 100I, OWA, OHI, OSI, OST; 3955T, 3298F

```

Proxy operation

Monitor proxy operations, using the following command:

```
diagnose test application <application> <option>
```

To display a list of available <application> values, enter:

```
diagnose test application ?
```

The <option> value depends on the application value that you use in the command. To display a list of available <option> values, enter:

```
diagnose test application <application> ?
```

For example, if the application is http, the CLI command that displays the <option> values is:

```
diagnose test application http ?
```

Hardware NIC

To monitor hardware network operations, use the following command:

```
diagnose hardware deviceinfo nic <interface>
```

The information that this command shows is important because errors at the interface indicate data link or physical layer issues which may impact the performance of the FortiGate.

The following example shows a sample output when you set <interface> to lan:

```
System_Device_Name lan
Current_HWaddr 00:09:0f:68:35:60
Permanent_HWaddr 00:09:0f:68:35:60
State up
Link up
Speed 100
Duplex full
[.....]
Rx_Packets=5685708
Tx_Packets=4107073
Rx_Bytes=617908014
Tx_Bytes=1269751248
Rx_Errors=0
Tx_Errors=0
Rx_Dropped=0
Tx_Dropped=0
[....]
```

The `diagnose hardware deviceinfo nic` command displays a list of error names and values that are related to hardware. The following table describes possible hardware errors:

Field	Description
Rx_Errors = rx error count	Bad frame was marked as error by PHY
Rx_CRC_Errors + Rx_Length_Errors - Rx_Align_Errors	This error is only valid in 10/100M mode
Rx_Dropped or Rx_No_Buffer_Count	Running out of buffer space
Rx_Missed_Errors	Equals Rx_FIFO_Errors + CEXTERR (Carrier Extension Error Count); only valid in 1000M mode, which is marked by PHY
Tx_Errors = Tx_Aborted_ Errors	ECOL (Excessive Collisions Count); only valid in half-duplex mode

Field	Description
	Late Collisions (LATECOL) Count
Tx_Window_Errors	Late collisions are collisions that occur after 64-byte time into the transmission of the packet while working in 10 to 100 Mb/s data rate and 512-byte time into the transmission of the packet while working in the 1,000 Mb/s data rate. This register only increments if transmits are enabled and the device is in half-duplex mode.
Rx_Dropped	See Rx_Errors
Tx_Dropped	Not defined
Collisions	Total number of collisions experienced by the transmitter; valid in half-duplex mode
Rx_Length_Errors	Transmission length error
Rx_Over_Errors	Not defined
Rx_CRC_Errors	Frame CRC error
Rx_Frame_Errors	Same as Rx_Align_Errors This error is only valid in 10/100M mode.
Rx_FIFO_Errors	Same as Rx_Missed_Errors - a missed packet count
Tx_Aborted_Errors	See Tx_Errors
Tx_Carrier_Errors	The PHY should assert the internal carrier sense signal during every transmission. Failure to do so may indicate that the link has failed or the PHY has an incorrect link configuration. This register only increments if transmits are enabled. This register isn't valid in internal SerDes 1 mode (TBI mode for the 82544GC/EI) and is valid only when the Ethernet controller is operating at full duplex.
Tx_FIFO_Errors	Not defined
Tx_Heartbeat_Errors	Not defined
Tx_Window_Errors	See LATECOL
Tx_Single_Collision_Frames	Counts the number of times that a successfully transmitted packet encountered a single collision The value increments only if transmits are enabled and the Ethernet controller is in half-duplex mode.

Field	Description
Tx_Multiple_Collision_Frames	A Multiple Collision Count which indicates the number of times that a transmit encountered more than one collision, but less than 16. The value increments only if transmits are enabled and the Ethernet controller is in half-duplex mode.
Tx_Deferred	Counts defer events A deferred event occurs when the transmitter can't immediately send a packet due to the medium being busy because another device is transmitting, the IPG timer hasn't expired, half-duplex deferral events are occurring, XOFF frames are being received, or the link isn't up. This register only increments if transmits are enabled. This counter doesn't increment for streaming transmits that are deferred due to TX IPG.
Rx_Frame_Too_Longs	The Rx frame is oversized
Rx_Frame_Too_Shots	The Rx frame is too short
Rx_Align_Errors	This error is only valid in 10/100M mode
Symbol Error Count	Counts the number of symbol errors between reads - SYMERRS. The count increases for every bad symbol that's received, whether or not a packet is currently being received and whether or not the link is up. This register increments only in internal SerDes mode.

Traffic trace

Traffic tracing allows you to follow a specific packet stream. This is useful to confirm that packets are taking the route you expect them to take on your network.

View the characteristics of a traffic session through specific security policies using:

```
diagnose system session
```

Trace per-packet operations for flow tracing using:

```
diagnose debug flow
```

Trace per-Ethernet frame using:

```
diagnose sniffer packet
```

Trace a route from a FortiGate to a destination IP address using:

```
# execute traceroute www.fortinet.com
traceroute to www.fortinet.com (66.171.121.34), 32 hops max, 84 byte packets
1 172.20.120.2 0.637 ms 0.653 ms 0.279 ms
2 209.87.254.221 <static-209-87-254-221.storm.ca> 2.448 ms 2.519 ms 2.458 ms
3 209.87.239.129 <core-2-g0-2.storm.ca> 2.917 ms 2.828 ms 9.324 ms
4 209.87.239.199 <core-3-bdi1739.storm.ca> 13.248 ms 12.401 ms 13.009 ms
5 216.66.41.113 <v502.core1.tor1.he.net> 17.181 ms 12.422 ms 12.268 ms
6 184.105.80.9 <100ge1-2.core1.nyc4.he.net> 21.355 ms 21.518 ms 21.597 ms

```

Session table

A session is a communication channel between two devices or applications across the network. Sessions allow FortiOS to inspect and act on a sequential group of packets in a session all together instead of inspecting each packet individually. Each of these sessions has an entry in the session table that includes important information about the session.

Use as a tool

Session tables are useful troubleshooting tools because they allow you to verify open connections. For example, if you have a web browser open to browse the Fortinet website, you would expect a session entry from your computer, on port 80, to the IP address for the Fortinet website. Another troubleshooting method is if there are too many sessions for FortiOS to process, you can examine the session table for evidence why this is happening.

You can view the FortiGate session table from either the FortiGate GUI or CLI. The most useful troubleshooting data comes from the CLI. The session table in the GUI also provides useful summary information, particularly the current policy number that the session is using.

GUI session information

You can view session information by going to the **FortiView** page. Read more about [FortiView consoles](#) in the Handbook's FortiView chapter.

How to find which security policy a specific connection is using

Every program and device on your network must have a communication channel, or session, open to pass information. The FortiGate manages these sessions with features such as traffic shaping, antivirus scanning, and blocking known bad web sites. Each session has an entry in the session table.

You may want to find information for a specific session for troubleshooting. For example, if a secure web browser session isn't working properly, you can check the session table to ensure the session is still active and going to the proper address. The session table can also tell you the security policy number it matches, so you can check what's happening in that policy.

1. Know your connection information.

You need to be able to identify the session you want. For this, you need the source IP address (usually your computer), the destination IP address (if you have it), and the port number which is determined by the program that you're using. Some common ports are:

- Port 80 (HTTP for web browsing),
- Port 22 (SSH used for secure login and file transfers)
- Port 23 (Telnet for a text connection)
- Port 443 (HTTPS for secure web browsing)

2. Find your session and policy ID.

Go to **FortiView > All Sessions**. Find your session by finding your source IP address, destination IP address (if you have it), and port number. The policy ID is listed after the destination information. If the list of sessions is very long, you can filter the list to make it easier to find your session.

3. When there are many sessions, use a filter to help you find your session.

If there are multiple pages of sessions, it's difficult to find a single session. You can use a filter to block out sessions that you don't want. Click the search icon on the column heading to select the filter. Select **Source IP** and enter your source IP address. Now, only sessions that originate from your IP address are displayed in the session table. If the list is still too long, you can do the same for the **Source port**. That makes it easy to find your session and the security policy ID.

CLI session information

The session table output that the `diagnose system session list` command generates is very large. You can use filters to display only the session data that you're interested in.

An entry is placed in the session table for each traffic session passing through a security policy. The following command lists the information for a session in the table:

```
diagnose system session list
```

The filter option displays specific information, for example:

```
diagnose system session filter <option>
```

The values for `<option>` include the following:

<code>clear</code>	Clear session filter
<code>dintf</code>	Destination interface
<code>dport</code>	Destination port
<code>dst</code>	Destination IP address
<code>duration</code>	Duration of the session
<code>expire</code>	Expire
<code>negate</code>	Inverse filter
<code>nport</code>	NAT'd source port
<code>nsrc</code>	NAT'd source ip address
<code>policy</code>	Policy ID
<code>proto</code>	Protocol number
<code>proto-state</code>	Protocol state

<code>session-state1</code>	Session state1
<code>session-state2</code>	Session state2
<code>sintf</code>	Source interface
<code>sport</code>	Source port
<code>src</code>	Source IP address
<code>vd</code>	Index of virtual domain, -1 matches all

Even though UDP is a sessionless protocol, the FortiGate keeps track of the following states:

- When UDP reply doesn't have a value of 0
- When UDP reply has a value of 1

The following table displays firewall session states from the session table:

State	Description
<code>log</code>	Session is being logged
<code>local</code>	Session is originated from or destined for local stack
<code>ext</code>	Session is created by a firewall session helper
<code>may_dirty</code>	Session is created by a policy For example, the session for <code>ftp control channel</code> will have this state but <code>ftp data channel</code> won't. This is also seen when NAT is enabled.
<code>ndr</code>	Session will be checked by IPS signature
<code>nds</code>	Session will be checked by IPS anomaly
<code>br</code>	Session is being bridged (TP) mode

Firewall session setup rate

The number of sessions that can be established in a set period of time is useful information. A session is an end-to-end TCP/IP connection for communication with a limited lifespan. If you record the setup rate during normal operation, when you experience problems you can compare the baseline setup rate to the rate that occurs when you're troubleshooting. This can be a useful step to help you define your problem.

A reduced firewall session setup rate can be the result of a number of things, such as a lack of system resources on the FortiGate or reaching the limit of your session count for your VDOM.

To view your session setup rate method 1 - CLI

```
FGT# get system performance status
CPU states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
```

```

CPU0 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
CPU1 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
CPU2 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
CPU3 states: 0% user 0% system 0% nice 100% idle 0% iowait 0% irq 0% softirq
Memory: 4050332k total, 530512k used (13%), 3376844k free (83%), 142976k freeable (3%)
Average network usage: 131 / 90 kbps in 1 minute, 26 / 15 kbps in 10 minutes, 49 / 42
kbps in 30 minutes
Average sessions: 80 sessions in 1 minute, 30 sessions in 10 minutes, 42 sessions in 30
minutes
Average session setup rate: 3 sessions per second in last 1 minute, 0 sessions per
second in last 10 minutes, 0 sessions per second in last 30 minutes
Virus caught: 0 total in 1 minute
IPS attacks blocked: 0 total in 1 minute
Uptime: 1 days, 2 hours, 45 minutes

```

The information you're looking for is the average sessions section, in the above output. This example shows that there were 80 sessions in 1 minute, or an average of 3 sessions per second. The values for 10 minutes and 30 minutes allow you to take a longer average for a more reliable value if your FortiGate is working at maximum capacity. The smallest FortiGate can have 1,000 sessions established per second across the unit.

Remember that session setup rate is a global command. If you have multiple VDOMs configured with many sessions in each one, the session setup rate per VDOM will be slower than if there are no VDOMs configured.

Finding object dependencies

An administrator may not be permitted to delete a configuration object if there are other configuration objects that depend on it. This command identifies other objects which depend on, or make reference to, the configuration object in question. If an error is displayed that an object is in use and can't be deleted, this command can help identify the source of the problem.

Additionally, if you have a virtual interface with objects that depend on it, you need to find and remove those dependencies before you delete the interface.

CLI method

When you run multiple VDOMs, you use this command in the global configuration only and it searches for the named object in both the most recently used global and VDOM configurations:

```
diagnose system checkused <path.object.mkey>
```

For example, to verify which objects a security policy with an ID of 1 refers to, enter the following command:

```
diagnose system checkused firewall.policy.policyid 1
```

To check what is referred to by interface `port1`, enter the following command:

```
diagnose system checkused system.interface.name port1
```

To show all dependencies for an interface, enter the following command:

```
diagnose system checkused system.interface.name <interface name>
```

Sample output:

```

entry used by table firewall.address:name '10.98.23.23_host'
entry used by table firewall.address:name 'NAS'
entry used by table firewall.address:name 'all'
entry used by table firewall.address:name 'fortinet.com'

```

```
entry used by table firewall.vip:name 'TORRENT_10.0.0.70:6883'
entry used by table firewall.policy:policyid '21'
entry used by table firewall.policy:policyid '14'
entry used by table firewall.policy:policyid '19'
```

In this example, the interface has dependent objects, including four address objects, one VIP, and three security policies.

GUI method

In the GUI, you can easily check and remove the object dependencies for an interface.

To remove interface object dependencies - GUI

1. Go to **Network > Interfaces**.
The **Ref.** column displays the number of objects that refer to this interface.
2. Select the number in the **Ref.** column for the interface.
A window listing the dependencies appears.
3. Use these detailed entries to locate and remove object references to this interface.
The trash can icon changes from gray when you've removed all object dependencies.
4. Remove the interface by selecting the check box for the interface, and select **Delete**.

Flow trace

To trace the flow of packets through the FortiGate, use the following command:

```
diagnose debug flow trace start
```

Follow packet flow by setting a flow filter, using this command:

```
diagnose debug flow {filter | filter6} <option>
```

If your network uses IPv4, enter `filter`. If your network uses IPv6, enter `filter6`.

One of the following variables replaces `<option>`:

Variable	Description
<code>addr</code>	IPv4 or IPv6 address
<code>clear</code>	clear filter
<code>daddr</code>	destination IPv4 or IPv6 address
<code>dport</code>	destination port
<code>negate</code>	inverse IPv4 or IPv6 filter
<code>port</code>	port

Variable	Description
proto	protocol number
saddr	source address
sport	source port
vd	index of virtual domain; -1 matches all

`diagnose debug flow` output is recorded as event log messages and which are then sent to a FortiCloud or a FortiAnalyzer, if connected. Don't run this command longer than necessary, since it generates significant amounts of data.

To start flow monitoring with a specific number of packets - CLI:

```
diagnose debug flow trace start <N>
```

To stop flow tracing at any time using - CLI:

```
diagnose debug flow trace stop
```

The following example shows the flow trace for a device with an IP address of 203.160.224.97:

```
diagnose debug enable
diagnose debug flow filter addr 203.160.224.97
diagnose debug flow show function-name enable
diagnose debug flow trace start 100
```

Flow trace output example - HTTP

To observe the debug flow trace, connect to the web site at the following address:

```
https://www.fortinet.com
```

Comment: SYN packet received:

```
id=20085 trace_id=209 func=resolve_ip_tuple_fast
line=2700 msg="vd-root received a packet(proto=6,
192.168.3.221:1487->203.160.224.97:80) from port5."
```

SYN sent and a new session is allocated:

```
id=20085 trace_id=209 func=resolve_ip_tuple line=2799
msg="allocate a new session-00000e90"
```

Lookup for next-hop gateway address:

```

id=20085 trace_id=2 msg="enter IPsec ="encrypted, and send to 15.215.225.22 with source
66.236.56.226" tunnel-RemotePhase1"
id=20085 trace_id=2 msgid=20085 trace_id=2 msg="send to 66.236.56.230 via intf-wan1"
```

Packet sniffing and packet capture

When you troubleshoot networks, it helps to look inside the header of the packets. This helps to determine if the packets, route, and destination are all what you expect. Packet capture can also be called a network tap, packet sniffing, or logic analyzing. FortiOS devices can sniff packets using CLI commands or capture packets using the GUI.

Packet sniffing using CLI commands is well-suited for spot checking traffic, but if you have complex filters to enter it can be a lot of work to enter them each time. You can also save the sniffing output. However, you must log to a file and then analyze the file later.

Packet capture in the GUI makes it easy for you to set up multiple filters at once and run only one or two as you need to. You can also use controls to start and stop capturing when you want to. You download packet capture

output to your local computer as a *.pcap file. You must use a third party application, such as Wireshark, to read *.pcap files. This method is useful to send information to Fortinet support to help resolve an issue.

The following table presents a comparison between the two methods:

Features	Packet sniffing	Packet capture
Command location	CLI	GUI
Third party software required	puTTY to log plaintext output	Wireshark, or similar application, to read *.pcap files
Read output in plain text file	yes	no
Read output as *.pcap file using Wireshark, or similar application	no	yes
Easily configure single quick and simple filter	yes	no
Record packet interface	yes	no
Configure complex sniffer filters on multiple interface	no	yes
sniff IPv6	hard	easy
sniff non-IP packets	no	yes
Filter packets by protocol and/or port	easy	easy
Filter packets by source and/or destination address	easy	easy

Packet sniffing

If you're running a constant traffic application, such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the FortiGate is silently dropping packets for reasons such as Reverse Path Forwarding (RPF). RPF, also called anti-spoofing, prevents an IP packet from being forwarded if its source IP doesn't belong to a locally attached subnet (local interface) or isn't part of the routing between the FortiGate and another source (static route, RIP, OSPF, BGP). Note that you can disable RPF by turning on asymmetric routing in the CLI (`config system settings, set asymroute enable`), but this disables stateful inspection on the FortiGate and causes many features to be turned off.

If you configure virtual IP addresses on your FortiGate, it will use those addresses instead of the physical IP addresses. You'll notice this when you're sniffing packets because all the traffic uses the virtual IP addresses. This is due to the ARP update that's sent out when the VIP address is configured.

Before you start sniffing packets on the CLI, you should prepare to capture the output to a file. A large amount of data may scroll by and you won't be able to see it without first saving it to a file. One method is to use a terminal program like puTTY to connect to the FortiGate CLI. Once the packet sniffing count is reached, you can end the session and analyze the output in the file.

The general form of the internal FortiOS packet sniffer command is:

```
diagnose sniffer packet <interface_name> <'filter'> <verbose> <count> <tsformat>
```

To stop the sniffer, type CTRL+C.

<interface_name>	The name of the interface to sniff, such as "port1" or "internal". This can also be "any" to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. "none" indicates no filtering, and all packets are displayed as the other arguments indicate. The filter must be inside single quotes (').
<verbose>	The level of verbosity as one of: 1 - print header of packets 2 - print header and data from IP of packets 3 - print header and data from Ethernet of packets 4 - print header of packets with interface name
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run until you stop it with <CTRL+C>.
<tsformat>	The format of timestamp. <ul style="list-style-type: none"> • a: absolute UTC time, yyyy-mm-dd hh:mm:ss.ms • l: absolute LOCAL time, yyyy-mm-dd hh:mm:ss.ms • otherwise: relative to the start of sniffing, ss.ms

For a simple sniffing example, enter the CLI command `diagnose sniffer packet port1 none 1 3`. This displays the next three packets on the port1 interface using no filtering, and verbose level 1. At this verbosity level, you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets and that 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diagnose sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]

0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

For a more advanced example of packet sniffing, the following commands will report packets on any interface that are traveling between a computer with the host name of “PC1” and a computer with the host name of “PC2”. With verbosity 4 and above, the sniffer trace displays the interface names where traffic enters or leaves the FortiGate unit. Remember to stop the sniffer, type `CTRL+C`.

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2>" 4
```

or

```
FGT# diagnose sniffer packet any "(host <PC1> or host <PC2>) and icmp" 4
```

The following CLI command for a sniffer includes the ARP protocol in the filter which may be useful to troubleshoot a failure in the ARP resolution (for example, PC2 may be down and not responding to the FortiGate ARP requests).

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2> or arp" 4
```

Packet capture

Packet capture tells you what is happening on the network at a low level. This can be very useful for troubleshooting problems, such as:

- Finding missing traffic
- Seeing if sessions are setting up properly
- Locating ARP problems such as broadcast storm sources and causes
- Confirming which address a computer is using on the network, if they have multiple addresses or are on multiple networks
- Confirming routing is working as you expect
- Connecting wireless clients
- Missing PING packets
- A particular type of packet is having problems, such as UDP, which is commonly used for streaming video

If you're running a constant traffic application such as ping, packet capture can tell you if the traffic is reaching the destination, how the port enters and exits the FortiGate, if the ARP resolution is correct, and if the traffic is returning to the source as expected. You can also use packet switching to verify that NAT or other configuration is translating addresses or routing traffic the way that you want it to.

Before you start capturing packets, you need to have a good idea of what you're looking for. Capture is used to confirm or deny your ideas about what's happening on the network. If you try capture without a plan to narrow your search, you can end up with too much data to effectively analyze. On the other hand, you need to capture enough packets to really understand all of the patterns and behavior that you're examining.

To use packet capture, the FortiGate must have a disk. You can enable the `capture-packet` in the firewall policy, using the following CLI commands:

```
config firewall policy
  edit <id>
    set capture-packet enable
  end
```

To configure packet capture filters, go to **Network > Packet Capture**.

When you add a packet capture filter, enter the following information and select **OK**.

Interface	Select the interface to sniff from the drop-down menu. You must select one interface. You can't change the interface without deleting the filter and creating a new one, unlike the other fields.
Max Packets to Save	Enter the number of packets to capture before the filter stops. This number can't be zero. You can halt the capturing before this number is reached.
Enable Filters	Select this option to specify filter fields
Host(s)	Enter the IP address of one or more hosts Separate multiple hosts with commas. To enter a range, use a dash without spaces, for example 172.16.1.5-172.16.1.15, or enter a subnet.
Port(s)	Enter one or more ports to capture on the selected interface. Separate multiple ports with commas. To enter a range, use a dash without spaces, for example 88-90
VLAN(s)	Enter one or more VLANs (if any). Separate multiple VLANs with commas.
Protocol	Enter one or more protocols. Separate multiple protocols with commas. To enter a range, use a dash without spaces, for example 1-6, 17, 21-25.
Include IPv6 Packets	Select this option if you're troubleshooting IPv6 networking, or if your network uses IPv6. Otherwise, leave it disabled.
Include Non-IP Packets	The protocols in the list are all IP based except for ICMP (ping). To capture non-IP based packets, select this feature. Examples of non-IP packets include IPsec, IGMP, ARP, and ICMP.

If you select a filter, you have the option to start and stop packet capture in the edit window, or download the captured packets. You can also see the filter status and the number of packets captured.

You can select the filter and start capturing packets. When the filter is running, the number of captured packets increases until it reaches the **Max Packet Count** or you stop it. When the filter is running, you can't download the output file.

When the packet capture is complete, you can download the *.pcap file. You must use a third party application, such as Wireshark, to read *.pcap files. This tool provides you with extensive analytics and the full contents of the packets that were captured.

To start, stop, or resume packet capture, use the symbols on the screen. These symbols are the same as those used for audio or video playback. Hover over the symbol to reveal explanatory text. Similarly, to download the *.pcap file, use the download symbol on the screen.

NPU-based interfaces

Many Fortinet products contain network processors, such as NP1, NP2, NP4, and NP6, which means that offloading requirements vary depending on the model.

When you use the NPU-based interfaces, you can see only the initial session setup will be seen using the `diagnose debug flow` command. If the session is correctly programmed into the ASIC (fastpath), the `diagnose debug flow` command won't detect the packets that arrive at the CPU. If the NPU functionality is disabled, the CPU detects all the packets. However, you should only this for troubleshooting purposes.

First, obtain the NP4 or NP6 ID and the port numbers, using the following command:

```
diagnose npu {np4|npu6}list
```

Sample output:

```
ID Model Slot Interface
0 On-board port1 fabric1 fabric3 fabric5
1 On-board fabric2 port2 base2 fabric4
```

Run the following commands:

```
diagnose npu {np4|npu6}fastpath disable <dev_id>
```

(where `dev_id` is the NP4 or NP6 number)

Then, run this command:

```
diagnose npu {np4|npu6}fastpath-sniffer enable port1
```

Sample output:

```
NP4 Fast Path Sniffer on port1 enabled
```

This causes traffic on **port1** of the network processor to be sent to the CPU. this means that you can take a standard sniffer trace and use other diagnose commands, if it's a standard CPU-driven port.

These commands only apply to the newer NP4 and NP6 interfaces.

Debug command

Debug output provides continuous, real-time event information and continues until you stop it or reboot the unit. Debug output can affect system performance and is continually generated even though output might not be displayed in the CLI console.

Debug information that's displayed in the console scrolls in the console display and may prevent you from entering CLI commands, such as, the command to disable the debug display. To turn off debug output as the display scrolls by, press the **↑** key to recall the recent `diagnose debug` command, press backspace, and type "0", and **Enter**.

To enable debug output display, use the following command:

```
diagnose debug enable
```

Once you enable debug output display, specify the debug information that you require using the following command:

```
diagnose debug <option> <level>
```

Debug command options include the following:

<code>enable</code>	Enable debug output
<code>disable</code>	Disable debug output
<code>info</code>	Show active debug level settings
<code>reset</code>	Reset all debug level to default
<code>report</code>	Report for tech support
<code>crashlog</code>	Crash log info
<code>config-error-log</code>	Configure error log info
<code>sql-log-error</code>	SQL log database error info
<code>application</code>	application
<code>kernel</code>	kernel
<code>remote-extender</code>	remote-extender
<code>cli</code>	Debug CLI
<code>cmdb-trace</code>	Trace CLI
<code>rating</code>	Display rating info
<code>authd</code>	Authentication daemon
<code>fsso-polling</code>	FSSO active directory poll module
<code>flow</code>	Trace packet flow in kernel
<code>urlfilter</code>	urlfilter
<code>admin</code>	Admin user

You can set the debug level at the end of the command. For example, typical values are 2 and 3, like in the following commands:

```
diagnose debug application DHCPDS 2
diagnose debug application spamfilter 2
```

Fortinet support will advise you about which debugging level you should use.

You can enable timestamps to the debug output, using the following command:

```
diagnose debug console timestamp enable
```

When you finish examining the debug output, disable it, using the following command:

```
diagnose debug disable
```

Debug output example

This example shows the IKE negotiation for a secure logging connection from a FortiGate to a FortiAnalyzer.

```
diagnose debug reset
diagnose vpn ike log-filter src-addr4 192.168.11.2
diagnose debug enable
```

Sample output:

```
FGh_FtiLog1: IPsec SA connect 0 192.168.11.2->192.168.10.201:500, natt_mode=0 rekey=0
phase2=FGh_FtiLog1
FGh_FtiLog1: using existing connection, dpd_fail=0
FGh_FtiLog1: found phase2 FGh_FtiLog1
FGh_FtiLog1: IPsec SA connect 0 192.168.11.2 -> 192.168.10.201:500 negotiating
FGh_FtiLog1: overriding selector 225.30.5.8 with 192.168.11.2
FGh_FtiLog1: initiator quick-mode set pfs=1536...
FGh_FtiLog1: try to negotiate with 1800 life seconds.
FGh_FtiLog1: initiate an SA with selectors: 192.168.11.2/0.0.0.0->192.168.10.201,
ports=0/0, protocol=0/0
Send IKE Packet(quick_outI1):192.168.11.2:500(if0) -> 192.168.10.201:500, len=348
Initiator: sent 192.168.10.201 quick mode message #1 (OK)
FGh_FtiLog1: set retransmit: st=168, timeout=6.
```

In this example:

192.168.11.2->192.168.10.201:500	Source and destination gateway IP address
dpd_fail=0	Found existing Phase 1
pfs=1536...	Create new Phase 2 tunnel

The execute tac report command

`exec tac report` is an execute command that runs an exhaustive series of diagnostic commands. It runs commands that are only needed if you're using certain features, such as HA, VPN tunnels, or a modem. The report takes a few minutes to finish because of the amount of output that's generated. If you're logging CLI output to a file, you can run this command to familiarize yourself with the diagnostic commands.

When you contact [Fortinet Support](#), you may be asked to use the output from this CLI command to provide information about your FortiGate and its current state.

Other commands

ARP table

To view the ARP cache, use the following command:

```
get system arp
```

To view the ARP cache in the system, use the following command:

```
diagnose ip arp list
```

Sample output:

```
index=14 ifname=internal 224.0.0.5 01:00:5e:00:00:05 state=00000040 use=72203
confirm=78203 update=72203 ref=1
index=13 ifname=dmz 192.168.3.100 state=00000020 use=1843 confirm=650179 update=644179
ref=2 ? VIP
index=13 ifname=dmz 192.168.3.109 02:09:0f:78:69:ff state=00000004 use=71743 confirm=75743
update=75743 ref=1
index=14 ifname=internal 192.168.11.56 00:1c:23:10:f8:20 state=00000004 use=10532
confirm=10532 update=12658 ref=4
```

To remove the ARP cache, use the following command:

```
execute clear system arp table
```

To remove a single ARP entry, use the following command:

```
diagnose ip arp delete <interface name> <IP address>
```

To add static ARP entries, use the following command:

```
config system arp-table
```

Time and date settings

Check time and date settings for log message timestamp synchronization (the Fortinet support group may request this) and for certificates that have a time requirement to check for validity. Use the following commands:

```
execute time
current time is: 12:40:48
last ntp sync:Thu Mar 16 12:00:21 2006
execute date
current date is: 2006-03-16
```

To force synchronization with an NTP server, use the following command:

```
config system ntp
set ntpsync {enable|disable}
end
```

If all devices have the same time, it helps to correlate log entries from different devices.

IP address

There may be times when you want to verify that the IP addresses assigned to the FortiGate interfaces are what you expect them to be. This is easily accomplished from the CLI, using the following command:

```
diagnose ip address list
```

The output from this command lists the IP address and mask (if available), the `index` of the interface (a type of ID number), and the `devname` (the interface name). While physical interface names are set, virtual interface names can vary. A good way to use this command is to list all of the virtual interface names. Listing all the virtual interface names is a good use of this command. For `vsys_ha` and `vsys_fgfm`, the IP addresses are the local host, which are virtual interfaces that are used internally.

```
# diagnose ip address list
```

```

IP=10.31.101.100->10.31.101.100/255.255.255.0 index=3 devname=internal
IP=172.20.120.122->172.20.120.122/255.255.255.0 index=5 devname=wan1
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=8 devname=root
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=11 devname=vsys_ha
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=13 devname=vsys_fgfm

```

FortiOS ports

There are 65,535 ports in TCP and UDP stacks that applications can use when they communicate with each other. Many of these ports are commonly known to be associated with specific applications or protocols. These ports can be useful when you troubleshoot your network.

Use the following ports when you troubleshoot your FortiGate:

Port	Functionality
UDP 53	DNS lookup, RBL lookup
UDP 53 or UDP 8888	FortiGuard Antispam or Web Filtering rating lookup
UDP 53 (default) or UDP 8888 and UDP 1027 or UDP 1031	FDN server list - source and destination port numbers vary by originating or reply traffic
UDP 123	NTP synchronization
UDP 162	SNMP traps
UDP 514	SYSLOG - All FortiOS versions can use syslog to send log messages to remote syslog servers
TCP 22	Configuration backup to FortiManager unit or FortiGuard Analysis and Management Service
TCP 25	SMTP alert email, encrypted virus sample auto-submit
TCP 389 or TCP 636	LDAP or PKI authentication
TCP 443	FortiGuard Antivirus or IPS update - When you request updates from a FortiManager, instead of directly from the FDN, you must reconfigure this port as TCP 8890
TCP 443	FortiGuard Analysis and Management Service
TCP 514	FortiGuard Analysis and Management Service log transmission (OFTP)
TCP 514	SSL Management Tunnel to FortiGuard Analysis and Management Service
TCP 514	Quarantine, remote access to logs and reports on a FortiAnalyzer unit, device registration with FortiAnalyzer units (OFTP)
TCP 1812	RADIUS authentication

Port	Functionality
TCP 8000 and TCP 8002	FSSO
TCP 10151	FortiGuard Analysis and Management Service contract validation

FortiAnalyzer and FortiManager ports

If you have a FortiAnalyzer or FortiManager on your network, you may need to use the following ports to troubleshoot network traffic:

Port	Functionality
UDP 53	DNS lookup
UDP 123	NTP synchronization
UDP 137-138	Windows share
UDP 162	SNMP traps
UDP 514	Syslog, log forwarding
TCP 21 or TCP 22	Log and report upload
TCP 25	SMTP alert email
TCP 389 or TCP 636	User name LDAP queries for reports
TCP 443	RVS update
TCP 1812	RADIUS authentication
TCP 3000	Log aggregation client

FortiGuard troubleshooting

The FortiGuard service provides updates to AntiVirus (AV), Antispam (AS), Intrusion Protection Services (IPS), Webfiltering (WF), and more. The FortiGuard Distribution System (FDS) consists of a number of servers across the world that provide updates to your FortiGate unit. Problems can occur with the connection to FDS and its configuration on your local FortiGate unit. Some of the more common troubleshooting methods are listed here, including:

- [Troubleshooting process for FortiGuard updates](#)
- [FortiGuard server settings](#)

Troubleshooting process for FortiGuard updates

The following process shows the logical steps that you should take when you troubleshoot problems with FortiGuard update:

1. Does the device have a valid licence that includes these services?

Each device requires a valid FortiGuard license to access updates for some or all of these services. You can verify the status of the support contract for your devices at the [Fortinet Support](#) website.

2. If the device is part of a high availability (HA) cluster, do all members of the cluster have the same level of support?

As with the previous step, you can verify the status of the support contract for all of the devices in your HA cluster at the [Fortinet Support](#) website.

3. Are services enabled on the device?

To see the FortiGuard information and status for a device, in the GUI, go to **System > FortiGuard**. On that page, you can verify the status of each component, and enable each service. If you encounter problems, see the [FortiGuard](#) discussion in the [Fortinet Communication Ports and Protocols](#) chapter of the FortiOS Handbook.

4. Can the device communicate with FortiGuard servers?

Go to System > FortiGuard in the GUI and try to update AV and IPS, or test the availability of WF and AS default and alternate ports. If you encounter problems, see the [FortiGuard](#) discussion in the [Fortinet Communication Ports and Protocols](#) chapter of the FortiOS Handbook.

5. Is there proper routing to reach the FortiGuard servers?

Ensure there is a static or dynamic route that allows your FortiGate to reach the FortiGuard servers. Usually a generic default route to the internet is enough, but you may need to verify this if your network is complex.

6. Are there issues with DNS?

An easy way to test this is to attempt a traceroute from behind the FortiGate to an external network using the Fully Qualified Domain Name (FQDN) for a location. If the traceroute FQDN name doesn't resolve, you have general DNS problems.

7. Is there anything upstream that might be blocking FortiGuard traffic, either on the network or ISP side?

Many firewalls block all ports, by default, and ISPs often block ports that are low. There may be a firewall between the FortiGate and the FortiGuard servers that's blocking the traffic. FortiGuard uses port 53, by default, so if that port is blocked you need to either open a hole for it or change the port it is using.

8. Is there an issue with source ports?

It's possible that ports that the FortiGate uses to contact FortiGuard are being changed before they reach FortiGuard or on the return trip before they reach the FortiGate. A possible solution for this is to use a fixed-port at NAT'd firewalls to ensure the port remains the same. You can use packet sniffing to find more information about what's happening with ports.

9. Are there security policies that include antivirus?

If none of the security policies include antivirus, the antivirus database won't be updated. If antivirus is included, only the database type that's used will be updated.

FortiGuard server settings

Your local FortiGate connects to remote FortiGuard servers to get updates to FortiGuard information, such as new viruses that may have been found or other new threats. This section shows ways that you can display FortiGuard server information on your FortiGate, and how you can use that information and update it to fix potential problems.

Displaying the server list

The `get webfilter status` or `diagnose debug rating` command shows the list of FDS servers that the FortiGate uses to send web filtering requests. Rating requests are only sent to the server at the top of the list in normal operation. Each server is probed for Round Trip Time (RTT) every two minutes.

Optionally, you can add a refresh rate to the end of this command to determine how often the server list is refreshed.

Rating may not be enabled on your FortiGate.

To show the list of servers a FortiGate uses to send web filtering requests - CLI

```
get webfilter status
```

Sample output:

```
Locale : english
License : Contract
Expiration : Thu Oct 9 02:00:00 2011
== Server List (Mon Feb 18 12:55:48 2008) ==
```

IP	Weight	RTT	Flags	TZ	Packets	CurrLost	TotalLost
a.b.c.d	0	1	DI	2	1926879	0	11176
10.1.101.1	10	329		1	10263	0	633
10.2.102.2	20	169		0	16105	0	80
10.3.103.3	20	182		0	6741	0	776
10.4.104.4	20	184		0	5249	0	987
10.5.105.5	25	181		0	12072	0	178

Output details

The server list includes the IP addresses of alternate servers if the first entry can't be reached. In this example, the IP addresses are not public addresses.

The following flags in `get webfilter status` indicate the server status:

Flag	Description
D	The server was found through the DNS lookup of the hostname. If the hostname returns more than one IP address, all of them are flagged with D and are used first for INIT requests before falling back to the other servers.
I	The server to which the last INIT request was sent
F	The server hasn't responded to requests and is considered to have failed

Flag	Description
T	The server is currently being timed
S	Rating requests can be sent to the server The flag is set for a server only in two cases: <ol style="list-style-type: none">1. The server exists in the servers list received from the FortiManager or any other INIT server.2. The server list received from the FortiManager is empty so the FortiManager is the only server that the FortiGate knows and it should be used as the rating server.

Sorting the server list

The server list is sorted first by weight. The server with the smallest RTT appears at the top of the list, regardless of weight. When a packet is lost (there has been no response in 2 seconds), it's re-sent to the next server in the list. Therefore, the top position in the list is selected based on RTT, while the other positions are based on weight.

Calculating weight

The weight for each server increases with failed packets and decreases with successful packets. To lower the possibility of using a remote server, the weight isn't allowed to dip below a base weight. The base weight is calculated as the difference in hours between the FortiGate and the server multiplied by 10. The farther away the server is, the higher its base weight is and the lower it appears in the list.

Troubleshooting tips

The following tips present common causes of problems.

How to check hardware connections

- Are all of the cables and interfaces connected properly?
- Is the LED for the interface green?

How to check FortiOS network settings

- If you're having problems connecting to the management interface, is your protocol enabled on the interface for administrative access?
- Does the interface have an IP address?

How to check CPU and memory resources

- Is the CPU running at almost 100 percent usage?
- Is your FortiGate running low on memory?

How to check modem status

- Is the modem connected?
- Are there PPP issues?

How to run ping and traceroute

- Is the FortiGate experiencing complete packet loss?

How to check the logs

- Do you need to identify a problem?

How to verify the contents of the routing table (in NAT mode)

- Are there routes in the routing table for default and static routes?
- Do all connected subnets have a route in the routing table?
- Does a route have a higher priority than it should?

How to verify the correct route is being used

- Is the traffic routed correctly?

How to verify the correct firewall policy is being used

- Is the correct firewall policy applied to the expected traffic?

How to check the bridging information in transparent mode

- Are you having problems in transparent mode?

How to check number of sessions used by UTM proxy

- Have you reached the maximum number of sessions for a protocol?
- Are new sessions failing to start for a certain protocol?

How to examine the firewall session list

- Are there active firewall sessions?

[How to check wireless information](#)

- Is the wireless network working properly?

[How to verify FortiGuard connectivity](#)

- Is the FortiGate communicating properly with FortiGuard?

[How to perform a sniffer trace \(CLI and packet capture\)](#)

- Is traffic entering the FortiGate? Does the traffic arrive on the expected interface?
- Is the ARP resolution correct for the next-hop destination?
- Is the traffic exiting the FortiGate to the destination as expected?
- Is the FortiGate sending traffic back to the originator?

[How to debug the packet flow](#)

- Is traffic entering or leaving the FortiGate as expected?

How to check hardware connections

If there's no traffic flowing from the FortiGate, you may have a hardware problem.

To check hardware connections:

- Ensure network cables are plugged into the interfaces.
- Verify that the LED connection lights for the network cables are the right color (usually green).
- If the cable or its connector are damaged, change the cable. You should also change the cable if you're not sure about the type or quality of the cable, such as straight through or crossover, or if you see exposed wires at the connector.
- Connect the FortiGate to different hardware.
- Ensure the link status is set to **Up** for the interface (see **Network > Interfaces**). The link status is based on the physical connection and can't be set in FortiOS.

If any of these solve the problem, it was a hardware connection problem. You should still perform some basic software connectivity tests to ensure complete connectivity. The interface might also be disabled, or its **Administrative Status** might be set to **Down**.

To enable an interface - GUI

1. Go to **Network > Interfaces**.
2. Select and edit the interface to enable, such as **port1**.
3. Find **Administrative Status** at the bottom of the screen, and select **Up**.
4. Select **Apply**.

To enable an interface - CLI

```
config system interface
  edit port1
    set status up
  next
end
```

How to check FortiOS network settings

You can manage FortiOS network settings in the GUI and the CLI. The following information includes troubleshooting and best practice information. The network settings include:

- [Interface settings](#)
- [DNS settings](#)
- [DHCP server settings](#)

Interface settings

If you can access the FortiGate with the management cable only, the first step is to display the interface settings. To display the settings for the internal interface, use the following CLI command:

```
FGT# show system interface <interface_name>
```

For a complete listing of all the possible interface settings, use the following CLI command:

```
config system interface
  edit <interface_name>
  get
end
```

Check the interface settings to ensure that they aren't preventing traffic. Check the following items (only the GUI terms are shown, CLI terms may vary):

Setting	Description
Link Status	Down until a valid cable is plugged into this interface, then it will be Up . The Link Status is shown physically by the connection LED for the interface. If the LED is green, the connection is good. If Link Status is Down , the interface doesn't work. Link Status is also displayed on the Network > Interfaces screen, by default.
Addressing mode	Don't use DHCP if you don't have a DHCP server. You won't be able to log in to an interface in DHCP mode as it won't have an IP address.
IP/Network Mask	An interface needs an IP address to be able to connect to other devices. Ensure there is a valid IP address in this field. The one exception is if DHCP is enabled for this interface to get its IP address from an external DHCP server.
IPv6 address	The same protocol must be used by both ends to complete the connection. Ensure both this interface and the remote connection are both using IPv4 or both using IPv6 addressing.
Administrative access	If no protocols are selected, you will have to use the local management cable to connect to the unit. If you're using IPv6, configure the IPv6 administrative access protocols.
Administrative status	Set to Up or the interface won't work.

DNS settings

You can trace many networking problems back to DNS issues. Check the following items:

- Are there values for both primary and secondary entries?
- Is the local domain name correct?
- Are you using IPv6 addressing? If so, are the IPv6 DNS settings correct?
- Are you using Dynamic DNS (DDNS)? If so, is it using the correct server, credentials, and interface?
- Can you contact both DNS servers to verify the servers are operational?
- If an interface addressing mode is set to DHCP and is set to override the internal DNS, is that interface receiving a valid DNS entry from the DHCP server? Is it a reasonable address and can it be contacted to verify it's operational?
- Are there any DENY security policies that need to allow DNS?
- Can any internal device perform a successful traceroute to a location using the FQDN?

DHCP server settings

DHCP servers are common on internal and wireless networks. If the DHCP server isn't configured correctly, it can cause problems. Check the following items:

- Is the DHCP server entry set to **Relay**? If so, verify there is another DHCP server to which requests can be relayed. Otherwise, it should be set to **Server**.
- Is the DHCP server enabled?
- Does the DHCP server use a valid IP address range? Are other devices using the addresses? If one or more devices are using IP addresses in this range, you can use the IP reservation feature to ensure the DHCP server doesn't use these addresses.
- Is there a gateway entry? If not, add a gateway entry to ensure that the server's clients have a default route.
- Is the system DNS setting being used? A best practice is to avoid confusion by using the system DNS whenever possible. However, you can specify up to three custom DNS servers, and you should use all three entries for redundancy.

There are some situations, such as a new wireless interface, or during the initial FortiGate configuration, where interfaces override the system DNS entries. When this happens, it often shows up as intermittent Internet connectivity. To fix the problem, go to **Network > DNS** and enable **Use FortiGuard Servers**.

How to check CPU and memory resources

System resources are shared and a number of processes run simultaneously on the FortiGate unit.

The **Resource** widgets for **CPU** and **Memory** on the **Dashboard** provide a quick way to monitor usage.

To use the CLI to check the system resources on your FortiGate unit, run the following command:

```
FGT# get system performance status
```

This command provides a quick and easy snapshot of the FortiGate.

The first line of output shows the CPU usage by category. A FortiGate that is doing nothing looks like the following example:

```
CPU states: 0% user 0% system 0% nice 100% idle
```

However, if your network is running slow you might see something looks like the following example:

```
CPU states: 1% user 98% system 0% nice 1% idle
```

This line shows that all the CPU is used up by system processes. Normally this shouldn't happen since it shows that the FortiGate is overloaded for some reason. If you see this overloading, you should investigate further because it's possible a process, such as `scanunitid`, is using all the resources to scan traffic, in which case you need to reduce the amount of traffic that's being scanned by blocking unwanted protocols, configuring more security policies to limit scanning to certain protocols, or similar actions. It's also possible that a hacker has gained access to your network and is overloading it with malicious activity, such as running a spam server or using zombie PCs to attack other networks on the Internet. You can use the `get system performance top` CLI command to get more information about the CPU. This command shows all of the top processes that are running on the FortiGate (the names are on the left) and their CPU usage. If a process is using most of the CPU cycles, investigate it to determine whether the activity is normal.

The second line of output from the `get system performance status` command shows the memory usage. Memory usage shouldn't exceed 90%. If memory is too full, some processes won't be able to function properly. For example, if the system is running low on memory, antivirus scanning enters into failopen mode where it drops connections or bypasses the antivirus system.

The other lines of output, such as average network usage, average session setup rate, viruses caught, and IPS attacks blocked, can also help you determine why system resource usage is high. For example, if network usage is high it results in high traffic processing on the FortiGate, or if the session setup rate is very low (or zero) the proxy may be overloaded and unable to do its job.

How to troubleshoot high memory usage

As with any system, a FortiGate has limited hardware resources, such as memory, and all processes running on the FortiGate share the memory. Each process uses more or less memory, depending on its workload. For example, a process usually uses more memory in high traffic situations. If some processes use all of the available memory, other processes won't be able to run.

When high memory usage occurs, the services may freeze up, connections may be lost, or new connections may be refused.

If you see high memory usage in the **Memory** widget, the FortiGate may be handling high traffic volumes. Alternatively, the FortiGate may have with connection pool limits that are affecting a single proxy. If the FortiGate receives large volumes of traffic on a specific proxy, the unit may exceed the connection pool limit. If the number of free connections within a proxy connection pool reaches zero, issues may occur.

Use the following CLI command, which uses the antivirus failopen feature:

```
config system global
    set av-failopen idledrop
end
```

If you set `av-failopen` to `idledrop`, the FortiGate drops connections based on the clients that have the most open connections. This helps you determine the behavior of the FortiGate antivirus system if it becomes overloaded in high traffic.

Use the following CLI command, which shows information about current memory usage:

```
diagnose hardware sysinfo memory
```

Sample output:

```

total: used: free: shared: buffers: cached: shm:
Mem: 2074185728 756936704 1317249024 0 20701184 194555904 161046528

SwapFree:      0 kB

```

How to troubleshoot high CPU usage

If you deploy too many FortiOS features at the same time, you can overextend the CPU resources on a FortiGate. When this occurs, the FortiGate undergoes connection-related problems.

Some examples of CPU intensive features are:

- VPN high-level encryption
- Intensive scanning of all traffic
- Logging all traffic and packets
- Dashboard widgets that frequently perform data updates

1. Determine the current level of CPU usage.

There are two ways to do this. The simplest is to look at the **CPU** widget on the **Dashboard** in the FortiGate GUI. The real-time CPU usage is displayed for different timeframes. The second method provides precise usage values both for overall usage and for specific processes. To use it, run the `diagnose system top` CLI command.

Sample output:

```

Run Time: 86 days, 0 hours and 10 minutes
OU, ON, OS, 100I, OWA, OHI, OSI, OST; 3040T, 2437F
bcm.user 93 S < 3.1 0.4
httpsd 18922 S 1.5 0.5
httpsd 19150 S 0.3 0.5
newcli 20195 R 0.1 0.1
cmdbsvr 115 S 0.0 0.8
pyfcgid 20107 S 0.0 0.6
forticron 146 S 0.0 0.5
httpsd 139 S 0.0 0.5
cw_acd 166 S 0.0 0.5
miglogd 136 S 0.0 0.5
pyfcgid 20110 S 0.0 0.4
pyfcgid 20111 S 0.0 0.4
pyfcgid 20109 S 0.0 0.4

```

```

httpsd 20192 S 0.0 0.4
miglogd 174 S 0.0 0.4
miglogd 175 S 0.0 0.4
fgfmd 165 S 0.0 0.3
newcli 20191 S 0.0 0.3
initXXXXXXXXXX 1 S 0.0 0.3
httpsd 184 s 0.0 0.3

```

The codes displayed on the second output line are explained in the following table:

Code	Description
U	the percentage of user space applications that are currently using the CPU
N	the percentage of time that the CPU spent on low priority processes since the last shutdown
S	the percentage of system processes (or kernel processes) that are using the CPU
I	the percentage of idle CPU resources
WA	the percentage of time that the CPU spent waiting on IO peripherals since the last shutdown
HI	the percentage of time that the CPU spent handling hardware interrupt routines since the last shutdown
SI	the percentage of time that the CPU spent handling software interrupt routines since the last shutdown
ST	or steal time, is the percentage of time that a virtual CPU waits for the physical CPU when the hypervisor is servicing another virtual processor
T	is the total FortiOS system memory, in MB
F	is free memory, in MB

Each additional line of the command output displays information for specific processes running on the FortiGate unit. For example, the third line of the output is:

```
newcli 20195 R 0.1 0.1
```

The items in the third line of output are explained in the following table:

Item	Description
newcli	the process name Other process names can include <code>ipsengine</code> , <code>sshd</code> , <code>cmdbsrv</code> , <code>httpsd</code> , <code>scanunitd</code> , and <code>miglogd</code> . Duplicate process names indicate that separate instances of that process that are running.
20195	the process ID, which can be any number
R	current state of the process. The process state can be: <ul style="list-style-type: none"> • R - running • S - sleep • Z - zombie • D - disk sleep
0.1	the percentage of CPU capacity that the process is using CPU usage can range from 0.0 for a process that is sleeping to higher values for a process that's taking a lot of CPU time
0.1	the amount of memory that the process is using Memory usage can range from 0.1 to 5.5 and higher.

When `diagnose system top` is running, enter the following single-key commands:

- `q` to quit and return to the normal CLI prompt.
- `p` to sort the processes by the amount of CPU that the processes are using.
- `m` to sort the processes by the amount of memory that the processes are using.

The processes listed are the top processes that are running not all of the processes. For example, if there are 20 processes listed, they are the top 20 processes, sorted by either CPU or memory usage. You can configure the number of processes displayed, using the following CLI command:

```
diagnose system top <integer_seconds> <integer_maximum_lines>
```

Where:

- `<integer_seconds>` is the delay in seconds (default is 5)
 - `<integer_maximum_lines>` is the maximum number of lines (or processes) to list (default is 20)
2. Determine what features are using most of the CPU resources.
There is a command in the CLI that shows the top few processes that are currently running and use the most CPU resources. The `get system performance top` command shows a table of information. The second column from the right shows CPU usage by percentage. If the top few entries are using most of the CPU, note which processes they are and try to reduce their CPU load.

Some examples of processes you'll see include:

- `ipsengine` — the IPS engine that scans traffic for intrusions
- `scanunitd` — antivirus scanner
- `httpsd` — secure HTTP
- `iked` — internet key exchange (IKE) in use with IPsec VPN tunnels
- `newcli` — active whenever you're accessing the CLI
- `sshd` — there are active secure socket connections
- `cmdbsrv` — the command database server application

Go to the features that are at the top of the list and look for evidence of them overusing the CPU. Generally, the monitor for a feature is a good place to start.

3. Check for unnecessary CPU “wasters”.

These are some best practices that will reduce your CPU usage, even if the FortiGate isn't experiencing high CPU usage. Note that if the following information instructs you to turn off a feature that you require, disregard that part of the instructions.

- Use hardware acceleration wherever possible to offload tasks from the CPU. Offloading tasks, such as encryption, frees up the CPU for other tasks.
- Avoid the use of GUI widgets that require computing cycles, such as the Top Sessions widget. These widgets constantly poll the system for information, which uses CPU and other resources.
- Schedule antivirus, IPS, and firmware updates during off peak hours. These updates don't usually consume CPU resources but they can disrupt normal operation.
- Check the log levels and which events are being logged. This is the severity of the messages that are recorded. Consider going up one level to reduce the amount of logging. Also, if there are events you don't need to monitor, remove them from the list.
- Log to FortiCloud instead of logging to memory or disk. Logging to memory quickly uses up resources and logging to local disk impacts overall performance and reduces the lifetime of the unit. Fortinet recommends that you log to FortiCloud because it doesn't use much CPU.
- If the disk is almost full, transfer the logs or data off the disk to free up space. When a disk is almost full it consumes a lot of resources to find free space and organize the files.
- If packet logging is enabled on the FortiGate, consider disabling it. When packet logging is enable, it records every packet that comes through that policy.
- Halt all sniffers and traces.
- Ensure the FortiGate isn't scanning traffic twice. If traffic enters the FortiGate on one interface, goes out another, and then comes back in again, that traffic doesn't need to be rescanned. Doing so is a waste of resources. However, ensure that traffic truly is being scanned once.
- Reduce the session timers to close unused sessions faster. Enter the following CLI commands, which reduce the default values. Note that, by default, the system adds 10 seconds to `tcp-timewait`.

```
config system global
    set tcp-halfclose-timer 30
    set tcp-halfopen-timer 30
    set tcp-timewait-timer 0
    set udp-idle-timer 60
end
```

- In **System > Feature Visibility**, only enable features that you need.

4. When CPU usage is under control, use SNMP to monitor CPU usage. Alternatively, use logging to record CPU and memory usage every 5 minutes.

Once things are back to normal, you should set up a warning system that sends you alerts when CPU resources

are used excessively. A common method to do this is using SNMP. SNMP monitors many values in FortiOS and allows you to set high water marks that generate events. You run an application on your computer to watch for and record these events. Go to **System > SNMP** to enable and configure an SNMP community. If this method is too complicated, you can use the **System Resources** widget to record CPU usage. However, this method only records problems as they happen and won't send you alerts for problems.

How to check modem status

If the modem doesn't work properly or a FortiGate doesn't detect the modem, you can use the following diagnostic command to help you troubleshoot issues with the modem:

```
diagnose system modem {cmd | com | detect | history | external-modem | query| reset}
```

You should always run the following diagnose command after you insert the USB modem into the FortiGate:

```
diagnose system modem detect
```

You can view the modem configuration, using the `get system modem` command. You can also view the modem's vendor and the custom product identification number from the information output from the `get system modem` command.

When there are connectivity issues, use the following to help you resolve them:

- `diagnose debug enable` – activates the debug on the console
- `diagnose debug application modemd` – dumps communication between the modem and the unit.
- `diagnose debug application ppp` – dumps the PPP negotiating messages.
- `execute modem dial` – displays modem debug output.

The modem diagnose output shouldn't contain errors on the way to initializing. You should also verify the number that is used to dial into your ISP.

How to run ping and traceroute

Ping and traceroute are useful tools in network troubleshooting. Alone, either one can determine network connectivity between two points. However, ping can be used to generate simple network traffic that you can view using `diagnose` commands on the FortiGate. This combination can be very powerful when you're trying to locate network problems.

In addition to their normal uses, ping and traceroute can tell you if your computer or network device has access to a domain name server (DNS). While both tools can use IP addresses alone, they can also use domain names for devices. This is an added troubleshooting feature that can be useful in determining why particular services, such as email or web browsing, may not work properly.

If ping doesn't work, it may be disabled on at least one of the interface settings, and security policies for that interface.

Both ping and traceroute require particular ports to be open on firewalls, or else they can't function. Since you typically use these tools to troubleshoot, you can allow them in the security policies and on interfaces only when you need them. Otherwise, keep the ports disabled for added security.

Ping

The ping command sends a very small packet to a destination, and waits for a response. The response has a timer that expires when the destination is unreachable.

Ping is part of layer 3 on the OSI Networking Model. Ping sends Internet Control Message Protocol (ICMP) “echo request” packets to the destination, and listens for “echo response” packets in reply. However, many public networks block ICMP packets because ping can be used in a denial of service (DoS) attack (such as Ping of Death or a smurf attack), or by an attacker to find active locations on the network. By default, FortiGate units have ping enabled while broadcast-forward is disabled on the external interface.

What ping can tell you

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is some packet loss detected, you should investigate the following:

- Possible ECMP, split horizon, or network loops.
- Cabling, to ensure no loose connections.
- Verify which security policy was used (use the packet count column on the **Policy & Objects > IPv4 Policy** or **Policy & Objects > IPv6 Policy** page).

If there is total packet loss, you should investigate the following:

- **Hardware:** ensure cabling is correct, and all equipment between the two locations is accounted for.
- **Addresses and routes:** ensure all IP addresses and routing information along the route is configured as expected.
- **Firewalls:** ensure all firewalls, including FortiGate security policies allow PING to pass through.

How to use ping

Ping syntax is the same for nearly every type of system on a network.

To ping from a FortiGate unit

1. Connect to the CLI either through telnet or through the CLI widget on the **Dashboard**.
2. Enter `exec ping 10.11.101.101` to send 5 ping packets to the destination IP address. There are no options for this command.

Sample output:

```
Head_Office_620b # exec ping 10.11.101.101
PING 10.11.101.101 (10.11.101.101): 56 data bytes
64 bytes from 10.11.101.101: icmp_seq=0 ttl=255 time=0.3 ms
64 bytes from 10.11.101.101: icmp_seq=1 ttl=255 time=0.2 ms
64 bytes from 10.11.101.101: icmp_seq=2 ttl=255 time=0.2 ms
64 bytes from 10.11.101.101: icmp_seq=3 ttl=255 time=0.2 ms
64 bytes from 10.11.101.101: icmp_seq=4 ttl=255 time=0.2 ms

--- 10.11.101.101 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.2/0.2/0.3 ms
```

To ping from a MicroSoft Windows PC

1. Open a command window.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate with four packets.

Other options include:

- `-t` to send packets until you press "Ctrl+C"
- `-a` to resolve addresses to domain names where possible
- `-n X` to send X ping packets and stop

Sample output:

```
C:\>ping 10.11.101.101

Pinging 10.11.101.101 with 32 bytes of data:
Reply from 10.11.101.101: bytes=32 time=10ms TTL=255
Reply from 10.11.101.101: bytes=32 time<1ms TTL=255
Reply from 10.11.101.101: bytes=32 time=1ms TTL=255
Reply from 10.11.101.101: bytes=32 time=1ms TTL=255

Ping statistics for 10.11.101.101:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 0ms, Maximum = 10ms, Average = 3ms
```

To ping from a Linux PC

1. Go to a shell prompt.
2. Enter `"ping 10.11.101.101"`.

Traceroute

Where ping will only tell you if it reached its destination and returned successfully, traceroute shows each step of the journey to its destination and how long each step takes. If ping finds an outage between two points, you can use traceroute to locate exactly where the problem is.

What is traceroute

Traceroute works by sending ICMP packets to test each hop along the route. It sends three packets, and then increases the time to live (TTL) setting by one each time. This effectively allows the packets to go one hop farther along the route. This is the reason why most traceroute commands display their maximum hop count before they start tracing the route, which is the maximum number of steps it takes before it declares the destination unreachable. Also, the TTL setting may result in steps along the route timing out due to slow responses. There are many possible reasons for this to occur.

By default, traceroute uses UDP datagrams with destination ports numbered from 33434 to 33534. The traceroute utility may also offer the option to select use of ICMP echo request (type 8) instead, which the Windows `tracert` utility uses. If you must, allow both protocols inbound through the FortiGate security policies (UDP with ports from 33434 to 33534 and ICMP type 8).

You can also use the packet count column of the **Policy & Objects > IPv4 Policy** (or, **Policy & Objects > IPv6 Policy**, if applicable) page to track traceroute packets. This allows you to verify the connection and confirm which security policy the traceroute packets are using.

What traceroute can tell you

Ping and traceroute have similar functions, which is to verify connectivity between two points. The big difference is that traceroute shows you each step of the way, where ping doesn't. Also, ping and traceroute use different protocols and ports, so one may succeed where the other fails.

You can verify your DNS connection using traceroute. If you enter an FQDN instead of an IP address for the traceroute, DNS tries to resolve that domain name. If the name isn't resolved, you have DNS issues.

How to use traceroute

The traceroute command varies slightly between operating systems. Note that in MicroSoft Windows, the command name is shortened to "tracert". Also, your output lists different domain names and IP addresses along your route.

To use traceroute on a MicroSoft Windows PC

1. Open a command window.
2. Enter "tracert fortinet.com" to trace the route from the PC to the Fortinet web site.

Sample output:

```
C:\>tracert fortinet.com

Tracing route to fortinet.com [208.70.202.225]
over a maximum of 30 hops:
 1 <1 ms <1 ms <1 ms 172.20.120.2
 2 66 ms 24 ms 31 ms 209-87-254-xxx.storm.ca [209.87.254.221]
 3 52 ms 22 ms 18 ms core-2-g0-0-1104.storm.ca [209.87.239.129]
 4 43 ms 36 ms 27 ms core-3-g0-0-1185.storm.ca [209.87.239.222]
 5 46 ms 21 ms 16 ms te3-x.1156.mpd01.cogentco.com [38.104.158.69]
 6 25 ms 45 ms 53 ms te8-7.mpd01.cogentco.com [154.54.27.249]
 7 89 ms 70 ms 36 ms te3-x.mpd01.cogentco.com [154.54.6.206]
 8 55 ms 77 ms 58 ms sl-st30-chi-.sprintlink.net [144.232.9.69]
 9 53 ms 58 ms 46 ms sl-0-3-3-x.sprintlink.net [144.232.19.181]
10 82 ms 90 ms 75 ms sl-x-12-0-1.sprintlink.net [144.232.20.61]
11 122 ms 123 ms 132 ms sl-0-x-0-3.sprintlink.net [144.232.18.150]
12 129 ms 119 ms 139 ms 144.232.20.7
13 172 ms 164 ms 243 ms sl-321313-0.sprintlink.net [144.223.243.58]
14 99 ms 94 ms 93 ms 203.78.181.18
15 108 ms 102 ms 89 ms 203.78.176.2
16 98 ms 95 ms 97 ms 208.70.202.225

Trace complete.
```

The first column on the left is the hop count, which can't exceed 30 hops. When that number is reached, the traceroute ends.

The second, third, and fourth columns display how much time each of the three packets takes to reach this stage of the route. These values are in milliseconds and normally vary quite a bit. Typically a value of <1ms indicates a local connection.

The fifth column (farthest to the right) shows the domain name of the device and its IP address, or possibly only the IP address.

To perform a traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter "traceroute fortinet.com".

The Linux traceroute output is very similar to the MicroSoft Windows tracert output.

To trace a route from a FortiGate to a destination IP address - CLI

```
# execute traceroute www.fortinet.com
traceroute to www.fortinet.com (66.171.121.34), 32 hops max, 84 byte packets
 1 172.20.120.2 0.637 ms 0.653 ms 0.279 ms
 2 209.87.254.221 <static-209-87-254-221.storm.ca> 2.448 ms 2.519 ms 2.458 ms
 3 209.87.239.129 <core-2-g0-2.storm.ca> 2.917 ms 2.828 ms 9.324 ms
 4 209.87.239.199 <core-3-bdi1739.storm.ca> 13.248 ms 12.401 ms 13.009 ms
 5 216.66.41.113 <v502.core1.tor1.he.net> 17.181 ms 12.422 ms 12.268 ms

14 66.171.121.34 <www.fortinet.com> 83.874 ms 84.084 ms 83.810 ms
```

How to check the logs

You might forget this step in troubleshooting, but it's an important one. Logging records the traffic that passes through the FortiGate to your network and what action the FortiGate takes when it scans the traffic. This information record is called a log message.

When you first configure FortiOS, log as much information as you can. If the logs that the FortiGate generates are too large, you can turn off or scale back the logging for features that you're not using.

As with most troubleshooting steps, before you can determine if the logs indicate a problem, you need to know what logs result from normal operation. Without a baseline it's difficult to troubleshoot.

When you troubleshoot with log files:

- Compare current logs to a recorded baseline of normal operation.
- If you need to, increase the level of logging (such as from Warning to Information) to obtain more information.

When increasing logging levels, ensure that you configure email alerts and select both disk usage and log quota. This ensures that you'll be notified if the increase in logging causes problems. Configure log settings by going to **Log & Report > Log Settings**.

Determine the activities that generate the most log entries:

- Check all logs to ensure important information isn't overlooked.
- Filter or order log entries based on different fields, such as level, service, or IP address, to look for patterns that may indicate a specific problem, such as frequent blocked connections on a specific port for all IP addresses.

Logs will help identify and locate any problems, but they will not solve the problems. The purpose of logs is to speed up your problem solving and save you time and effort.

For more information about logging and log reports, see the [Logging and Reporting handbook chapter](#).

How to verify the contents of the routing table (in NAT mode)

When a FortiGate has limited or no connectivity, a good place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves time and resources that you would spend performing a lookup. If a route is not used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures that the most recently used routes stay in the table. If your FortiGate is in transparent mode, you can't perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table, including local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the FortiGate GUI, use the Routing Monitor by going to **Monitor > Routing Monitor**.

In the CLI, use the command `get router info routing-table all`.

Sample output:

```
FGT# get router info routing-table all

Codes:
  K - kernel, C - connected, S - static, R - RIP, B - BGP
  O - OSPF, IA - OSPF inter area

C 172.20.120.0/24 is directly connected, wan1
```

How to verify the correct route is being used

If you have more than one default route and want to make sure that traffic is flowing as expected and through the right route, you can run a trace route from a machine in the local area network (LAN). This shows you the first hop that the traffic goes through.

Sample output:

```
C:\>tracert www.fortinet.com

Tracing route to www.fortinet.com [66.171.121.34]
over a maximum of 30 hops:

 1 <1 ms <1 ms <1 ms 10.10.1.99
 2 1 ms <1 ms <1 ms 172.20.120.2
 3 3 ms 3 ms 3 ms static-209-87-254-221.storm.ca [209.87.254.221]
 4 3 ms 3 ms 3 ms core-2-g0-2.storm.ca [209.87.239.129]
 5 13 ms 13 ms 13 ms core-3-bdi1739.storm.ca [209.87.239.199]
 6 12 ms 19 ms 11 ms v502.core1.tor1.he.net [216.66.41.113]
 7 22 ms 22 ms 21 ms 100ge1-2.core1.nyc4.he.net [184.105.80.9]
 8 84 ms 84 ms 84 ms ny-paix-gni.twgate.net [198.32.118.41]
 9 82 ms 84 ms 82 ms 217-228-160-203.TWGATE-IP.twgate.net [203.160.22
 8.217]
10 82 ms 81 ms 82 ms 229-228-160-203.TWGATE-IP.twgate.net [203.160.22
 8.229]
11 82 ms 82 ms 82 ms 203.78.181.2
12 84 ms 83 ms 83 ms 203.78.186.70
13 84 ms * 85 ms 66.171.127.177
14 84 ms 84 ms 84 ms fortinet.com [66.171.121.34]
15 84 ms 84 ms 83 ms fortinet.com [66.171.121.34]

Trace complete.
```

In this scenario, the first hop contains the IP address `10.10.1.99`, which is the internal interface of the FortiGate. The second hop contains the IP address `172.20.120.2`, to which the `wan1` interface of the FortiGate is connected, so we can conclude that the route through `wan1` interface is being used for this traffic.

You can also see the route taken for each session by debugging the packet flow in the CLI. For more information, see [How to debug the packet flow](#).

How to verify the correct firewall policy is being used

If you have more than one firewall policy, use the count column to check which policy is being used, the count must show traffic increasing. To do so, go to the **Policy & Objects > IPv4 Policy** or **Policy & Objects > IPv6 Policy** page.

Also, debugging the packet flow in the CLI shows the policy ID that's allowing the traffic. For more information about debugging the packet flow, see [How to debug the packet flow](#).

How to check the bridging information in transparent mode

When the FortiGate is set to transparent mode, it acts like a bridge and sends all incoming traffic out on the other interfaces. The bridge is between interfaces on the FortiGate.

Each bridge that's listed is a link between interfaces. Where traffic is flowing between interfaces, you can expect to find bridges listed. If you're having connectivity issues, and there are no bridges listed, that is a likely cause. Check for the MAC address of the interface or device in question.

How to check the bridging information

To list the existing bridge instances on the FortiGate, use the following command:

```
diagnose netlink brctl list
```

Sample output:

```
#diagnose netlink brctl list
list bridge information
1. root.b fdb: size=256 used=6 num=7 depth=2 simple=no
Total 1 bridges
```

How to display forwarding domain information

You can use forwarding domains, or collision domains, in routing to limit where packets are forwarded on the network. Layer 2 broadcasts are limited to the same group. By default, all interfaces are in group 0. For example, if the FortiGate has 12 interfaces, only two may be in the same forwarding domain, which limits packets that are broadcast to those two interfaces. This reduces traffic on the rest of the network.

Collision domains prevent the forwarding of ARP packets to all VLANs on an interface. Without collision domains, duplicate MAC addresses on VLANs may cause ARP packets to be duplicated. Duplicate ARP packets can cause some switches to reset. It's important to know what interfaces are part of which forwarding domains because this determines which interfaces can communicate with each other.

To manually configure forwarding domains in transparent mode, use the following CLI command:

```
config system interface
  edit <interface_name>
    set forward-domain <integer>
  end
```

To display the information for forward domains, use the following command:

```
diagnose netlink brctl domain <name> <id>
```

where <name> is the name of the forwarding domain to display and <id> is the domain ID.

Sample output

```
diagnose netlink brctl domain ione 101
show bridge root.b ione forward domain.
id=101 dev=trunk_1 6
```

To list the existing bridge MAC table, use the following command:

```
diagnose netlink brctl name host <name>
```

Sample output

```
show bridge control interface root.b host.
fdb: size=256, used=6, num=7, depth=2, simple=no
Bridge root.b host table
```

port no	device	devname	mac addr	ttl	attributes
2	7	wan2	02:09:0f:78:69:00	0	Local Static
5	6	vlan_1	02:09:0f:78:69:01	0	Local Static
3	8	dmz	02:09:0f:78:69:01	0	Local Static
4	9	internal	02:09:0f:78:69:02	0	Local Static
3	8	dmz	00:80:c8:39:87:5a	194	
4	9	internal	02:09:0f:78:67:68	8	
1	3	wan1	00:09:0f:78:69:fe	0	Local Static

To list the existing bridge port list, use the following command:

```
diagnose netlink brctl name port <name>
```

Sample output:

```
show bridge root.b data port.
trunk_1 peer_dev=0
internal peer_dev=0
dmz peer_dev=0
wan2 peer_dev=0
wan1 peer_dev=0
```

How to check the number of sessions that UTM proxy uses

Each FortiGate model has a limit for the maximum number of sessions that the UTM proxy supports. The UTM proxy handles all the traffic for the following protocols: HTTP, SMTP, POP3, IMAP, FTP, and NNTP. If the proxy

for a protocol fills up its session table, the FortiGate enters conserve mode, where it behaves differently, until entries and memory free up again.

Conserve or failopen mode

Once you reach the limit, depending on the conserve mode configuration on the FortiGate, no new sessions are created until old ones end. You can configure your the behavior FortiGate when memory is running low or the proxy connection limit has been reached. There are two related commands for this in the CLI:

```
config system global
  set av-failopen-session {enable | disable}
  set av-failopen { idledrop | off | one-shot | pass}
end
```

To set the behavior for these conditions, you must enable `av-failopen-session`. When it's enabled, and a proxy for a protocol runs out of room in its session table, that protocol goes into failopen mode and behaves as defined in the `av-failopen` command.

`av-failopen` determines the behavior of the proxy until entries are free in the session table again for that proxy.

- **idledrop** — This option removes idle sessions from the session table, starting with the clients that have the most sessions currently open. This method assumes that idle sessions aren't being used and it won't cause problems to close these sessions. This is usually true, but some applications may have problems opening a session. If this occurs, try another method to check if this is really the problem. This is a secure option as no unscanned traffic is allowed to pass.
- **off** — This option turns off accepting any new AV sessions, but continues to process any existing AV sessions that are currently active. All the protocols listed (HTTP, SMTP, POP3, IMAP, FTP, and NNTP) are scanned by FortiGate Antivirus. If AV scanning is enabled, `av-failopen off` is set, and the proxy session table fills up, which means that no new sessions of that type are accepted. For example, if the POP3 session table is full and email AV scanning is enabled, no additional POP3 connections are allowed until the session table gets some free space. This is a secure option because no unscanned traffic is allowed to pass.
- **one-shot** — When memory is low, bypass the antivirus system. The term `one-shot` comes from the fact that once you're in `one-shot av-failopen` mode, you must set `av-failopen` to either `pass` or `off` to restart AV scanning. This is a very unsecure option because it allows all traffic without AV scanning, and it never reverts to normal without manual assistance.
- **pass** — When memory is low, bypass the antivirus system. The difference between `pass` and `one-shot` options is that when memory is freed up, the system automatically starts AV scanning again. This is an unsecure option because it allows traffic to pass without AV scanning. However, it's better than `one-shot` because it automatically restarts AV scanning, when possible.

If the proxy session table is full for one or more protocols and your FortiGate enters into conserve or failopen mode, it appears as though the FortiGate has lost connection, network services are intermittent or don't exist, and yet other services work normally for a while until their sessions end and they join the queue of session-starved applications.

Checking sessions in use

To make troubleshooting this type of problem easier, sessions are broken down by which protocol they use. This provides you with statistics and errors specific to one of the protocols.

Due to the amount of output from this command, you should connect to the CLI with a terminal program, such as puTTY, that logs output. Otherwise, you may not be able to access all the output information from the command.

In the following output, only the HTTP entries are displayed. The other protocols have been removed in an attempt to shorten the output. There will be separate entries for each supported protocol (HTTP, SMTP, POP3, IMAP, FTP, and NNTP) in each section of the output.

To check sessions in use and related errors - CLI

```
FGT# # get test proxyworker 4

The output from this command falls into the following sections:

- **HTTP Common current connections** — This displays an entry for each protocol that displays the connections currently used, and the maximum connections allowed. This maximum is for the UTM proxy, which means all of the protocols connections combined can't be larger than this number. To support this, note that the maximum session count for each protocol is the same. You may also see a line titled `Max Concurrent Connections` for each protocol. This number is the maximum connections of this type that's allowed at one time. If VDOMs are enabled, this value is defined either on the global or per-VDOM level at **VDOM > Global Resources**.
- **Worker Stat** — This displays statistics about the UTM proxy including how long it has been running, and how many errors it has found.
- **HTTP Stat** — This section includes statistics about the HTTP protocol proxy. This is a very extensive list that includes errors, web responses, and any UTM positive matches. There are similar sections for each protocol, but the specific entries in each vary based on what UTM scanning is looking for in each — spam control for email, file transfer blocking for FTP, and so on.
- **Worker Accounting** — Lists accounting information about the UTM proxy such as polling statistics, how many sessions were scanned, and how many were just accepted. This information can show you if expected AV scanning is taking place or not. Under normal operation there shouldn't be errors or fails.
- **HTTP Accounting** — The accounting sections for each protocol provide information about successful session creation, failures, how many sessions are being scanned or filtered, and how many are client or server originated. If `setup_fail` is larger than zero, run the command again to see if it's increasing quickly. If it is, your FortiGate may be in conserve mode.

Related commands

To dump memory usage:

```
# get test proxyworker 1
```

To display statistics per VDOM:

```
# get test proxyworker 4444
```

To restart the proxy:

```
# get test proxyworker 99
```

How to examine the firewall session list

The firewall session list displays all sessions that the FortiGate has open. You can see if there are strange patterns, such as no sessions apart from the internal network, or all sessions are only to one IP address.

When you examine the firewall session list in the CLI, you can use filters to reduce the output. In the GUI, the filters are part of the interface.

To examine the firewall session list - GUI

Go to **FortiView > All Sessions**.

To examine the firewall session list - CLI

When you examine the firewall session list, there may be too many sessions to display. In this case, it's necessary to limit or filter the sessions displayed by source or destination address, or NAT'd address or port. If you want to filter by more than one of these, you need to enter a separate line for each value.

The following example shows filtering the session list based on a source address of 10.11.101.112:

```
FGT# diagnose system session filter src 10.11.101.112
FGT# diagnose system session list
```

The following example shows filtering the session list based on a destination address of 172.20.120.222.

```
FGT# diagnose system session filter dst 172.20.120.222
FGT# diagnose system session list
```

To clear all sessions corresponding to a filter - CLI

```
FGT# diagnose system session filter dst 172.20.120.222
FGT# diagnose system session clear
```

Check source NAT information

When you troubleshoot connections, remember NAT. NAT is especially important if you're troubleshooting from the remote end of the connection outside the firewall. On the **FortiView > All Sessions** list, pay attention to **NAT Source**, and **NAT Source Port**. These columns display the IP and port values after NAT has been applied.

Checking the NAT values can help you to ensure that they are the values you expect, and to ensure the remote end of the sessions can see the expected IP address and port number.

When you display the session list in the CLI, you can match the NAT'd source address (`nsrc`) and port (`nport`). This can be useful if multiple internal IP addresses are NAT'd to a common external-facing source IP address.

```
FGT# diagnose system session filter nsrc 172.20.120.122
FGT# diagnose system session filter nport 8888
FGT# diagnose system session list
```

How to check wireless information

Wireless connections, stations, and interfaces have different issues than other physical interfaces.

Troubleshooting station connection issue

To check whether a station entry is created on access control, use the following command:

```
FG600B3909600253 # diagnose wireless-controller wlaac -d sta
* vf=0 wtp=70 rId=2 wlan=open ip=0.0.0.0 mac=00:09:0f:db:c4:03 rssi=0 idle=148 bw=0 use=2
vf=0 wtp=70 rId=2 wlan=open ip=172.30.32.122 mac=00:25:9c:e0:47:88 rssi=-40 idle=0 bw=9
use=2
```

Enable diagnostics for a particular station

This example uses the station MAC address to find where it's failing:

```
FG600B3909600253 # diagnose wireless-controller wlaac sta_filter 00:25:9c:e0:47:88 1
Set filter sta 00:25:9c:e0:47:88 level 1
FG600B3909600253 # 71419.245 <ih> IEEE 802.11 mgmt::disassoc <== 00:25:9c:e0:47:88 vap
open rId 1 wId 0 00:09:0f:db:c4:03

71419.247 <cc> STA_CFG_RESP(34) 00:25:9c:e0:47:88 <== ws (0-192.168.35.1:5246) rc 0
(Success).
```

How to verify connectivity to FortiGuard

You can verify connectivity to FortiGuard in the **Licenses** widget on the FortiGate **Dashboard**. When your FortiGate is connected to FortiGuard, a green check mark appears for available FortiGuard services.

To verify connectivity from the CLI, use the `execute ping service.fortiguard.net` and `execute ping update.fortiguard.net` commands.

Sample output:

```
FG100D# execute ping service.fortiguard.net
PING guard.fortinet.net (208.91.112.196): 56 data bytes
64 bytes from 208.91.112.196: icmp_seq=0 ttl=51 time=61.0 ms
64 bytes from 208.91.112.196: icmp_seq=1 ttl=51 time=60.0 ms
64 bytes from 208.91.112.196: icmp_seq=2 ttl=51 time=59.6 ms
64 bytes from 208.91.112.196: icmp_seq=3 ttl=51 time=58.9 ms
64 bytes from 208.91.112.196: icmp_seq=4 ttl=51 time=59.2 ms

--- guard.fortinet.net ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 58.9/59.7/61.0 ms

FG100D# execute ping update.fortiguard.net
PING fds1.fortinet.com (208.91.112.68): 56 data bytes
64 bytes from 208.91.112.68: icmp_seq=0 ttl=53 time=62.0 ms
64 bytes from 208.91.112.68: icmp_seq=1 ttl=53 time=61.8 ms
64 bytes from 208.91.112.68: icmp_seq=2 ttl=53 time=61.3 ms
64 bytes from 208.91.112.68: icmp_seq=3 ttl=53 time=61.9 ms
64 bytes from 208.91.112.68: icmp_seq=4 ttl=53 time=61.8 ms
```

How to perform a sniffer trace (CLI and packet capture)

When you troubleshoot networks and routing in particular, it helps to look inside the headers of packets to determine if they're traveling along the route that you expect them to take. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your FortiGate has NP2, NP4, or NP6 interfaces that are offloading traffic, this will change the sniffer trace. Before you perform a trace on any NP2, NP4, or NP6 interfaces, you should disable offloading on those interfaces.

How do you sniff packets

Before you start sniffing packets on the CLI, you should prepare to capture the output to a file. A large amount of data may scroll by and you won't be able to see it without first saving it to a file. One method is to use a terminal program like `puTTY` to connect to the FortiGate CLI. Once the packet sniffing count is reached, you can end the session and analyze the output in the file.

The general form of the internal FortiOS packet sniffer command is:

```
diagnose sniffer packet <interface_name> <'filter'> <verbose> <count> <tsformat>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as “port1” or “internal”. This can also be “any” to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. “none” indicates no filtering, and all packets are displayed as the other arguments indicate. The filter must be inside single quotes (').
<verbose>	The level of verbosity as one of: 1 - print header of packets 2 - print header and data from IP of packets 3 - print header and data from Ethernet of packets 4 - print header of packets with interface name
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run until you stop it with <CTRL+C>.
<tsformat>	The format of timestamp. <ul style="list-style-type: none"> • a: absolute UTC time, yyyy-mm-dd hh:mm:ss.ms • l: absolute LOCAL time, yyyy-mm-dd hh:mm:ss.ms • otherwise: relative to the start of sniffing, ss.ms

For a simple sniffing example, enter the CLI command `diagnose sniffer packet port1 none 1 3`. This displays the next three packets on the port1 interface using no filtering, and verbose level 1. At this verbosity level, you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets and that 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diagnose sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]

0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

For a more advanced example of packet sniffing, the following commands will report packets on any interface that are traveling between a computer with the host name of “PC1” and a computer with the host name of “PC2”. With verbosity 4 and above, the sniffer trace displays the interface names where traffic enters or leaves the FortiGate unit. Remember to stop the sniffer, type CTRL+C.

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2>" 4

or

FGT# diagnose sniffer packet any "(host <PC1> or host <PC2>) and icmp" 4
```

The following CLI command for a sniffer includes the ARP protocol in the filter which may be useful to troubleshoot a failure in the ARP resolution (for example, PC2 may be down and not responding to the FortiGate ARP requests).

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2> or arp" 4
```

How do you use packet capture

To use packet capture, the FortiGate must have a disk. You can enable the `capture-packet` in the firewall policy, using the following CLI commands:

```
config firewall policy
  edit <id>
    set capture-packet enable
  end
```

To configure packet capture filters, go to **Network > Packet Capture**.

When you add a packet capture filter, enter the following information and select **OK**.

Interface	<p>Select the interface to sniff from the drop-down menu.</p> <p>You must select one interface. You can't change the interface without deleting the filter and creating a new one, unlike the other fields.</p>
Max Packets to Save	<p>Enter the number of packets to capture before the filter stops.</p> <p>This number can't be zero. You can halt the capturing before this number is reached.</p>
Enable Filters	Select this option to specify filter fields
Host(s)	<p>Enter the IP address of one or more hosts</p> <p>Separate multiple hosts with commas. To enter a range, use a dash without spaces, for example 172.16.1.5-172.16.1.15, or enter a subnet.</p>
Port(s)	<p>Enter one or more ports to capture on the selected interface.</p> <p>Separate multiple ports with commas. To enter a range, use a dash without spaces, for example 88-90</p>
VLAN(s)	<p>Enter one or more VLANs (if any).</p> <p>Separate multiple VLANs with commas.</p>
Protocol	Enter one or more protocols. Separate multiple protocols with commas. To enter a range, use a dash without spaces, for example 1-6, 17, 21-25.
Include IPv6 Packets	Select this option if you're troubleshooting IPv6 networking, or if your network uses IPv6. Otherwise, leave it disabled.

Include Non-IP Packets

The protocols in the list are all IP based except for ICMP (ping). To capture non-IP based packets, select this feature. Examples of non-IP packets include IPsec, IGMP, ARP, and ICMP.

If you select a filter, you have the option to start and stop packet capture in the edit window, or download the captured packets. You can also see the filter status and the number of packets captured.

You can select the filter and start capturing packets. When the filter is running, the number of captured packets increases until it reaches the **Max Packet Count** or you stop it. When the filter is running, you can't download the output file.

When the packet capture is complete, you can download the *.pcap file. You must use a third party application, such as Wireshark, to read *.pcap files. This tool provides you with extensive analytics and the full contents of the packets that were captured.

To start, stop, or resume packet capture, use the symbols on the screen. These symbols are the same as those used for audio or video playback. Hover over the symbol to reveal explanatory text. Similarly, to download the *.pcap file, use the download symbol on the screen.

For more information on troubleshooting with packet capture and packet sniffing, see ["Packet sniffing and packet capture" on page 2894](#).

How to debug the packet flow

Traffic should come in and leave the FortiGate. If you determine that network traffic isn't entering and leaving the FortiGate as expected, debug the packet flow.

You can only perform debugging using CLI commands. Debugging the packet flow requires that you enter a number of debug commands as each one configures part of the debug action, with the final command starting the debug.

If your FortiGate has FortiASIC NP4 or NP6 interface pairs that are offloading traffic, this changes the packet flow. Before you perform the debug on any NP4 or NP6 interfaces, you should disable offloading on those interfaces. Enter `diagnose npu <interface pair> fastpath disable`, where `interface pair` is `np4`, `np6`, `np4lite`, or `np6lite`.

The following configuration assumes that PC1 is connected to the internal interface of the FortiGate and has an IP address of 10.11.101.200. PC1 is the host name of the computer.

To debug the packet flow in the CLI, enter the following commands:

```
FGT# diagnose debug disable
FGT# diagnose debug flow filter add <PC1>
FGT# diagnose debug flow show console enable
FGT# diagnose debug flow show function-name enable
FGT# diagnose debug flow trace start 100
FGT# diagnose debug enable
```

The `start 100` argument in the above list of commands limits the output to 100 packets from the flow. This is useful to look at the flow without flooding your log or displaying too much information.

To stop all other debug activities, enter the command:

```
FGT# diagnose debug flow trace stop
```

The following is an example of debug flow output for traffic that has no matching security policy, and is in turn blocked by the FortiGate unit. The denied message indicates that the traffic was blocked.

```
id=20085 trace_id=319 func=resolve_ip_tuple_fast line=2825 msg="vd-root received a packet
(proto=6, 192.168.129.136:2854->192.168.96.153:1863) from port3."

```

Troubleshooting resources

Fortinet provides customers with resources of valuable information about FortiOS technical issues, including:

Technical documentation

Installation, Administration, and Quick Start Guides, as well as other technical documents, are available online at the [Fortinet Document Library](https://docs.fortinet.com): <https://docs.fortinet.com>

Fortinet video library

The [Fortinet Video Library](https://video.fortinet.com) hosts a collection of video which provide valuable information about Fortinet products.

<https://video.fortinet.com>

Release notes

Issues that arise after the technical documentation has been published will often be listed in the [Release Notes](#).

To find these, go to the [Fortinet Document Library](#).

<https://docs.fortinet.com/fortigate/release-information>

Knowledge base

The [Fortinet Knowledge Base](#) provides access to a variety of articles, white papers, and other documentation that provides technical insight into a range of Fortinet products. The Knowledge Base is available online at:

<http://kb.fortinet.com>

Fortinet technical discussion forums

An [online technical forum](#) allows administrators to contribute to discussions about issues that relate to their Fortinet products. Searching the forum can help an administrator identify if an issue has been experienced by another user. You can access the support forums at: <https://forum.fortinet.com/>

Fortinet training services online campus

The [Fortinet Training Services Online Campus](https://www.fortinet.com/training.html) hosts a collection of tutorials and training materials which you can use to increase your knowledge of Fortinet products. <https://www.fortinet.com/training.html>

Fortinet customer support

You defined your problem, researched a solution, put together a plan to find the solution, and executed that plan. At this point, if the problem hasn't been solved, it's time to contact [Fortinet Support](#) for assistance. Prepare yourself by reading [How to work with Fortinet Support](#) on Fortinet's Cookbook site.

<https://support.fortinet.com>

<http://cookbook.fortinet.com/how-to-work-with-fortinet-support/>

Chapter 28 - Virtual Domains

- [VDMs in NAT mode](#): detailed explanations and examples for configuring VDOM features for a FortiGate in NAT/route mode.
- [VDMs in transparent mode](#): detailed explanations and examples for configuring VDOM features for a FortiGate in transparent mode.
- [Inter-VDOM routing](#): concepts and scenarios for inter-VDOM routing.
- [Troubleshooting VDMs](#): diagnostic and troubleshooting information for some potential VDOM issues.

Before you begin using this guide, take a moment to note the following:

- By default, most FortiGate devices support 10 VDOMs. Many FortiGate models support purchasing a license key to increase the maximum number
 - This guide uses a FortiGate with interfaces named port1 through port4 for examples and procedures. The interface names on some models will vary. Where possible aliases for these ports are indicated to show their intended purpose and to help you determine which ports to use if your ports are labeled differently.
 - Administrators are assumed to be super_admin administrators unless otherwise specified. Some restrictions will apply to other administrators.
-

What's new in FortiOS 6.0

The following list contains new VDOM features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- ["Global security profiles" on page 2981](#)

Security profiles can still be created at the VDOM level, with that profile only available for that specific VDOM.

VDOMs overview

You can use virtual domains (VDOMs) to divide a FortiGate into two or more virtual devices that function independently. For each separate VDOM, you can create different configurations, including firewall policies, routing, VPNs, and security profiles.

Once you have created a VDOM, the steps you need to take to configure it are typically the same as if you were configuring a single FortiGate with VDOMs disabled. This chapter focuses on considerations that are unique to a network using VDOMs.

This section includes:

- [Benefits of virtual domains](#)
- [Enabling and accessing VDOMs](#)
- [Configuring additional VDOMs](#)

The Fortinet Security Fabric doesn't support FortiGate units with multiple VDOMs.

Benefits of virtual domains

VDOMs provide the following benefits:

- [Savings in physical space and power](#)
- [Using both NAT mode and transparent mode](#)
- [MSSP configuration](#)
- [Virtual clustering](#)

Savings in physical space and power

To increase the number of physical FortiGate devices, you require rack space, cables, and power. You also need to change your network configuration to accommodate the new devices. Finally, if you don't need as many devices in the future, you're left with expensive hardware that you aren't using.

Increasing the number of VDOMs requires no additional hardware and minimal changes to existing networking configurations. VDOMs save physical space and power. You're limited only by the size of your VDOM license and the physical resources of your FortiGate. By default, most FortiGate devices support a maximum of ten VDOMs, and many models allow you to buy a license to increase the maximum number of VDOMs.

Each physical FortiGate also requires a separate FortiGuard license to access security updates. VDOMs don't require you to buy separate licenses, as the same license is shared for all VDOMs located on the same FortiGate. When you update or upgrade the license, the changes are immediately available for all VDOMs.

Using both NAT mode and transparent mode

With multiple VDOMs, you can configure one VDOM configured in transparent mode and other VDOMs in NAT mode. In this configuration, you can use the transparent mode VDOM for troubleshooting your network and the NAT mode VDOMs for networking.

MSSP configuration

If you require a managed security service provider (MSSP) configuration, you can use VDOMs to provide a multi tenant solution, with each tenant's network connected to a unique VDOM that's configured to meet the network requirements. For each VDOM, you can either manage it globally using the management VDOM or allow tenants to manage their own VDOM.

Virtual clustering

Virtual clustering is an extension of FortiGate high availability for a cluster of two FortiGate units with multiple VDOMs. Virtual clustering provides failover protection for a multiple VDOM configuration and can load balance traffic between the VDOMs to improve overall network performance.

Virtual clustering load balancing efficiently load balances all traffic between VDOMs (including TCP and UDP traffic, UTM traffic and VoIP traffic) and can be adjusted in real time to actively optimize load sharing between the cluster units without affecting the smooth operation of the VDOMs in the cluster.

Enabling and accessing VDOMs

While a FortiGate VDOM is essentially the same as a physical FortiGate, there are some small differences. After you enable VDOMs on your FortiGate, you should take time to familiarize yourself with the changes.

This section includes:

- [The root VDOM](#)
- [Enabling virtual domains](#)
- [Global and per-VDOM settings](#)
- [Changes to the GUI and CLI](#)
- [Enabling and accessing VDOMs](#)
- [Resource settings](#)
- [Increasing the maximum number of VDOMs](#)

The root VDOM

On every FortiGate there is a root VDOM that you can't delete, whether or not VDOMs are enabled. When VDOMs are disabled, the root VDOM isn't visible because it doesn't need to be. When VDOMs are enabled, the root VDOM is visible. The root VDOM is the only VDOM available for configuration, until you

Typically, you use the root VDOM as the management VDOM. By connecting to the management VDOM, you can access the global settings for the FortiGate as well as the settings for each individual VDOM. You can set any VDOM to be the management VDOM.

Enabling virtual domains

VDOMs are disabled by default. To enable VDOMs, use the following instructions.

To enable VDOMs - GUI:

1. Go to **System > Settings**.
2. Under **Operations Settings**, enable **Virtual Domains**.

The FortiGate logs off all sessions. You can now log in again as admin.

To enable VDOMs - CLI:

```
config system global
    set vdom-admin enable
end
```

Global and per-VDOM settings

Settings that you configure outside a VDOM are called global settings. These settings affect the entire FortiGate and include areas such as interfaces, HA, maintenance, some antivirus, and some logging. In general, global settings are settings that should only be changed by your top level administrator.

Settings that you configure within a VDOM are called VDOM settings. These settings affect only a specific VDOM and include areas such as operating mode, routing, firewall, VPN, some antivirus, some logging settings, and reporting.

When virtual domains aren't enabled, the entire FortiGate is effectively a single VDOM, but per-VDOM limits apply. For some resource types, the global limit can't be reached with only one VDOM.

Changes to the GUI and CLI

When you enable VDOMs, the FortiGate GUI and the CLI change, allowing you to manage both global settings and per-VDOM settings. Only admin accounts using the super_admin profiles can access global options and settings for all VDOMs. Other administrator accounts can configure only the VDOM they're assigned to.

Other changes only affect either the GUI or the CLI.

GUI:

- When you access the management VDOM (this is the root VDOM by default), you can use the drop-down menu in the top left of the GUI to switch between global and per-VDOM settings. Some menu items only appear under **Global**, while others only appear as per-VDOM settings.
- A menu item is available at **Global > System > VDOM**. You use this to create, edit, and delete VDOMs.
- A menu item is available at **Global > System > Global Resources**. You use this to manage how system resources are shared between VDOMs.

CLI:

- To configure global settings, you must first enter the following CLI to select global options:

```
config global
```

- To configure per-VDOM settings, you must first enter the following CLI to select a VDOM:

```
config vdom
    edit <vdom_name>
```

Resource settings

Your FortiGate has a limited amount of hardware resources, such as memory, disk storage, and CPU operations. When you use VDOMs, you can control how resources are shared between each VDOM to optimize resource usage. This allows you to ensure the proper level of service is maintained on each VDOM.

For example, if one VDOM is connected to a web server and logging server, and a second VDOM is connected to an internal network of 20 users, these two VDOMs require different levels of resources. The first VDOM requires many sessions but no user accounts. The second VDOM is the opposite and requires user accounts and management resources, but fewer sessions.

Global resources

Global resources apply to the entire FortiGate. By default, the values are set to their maximum values. These values vary by FortiGate model because each model has different hardware capabilities. It can be useful to change the maximum values for some resources to ensure there is enough memory available for other resources that may be more important to your configuration.

To use the earlier example, if your FortiGate is protecting a number of web servers and other publicly accessible servers, you should maximize the available sessions and proxies and minimize other settings that are unused, such as user settings, VPNs, and dial-up tunnels.

To view the resource list, go to **Global > System > Global Resources**. You can also use the following CLI command:

```
config global
  config system resource-limits
  get
```

Note that some global resources are only visible if your FortiGate supports those resources. For example, the quota for logging to disk is only visible when your FortiGate has a hard disk.

For explicit proxies, when you configure limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources.

Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSAE, local database, etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.

For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

Per-VDOM resource settings

While global resources apply to resources shared by the entire FortiGate, per-VDOM resources are specific to only one VDOM. By default, all per-VDOM resource settings are set to allow the maximum.

Each VDOM has its own resource settings, including both maximum and minimum levels. The maximum level is the highest amount of that resource that the VDOM can use if it is available on the FortiGate. Minimum levels are guaranteed levels that are always available, no matter what resources the other VDOMs are using.

For example, one VDOM, called VDOM-1, has a maximum of 5000 sessions and a minimum of 1000 sessions. If the FortiGate has a global maximum of 20,000 sessions split among 10 VDOMs, it is possible that VDOM-1 won't be able to reach the 5000 session maximum. However, at all times VDOM-1 is guaranteed to have 1000 sessions available.

To view per-VDOM resource settings - GUI:

1. Select **Global > System > VDOM**.
2. Select the root VDOM, and select **Edit**.
3. Adjust the settings in the **Resource Usage** section of the page.
4. Select **OK**.

To view per-VDOM resource settings - CLI:

```
config global
  config system vdom-property
    edit root
    get
```

Increasing the maximum number of VDOMs

By default, most FortiGate models support configuring a maximum of 10 VDOMs. For certain models, you can purchase a license key to increase the maximum number of VDOMs.

To find out how many VDOMs your FortiGate can support, refer to the data sheet for your model. For more information, see the [Fortinet Data Sheets](#).

It is important to back up your configuration before upgrading the VDOM license on your FortiGate, especially if you're using HA mode.

To obtain a VDOM license key

1. Log in with a super_admin account.
2. Go to the **Dashboard**.
3. Record your FortiGate serial number as shown in **System Information** widget.
4. In the **License Information** widget, locate **Virtual Domain** and select **Purchase More**.

If you don't see the **Purchase More** option, your FortiGate model does not support more than 10 VDOMs.

5. You are taken to the [Fortinet Support website](#) where you can log in and purchase a license key.
6. After you receive your license key, go to the Dashboard and select **Upload License** under **License Information, Virtual Domains**.
7. In the **Input License Key** field, enter the 32-character license key you received from Fortinet Support.
8. Select **Apply**.

To verify the new VDOM license, in global configuration go to **System > Dashboard**. The **Licenses** widget shows the current number and total allowed number of VDOMs.

Configuring additional VDOMs

After enabling VDOMs, you can create additional VDOMs on your FortiGate and configure them for your network requirements.

This section includes:

- [Creating a VDOM](#)
- [Changing the management VDOM](#)
- [Adding interfaces to a VDOM](#)
- [Per-VDOM administrators](#)
- [Certificate management](#)
- [Disabling a VDOM](#)
- [Deleting a VDOM](#)

Creating a VDOM

You may experience reduced FortiGate performance if you create a large number of VDOMs.

To create new VDOMs, you must have a super_admin profile account. You must use the management VDOM (the root VDOM, by default) to create new VDOMs.

By default, new VDOMs are set to NAT/route operation mode. If you want a VDOM to be in transparent operation mode, you must manually change it using the CLI. For more information, see the [FortiOS CLI Reference](#).

To create a VDOM - GUI:

1. Connect to the management VDOM.
2. Go to **Global > System > VDOM** and select **Create New**.
3. Enter a unique **Name**. VDOM names have the following restrictions:
 - Only letters, numbers, “-”, and “_” are allowed
 - No more than 11 characters are allowed
 - No spaces are allowed
 - VDOMs can't have the same names as interfaces, zones, switch interfaces, or other VDOMs
4. Enter a short and descriptive comment to identify this VDOM.
5. Select **OK**.

To create a VDOM - CLI:

```
config system vdom
  edit <new_vdom_name>
end
```

If you want to edit an existing VDOM in the CLI and mistype the name, a new VDOM is created with this name.

The new VDOM can either be renamed or deleted. For more information, see [Deleting a VDOM](#).

Changing the management VDOM

You can't change the management VDOM if any administrators are using RADIUS authentication.

Once you have two or more VDOMs, you can change the management VDOM. The management VDOM must have Internet access.

You use the management VDOM to access global settings on the FortiGate, as well as for the following services:

- DNS lookups
- Logging to a FortiAnalyzer or syslog
- FortiGuard service
- Sending alert emails
- Network time protocol traffic (NTP)
- Sending SNMP traps
- Quarantining suspicious files and email

To change the management VDOM - GUI:

1. Select **Global > System > VDOM**.
2. Select the new management VDOM.
3. Select **Switch Management**.
4. Select **OK** to confirm the change.

To change the management VDOM - CLI:

```
config global
  config system global
    set management-vdom <vdom_name>
  end
end
```

Adding interfaces to a VDOM

Once you create a VDOM, you can add network interfaces to it. You can only assign an interface to a single VDOM. By default, all interfaces are assigned to the root VDOM.

If the existing configuration references an interface, you won't be able to change the VDOM assignment for that interface. Because some FortiGate models have a default configuration, you may need to delete existing policies and routes in order to add a particular interface to a new VDOM.

To add an interface to a VDOM - GUI:

1. Connect to the management VDOM.
2. Go to **Global > Network > Interfaces** and edit the interface.
3. Set **Virtual Domain** to the appropriate VDOM.
4. Select **OK**.

To add an interface to a VDOM - CLI:

```
config global
    config system interface
        edit <interface_name>
            set vdom <VDOM_name>
        next
    end
end
```

Per-VDOM administrators

After you enable VDOMs, you can create administrators with access to several VDOMs or limited to a single VDOM, called per-VDOM administrators.

Per-VDOM administrators must have either the `prof_admin` profile or a custom profile. Administrators who have the `super_admin` profile have access to all VDOMs on the FortiGate. For more information about administrator profiles, see the *System Administration handbook*.

Per-VDOM administrators must access the FortiGate through network interfaces that belong to those VDOMs, which must be configured to allow management access. The administrator can also connect using the console interface.

When per-VDOM administrators log into their virtual domain, they see a different dashboard than the global administrator sees. The VDOM dashboard displays information only relevant to that VDOM, while information about global settings or other VDOMs aren't shown.

Information	Per-VDOM	Global
System information	read-only	yes
License information	no	yes
CLI console	yes	yes
Unit operation	read-only	yes
Alert message console	no	yes
Top sessions	limited to VDOM sessions	yes
Traffic	limited to VDOM interfaces	yes
Statistics	yes	yes

You can create administrators globally or per-VDOM. In order to assign an administrator to multiple VDOMs, you must create the account at the global level. The steps for creating an administrator at the global level are shown below.

To create an administrator at the per-VDOM level, you use the same procedure used to create administrators on a FortiGate where VDOMs are disabled. However, the `super_admin` profile can't be used.

To create per-VDOM administrators - GUI:

1. Connect to the management VDOM.
2. Go to **Global > System > Administrators** and select **Create New**.
3. Set the **User Name** for the account.
4. Set and confirm the **Password**.
5. Set **Type** to **Local User**.
6. Remove the **root** VDOM from the **Virtual Domains** list, then add the appropriate VDOM.
7. Select **OK**.

To create per-VDOM administrators - CLI:

```
config global
  config system admin
    edit <name>
      set vdom <VDOM_name>
      set password <password>
      set accprofile <admin_profile>
      ...
    next
  end
end
```

Certificate management

Certificates can be uploaded to the FortiGate certificate store as either global or per-VDOM. Any certificates uploaded to the global certificate store will be available to all VDOMs on the FortiGate. A certificate uploaded to a VDOM-specific certificate store are only available for that VDOM.

The following factory default certificates are unique to each VDOM and are automatically generated when a new VDOM is added:

- Fortinet_CA_SSL
- Fortinet_SSL
- PositiveSSL_CA
- Fortinet_Wifi
- Fortinet_Factory

Disabling a VDOM

When you create a new VDOM, it's enabled by default. You can configure a VDOM only when it is enabled. You must enable the management VDOM.

Disabled VDOMs are considered offline. The configuration remains, but you can't use the VDOM and only the `super_admin` administrator can view it. You can assign interfaces to a disabled VDOM.

To disable a VDOM - GUI:

1. Go to **Global > System > VDOM**.
2. Open the VDOM for editing.
3. Ensure **Enable** is not selected.
4. Select **OK**.

To disable a VDOM - CLI:

```
config vdom
  edit <name>
    config system settings
      set status disable
    end
  end
```

Deleting a VDOM

You can only delete VDOMs that are enabled.

Deleting a VDOM removes it from the FortiGate configuration. You can't delete the root VDOM or the management VDOM.

You can only delete VDOMs that aren't referenced by the current configuration, including any per-VDOM objects. Before you delete a VDOM, check for, and remove the following objects that refer to that VDOM or its components:

- Routing - both static and dynamic routes
- Firewall addresses, policies, groups, or other settings
- Security profiles
- VPN configuration
- Users or user groups
- Logging
- DHCP servers
- Network interfaces, zones, and custom DNS servers
- VDOM administrators

Before you delete a VDOM, it's recommended that you re-assign interfaces assigned to that VDOM to the root VDOM.

To delete a VDOM - GUI:

1. Go to **Global > System > VDOM**.
2. Select the check box for the VDOM and then select the **Delete** icon.
3. Confirm the deletion.

To delete a VDOM - CLI:

```
config vdom
```

```
delete test-vdom
end
```

VDOMs in NAT mode

By default, VDOMs operate in NAT mode. In this mode, you install the VDOM as a gateway or router between two networks, typically a private network and the Internet. In this configuration, the VDOM uses network address translation (NAT) to hide the private IP addresses of network devices.

You can use VDOMs in NAT mode and transparent mode together on the same FortiGate. For more information about transparent mode, see ["VDOMs in transparent mode" on page 2964](#).

This chapter contains the following sections:

- [Using a VDOM in NAT/route mode](#)
- [Example configuration: VDOM in NAT/route mode](#)

Using a VDOM in NAT/route mode

This section contains information about how to configure a VDOM in NAT/route mode, including the following:

- [Configuring VDOM routing](#)
- [Configuring security policies](#)
- [Changing the inspection mode](#)
- [Using a VDOM in NAT/route mode](#)
- [Configuring VPNs for a VDOM](#)
- [Using a VDOM in NAT/route mode](#)

Configuring VDOM routing

Routing is VDOM-specific. Each VDOM should have a default static route configured as a minimum. Within a VDOM, routing is the same as routing on your FortiGate without VDOMs enabled.

When configuring dynamic routing on a VDOM, other VDOMs on the FortiGate can be neighbors. The following topics give a brief introduction to the routing protocols, and show specific examples of how to configure dynamic routing for VDOMs. Figures are included to show the FortiGate configuration after the successful completion of the routing example.

Default static route for a VDOM

The routing you define applies only to network traffic entering non-ssl interfaces belonging to this VDOM. Set the administrative distance high enough, typically 20, so that automatically configured routes will be preferred to the default.

In the following procedure, it is assumed that a VDOM called "Client2" exists. The procedure will create a default static route for this VDOM. The route has a destination IP of 0.0.0.0, on the port3 interface. It has a gateway of 10.10.10.1, and an administrative distance of 20.

The values used in this procedure are very standard, and this procedure should be part of configuring all VDOMs.

To add a default static route for a VDOM - GUI:

1. In **Virtual Domains**, select the client2 VDOM.
2. Go to **Network > Static Routes**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	10.10.10.1
Distance	20

To add a default static route for a VDOM - CLI:

```
config vdom
  edit client2
    config router static
      edit 4
        set device port2
        set dst 0.0.0.0 0.0.0.0
        set gateway 10.10.10.1
        set distance 20
      end
    end
  end
```

Dynamic routing in VDOMs

Dynamic routing is VDOM-specific, like all other routing. Dynamic routing configuration is the same with VDOMs as with your FortiGate without VDOMs enabled, once you're at the routing menu. If you have multiple VDOMs configured, the dynamic routing configuration between them can become quite complex.

VDOMs provide some interesting changes to dynamic routing. Each VDOM can be a neighbor to the other VDOMs. This is useful in simulating a dynamic routing area or AS or network using only your FortiGate.

You can separate different types of routing to different VDOMs if required. This allows for easier troubleshooting. This is very useful if your FortiGate is on the border of a number of different routing domains.

For more information on dynamic routing in FortiOS, see the *Networking Handbook*.

Inter-VDOM links must have IP addresses assigned to them if they are part of a dynamic routing configuration. Inter-VDOM links may or may not have IP addresses assigned to them. Without IP addresses, you need to be careful how you configure routing. While the default static route can be assigned an address of 0.0.0.0 and rely instead on the interface, dynamic routing almost always requires an IP address.

RIP

The RIP dynamic routing protocol uses hop count to determine the best route, with a hop count of 1 being directly attached to the interface and a hop count of 16 being unreachable. For example if two VDOMs on the same FortiGate are RIP neighbors, they have a hop count of 1.

OSPF

OSPF communicates the status of its network links to adjacent neighbor routers instead of the complete routing table. When compared to RIP, OSPF is more suitable for large networks, it is not limited by hop count, and is more complex to configure. For smaller OSPF configurations its easiest to just use the backbone area, instead of multiple areas.

BGP

BGP is an Internet gateway protocol (IGP) used to connect autonomous systems (ASes) and is used by Internet service providers (ISPs). BGP stores the full path, or path vector, to a destination and its attributes which aid in proper routing.

Configuring security policies

Security policies are VDOM-specific. This means that all firewall settings for a VDOM, such as firewall addresses and security policies, are configured within the VDOM.

In VDOMs, all firewall related objects are configured per-VDOM including addresses, service groups, security profiles, schedules, traffic shaping, and so on. If you want firewall addresses, you will have to create them on each VDOM separately. If you have many addresses, and VDOMs this can be tedious and time consuming. Consider using a FortiManager unit to manage your VDOM configuration — it can get firewall objects from a configured VDOM or FortiGate, and push those objects to many other VDOMs or FortiGate devices. See the [FortiManager Administration Guide](#).

You can customize the **Policy** display by including some or all columns, and customize the column order onscreen. Due to this feature, security policy screen shots may not appear the same as on your screen.

Configuring a security policy for a VDOM

Your security policies can involve only the interfaces, zones, and firewall addresses that are part of the current VDOM, and they are only visible when you're viewing the current VDOM. The security policies of this VDOM filter the network traffic on the interfaces and VLAN subinterfaces in this VDOM.

A firewall service group can be configured to group multiple services into one service group. When a descriptive name is used, service groups make it easier for an administrator to quickly determine what services are allowed by a security policy.

In the following procedure, it is assumed that a VDOM called `Client2` exists. The procedure will configure an outgoing security policy. The security policy will allow all HTTPS, SSH, and DNS traffic for the `SalesLocal` address group on `VLAN_200` going to all addresses on port3. This traffic will be scanned and logged.

To configure a security policy for a VDOM - GUI:

1. In **Virtual Domains**, select the `client2` VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Name	Client2-outgoing
Incoming Interface	VLAN_200
Outgoing Interface	port3
Source Address	SalesLocal
Destination Address	any
Schedule	always
Service	HTTPS, SSH, DNS
Action	ACCEPT
Log Allowed Traffic	enable

To configure a security policy for a VDOM - CLI:

```

config vdom
  edit Client2
    config firewall policy
      edit 12
        set srcintf VLAN_200
        set srcaddr SalesLocal
        set dstintf port3
        set dstaddr any
        set schedule always
        set service HTTPS SSH
        set action accept
        set status enable
        set logtraffic enable
      end
    end
  end

```

Changing the inspection mode

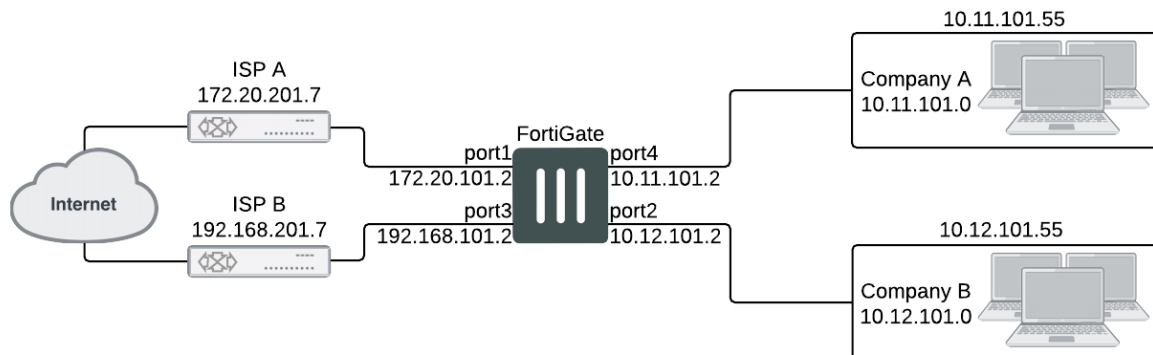

If you wish to change the inspection mode for a VDOM, go to **System > VDOM** and edit the VDOM you want to configure. Set **Inspection Mode** to either **Proxy** or **Flow-based**.

VDMs on the same FortiGate can use different inspection modes.

Configuring VPNs for a VDOM

Virtual Private Networking (VPN) settings are VDOM-specific, and must be configured within each VDOM. Configurations for IPsec Tunnel, IPsec Interface, PPTP and SSL are VDOM-specific.

Example configuration: VDOM in NAT/route mode

Company A and Company B each have their own internal networks and their own ISPs. They share a FortiGate that is configured with two separate VDOMs, with each VDOM running in NAT/route mode enabling separate configuration of network protection profiles. Each ISP is connected to a different interface on the FortiGate.

This network example was chosen to illustrate one of the most typical VDOM configurations.

This example has the following sections:

- [Network topology and assumptions](#)
- [General configuration steps](#)
- [Creating the VDOMs](#)
- [Configuring the FortiGate interfaces](#)
- [Configuring the vdomA VDOM](#)
- [Configuring the vdomB VDOM](#)
- [Testing the configuration](#)

Network topology and assumptions

Both companies have their own ISPs and their own internal interface, external interface, and VDOM on the FortiGate.

For easier configuration, the following IP addressing is used:

- all IP addresses on the FortiGate end in “.2” such as 10.11.101.2.
- all IP addresses for ISPs end in “.7”, such as 172.20.201.7.
- all internal networks are 10.*.* networks, and sample internal addresses end in “.55”.

The IP address matrix for this example is as follows.

Address	Company A	Company B
ISP	172.20.201.7	192.168.201.7
Internal network	10.11.101.0	10.012.101.0

Address	Company A	Company B
FortiGate / VDOM	172.20.201.2 (port1)	192.168.201.2 (port3)
	10.11.101.2 (port4)	10.012.101.2 (port2)

The Company A internal network is on the 10.11.101.0/255.255.255.0 subnet. The Company B internal network is on the 10.12.101.0/255.255.255.0 subnet.

There are no switches or routers required for this configuration.

There are no VLANs in this network topology.

The interfaces used in this example are port1 through port4. Different FortiGate models may have different interface labels. port1 and port3 are used as external interfaces. port2 and port4 are internal interfaces.

The administrator is a super_admin account. If you're using a non-super_admin account, refer to "Global and per-VDOM settings" to see which parts a non-super_admin account can also configure.

When configuring security policies in the CLI always choose a policy number that is higher than any existing policy numbers, select `services` before `profile-status`, and `profile-status` before `profile`. If these commands are not entered in that order, they may not be available to enter.

General configuration steps

For best results in this configuration, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. [Creating the VDOMs](#)
2. [Configuring the FortiGate interfaces](#)
3. [Configuring the vdomA VDOM](#), and [Configuring the vdomB VDOM](#)
4. [Testing the configuration](#)

Creating the VDOMs

In this example, two new VDOMs are created — vdomA for Company A and vdomB for Company B. These VDOMs will keep the traffic for these two companies separate while enabling each company to access its own ISP.

To create two VDOMs - GUI:

1. Log in with a super_admin account.
2. Go to **Global > System > VDOM**, and select **Create New**.
3. Enter `vdomA` and select **OK**.
4. Select **OK** again to return to the VDOM list.
5. Select **Create New**.
6. Enter `vdomB` and select **OK**.

To create two VDOMs - CLI:

```
config vdom
edit vdomA
next
```

```
edit vdomB
end
```

Configuring the FortiGate interfaces

This section configures the interfaces that connect to the companies' internal networks, and to the companies' ISPs.

All interfaces on the FortiGate will be configured with an IP address ending in ".2" such as 10.11.101.2. This will simplify network administration both for the companies, and for the FortiGate global administrator. Also the internal addresses for each company differ in the second octet of their IP address - Company A is 10.11.*, and Company B is 10.12.*.

This section includes the following topics:

- [Configuring the vdomA interfaces](#)
- [Configuring the vdomB interfaces](#)

If you can't change the VDOM of a network interface it is because something is referring to that interface that needs to be deleted. Once all the references are deleted the interface will be available to switch to a different VDOM. For example a common reference to the external interface is the default static route entry. See [Example configuration: VDOM in NAT/route mode](#).

Configuring the vdomA interfaces

The vdomA VDOM includes two FortiGate interfaces: port1 and external.

The port4 interface connects the Company A internal network to the FortiGate, and shares the internal network subnet of 10.11.101.0/255.255.255.0.

The external interface connects the FortiGate to ISP A and the Internet. It shares the ISP A subnet of 172.20.201.0/255.255.255.0.

To configure the vdomA interfaces - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select **Edit** on the port1 interface.
3. Enter the following information and select **OK**:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	172.20.201.2/255.255.255.0

4. Select **Edit** on the port4 interface.
5. Enter the following information and select **OK**:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	10.11.101.2/255.255.255.0

To configure the vdomA interfaces - CLI:

```

config global
config system interface
edit port1
set vdom vdomA
set mode static
set ip 172.20.201.2 255.255.255.0
next
edit port4
set vdom ABCDomain
set mode static
set ip 10.11.101.2 255.255.255.0
end

```

Configuring the vdomB interfaces

The vdomB VDOM uses two FortiGate interfaces: port2 and port3.

The port2 interface connects the Company B internal network to the FortiGate, and shares the internal network subnet of 10.12.101.0/255.255.255.0.

The port3 interface connects the FortiGate to ISP B and the Internet. It shares the ISP B subnet of 192.168.201.0/255.255.255.0.

To configure the vdomB interfaces - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select **Edit** on the port3 interface.
3. Enter the following information and select **OK**:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	192.168.201.2/255.255.255.0

4. Select **Edit** on the port2 interface.
5. Enter the following information and select **OK**:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	10.12.101.2/255.255.255.0

To configure the vdomB interfaces - CLI:

```

config global
config system interface
edit port3
set vdom vdomB
set mode static
set ip 192.168.201.2 255.255.255.0
next

```

```
edit port2
    set vdom vdomB
    set mode static
    set ip 10.12.101.2 255.255.255.0
end
```

Configuring the vdomA VDOM

With the VDOMs created and the ISPs connected, the next step is to configure the vdomA VDOM.

Configuring the vdomA includes the following:

- [Adding vdomA firewall addresses](#)
- [Adding the vdomA security policy](#)
- [Adding the vdomA default route](#)

Adding vdomA firewall addresses

You need to define the addresses used by Company A's internal network for use in security policies. This internal network is the 10.11.101.0/255.255.255.0 subnet.

The FortiGate provides one default address, "all", that you can use when a security policy applies to all addresses as the source or destination of a packet.

To add the vdomA firewall addresses - GUI:

1. In **Virtual Domains**, select **vdomA**.
2. Go to **Policy & Objects > Addresses**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Address Name	Ainternal
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0/255.255.255.0
Interface	port4

To add the ABCDomain VDOM firewall addresses - CLI:

```
config vdom
    edit vdomA
        config firewall address
            edit Ainternal
                set type ipmask
                set subnet 10.11.101.0 255.255.255.0
            end
        end
    end
```

Adding the vdomA security policy

You need to add the vdomA security policy to allow traffic from the internal network to reach the external network, and from the external network to internal as well. You need two policies for this domain.

To add the vdomA security policy - GUI:

1. In **Virtual Domains**, select **vdomA**.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Name	VDOMA-internal-to-external
Incoming Interface	port4
Outgoing Interface	port1
Source Address	Ainternal
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

5. Select **Create New**.
6. Enter the following information and select **OK**:

Name	VDOMA-external-to-internal
Incoming Interface	port1
Outgoing Interface	port4
Source Address	all
Destination Address	Ainternal
Schedule	Always
Service	ANY
Action	ACCEPT

To add the vdomA security policy - CLI:

```

config vdom
  edit vdomA
    config firewall policy
      edit 1
        set srcintf port4
        set srcaddr Ainternal
        set dstintf port1
        set dstaddr all
        set schedule always
        set service ANY
        set action accept

```

```

        set status enable
    next
    edit 2
        set srcintf port1
        set srcaddr all
        set dstintf port4
        set dstaddr Ainternal
        set schedule always
        set service ANY
        set action accept
        set status enable
    end

```

Adding the vdomA default route

You also need to define a default route to direct packets from the Company A internal network to ISP A. Every VDOM needs a default static route, as a minimum, to handle traffic addressed to external networks such as the Internet.

The administrative distance should be set slightly higher than other routes. Lower admin distances will get checked first, and this default route will only be used as a last resort.

To add a default route to the vdomA - GUI:

1. For **Virtual Domains**, select **vdomA**.
2. Go to **Network > Static Routes**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port1
Gateway	172.20.201.7
Distance	20

To add a default route to the vdomA - CLI:

```

config vdom
    edit vdomA
        config router static
            edit 1
                set device port1
                set gateway 172.20.201.7
            end
        end
    end

```

Configuring the vdomB VDOM

In this example, the vdomB VDOM is used for Company B. Firewall and routing settings are specific to a single VDOM.

vdomB includes the FortiGate port2 interface to connect to the Company B internal network, and the FortiGate port3 interface to connect to ISP B. Security policies are needed to allow traffic from port2 to external and from external to port2 interfaces.

This section includes the following topics:

- [Adding the vdomB firewall address](#)
- [Adding the vdomB security policy](#)
- [Adding a default route to the vdomB VDOM](#)

Adding the vdomB firewall address

You need to define addresses for use in security policies. In this example, the vdomB VDOM needs an address for the port2 interface and the “all” address.

To add the vdomB firewall address - GUI:

1. In **Virtual Domains**, select **vdomB**.
2. Go to **Policy & Objects > Addresses**.
3. Select **Create New**.
4. Enter the following information and select **OK**:

Address Name	Binternal
Type	Subnet / IP Range
Subnet / IP Range	10.12.101.0/255.255.255.0
Interface	port2

To add the vdomB firewall address - CLI:

```
config vdom
  edit vdomB
    config firewall address
      edit Binternal
        set type ipmask
        set subnet 10.12.101.0 255.255.255.0
      end
    end
  end
```

Adding the vdomB security policy

You also need a security policy for the Company B domain. In this example, the security policy allows all traffic.

To add the vdomB security policy - GUI:

1. Log in with a super_admin account.
2. In **Virtual Domains**, select vdomB.
3. Go to **Policy & Objects > IPv4 Policy**
4. Select **Create New**.
5. Enter the following information and select **OK**:

Name	VDOMB-internal-to-external
Incoming Interface	port2
Outgoing Interface	port3
Source Address	Binternal
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

6. Select **Create New**.
7. Enter the following information and select **OK**:

Name	VDOMB-external-to-internal
Incoming Interface	port3
Outgoing Interface	port2
Source Address	all
Destination Address	Binternal
Schedule	Always
Service	ANY
Action	ACCEPT

To add the vdomB security policy - CLI:

```

config vdom
  edit vdomB
    config firewall policy
      edit 1
        set srcintf port2
        set dstintf port3
        set srcaddr Binternal
        set dstaddr all
        set schedule always
        set service ANY
        set action accept
        set status enable
      edit 1
        set srcintf port3
        set dstintf port2
        set srcaddr all
        set dstaddr Binternal
        set schedule always
        set service ANY

```

```

        set action accept
        set status enable
    end
end

```

Adding a default route to the vdomB VDOM

You need to define a default route to direct packets to ISP B.

To add a default route to the vdomB VDOM - GUI:

1. Log in as the super_admin administrator.
2. In **Virtual Domains**, select vdomB.
3. Go to **Network > Static Routes**.
4. Select **Create New**.
5. Enter the following information and select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	192.168.201.7
Distance	20

To add a default route to the vdomB VDOM - CLI:

```

config vdom
  edit vdomB
    config router static
      edit 1
        set dst 0.0.0.0/0
        set device external
        set gateway 192.168.201.7
      end
    end
  end
end

```

Testing the configuration

Once you have completed configuration for both company VDOMs, you can use diagnostic commands, such as `tracert` in Windows, to test traffic routed through the FortiGate. Alternately, you can use the `traceroute` command on a Linux system with similar output.

Possible errors during the traceroute test are:

- “* * * Request timed out” - the trace was not able to make the next connection towards the destination fast enough
- “Destination host unreachable” - after a number of timed-out responses the trace will give up

Possible reasons for these errors are bad connections or configuration errors.

For additional troubleshooting, see [Troubleshooting VDOMs](#).

Testing traffic from the internal network to the ISP

In this example, a route is traced from the Company A internal network to ISP A. The test was run on a Windows PC with an IP address of 10.11.101.55.

The output here indicates three hops between the source and destination, the IP address of each hop, and that the trace was successful.

From the Company A internal network, access a command prompt and enter this command:

```
C:\>tracert 172.20.201.7
Tracing route to 172.20.201.7 over a maximum of 30 hops:
  1  <10 ms  <10 ms  <10 ms  10.11.101.2
  2  <10 ms  <10 ms  <10 ms  172.20.201.2
  3  <10 ms  <10 ms  <10 ms  172.20.201.7
Trace complete.
```

VDOMs in transparent mode

A VDOM in transparent mode is installed between the internal network and the router. In this mode, the VDOM does not make any changes to IP addresses and only applies security scanning to traffic. When a VDOM is added to a network in transparent mode, no network changes are required, except to provide the VDOM with a management IP address.

Each VDOM on a FortiGate can be configured for NAT/route mode or transparent mode, regardless of the operation mode of other VDOMs on the FortiGate. For more information about NAT/route mode, see ["VDOMs in NAT mode" on page 2949](#).

This chapter includes the following sections:

- [Transparent mode overview](#)
- [Using a VDOM in transparent mode](#)
- [VDOMs in transparent mode](#)

Transparent mode overview

In transparent mode, a VDOM becomes a layer-2 IP forwarding bridge. This means that Ethernet frames are forwarded based on destination MAC address, and no other routing is performed. All incoming traffic that is accepted by the firewall, is broadcast out on all interfaces.

In transparent mode the VDOM is a forwarding bridge, not a switch. A switch can develop a port table and associated MAC addresses, so that it can bridge two ports to deliver the traffic instead of broadcasting to all ports. In transparent mode, the VDOM does not follow this switch behavior, but instead is the forwarding bridge that broadcasts all packets out over all interfaces, subject to security policies.

Differences between NAT/route and transparent mode

The differences between NAT/route mode and transparent mode include:

Differences between NAT/route and transparent modes

Features	NAT/route mode	Transparent mode
Specific Management IP address required	No	Yes
Perform Network Address Translation (NAT)	Yes	Yes
Stateful packet inspection	Yes	Yes
Layer-2 forwarding	Yes	Yes
Layer-3 routing	Yes	No

Features	NAT/route mode	Transparent mode
Unicast Routing / Policy Based routing	Yes	No
DHCP server	Yes	No
IPsec VPN	Yes	Yes
PPTP/L2TP VPN	Yes	No
SSL VPN	Yes	No
Security features	Yes	Yes
VLAN support	Yes	Yes - limited to VLAN trunks.
Ping servers (dead gateway detection)	Yes	No

To provide administrative access to a FortiGate or VDOM in transparent mode, you must define a management IP address and a gateway. This step is not required in NAT/route mode where you can access the FortiGate through the assigned IP address of any interface where administrative access is permitted.

If you incorrectly set the transparent mode management IP address for your FortiGate, you will be unable to access your unit through the GUI. In this situation, you will need to connect to the FortiGate using the console cable and change the settings so you can access the unit. Alternately, if your unit has an LCD panel, you can change the operation mode and interface information through the LCD panel.

Operation mode differences in VDOMs

A VDOM, such as root, can have a maximum of 255 interfaces in Network Address Translation (NAT) mode or transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. To have more than a total of 255 interfaces configured, you need multiple VDOMs with multiple interfaces on each.

In transparent mode without VDOMs enabled, all interfaces on the FortiGate act as a bridge — all traffic coming in on one interface is sent back out on all the other interfaces. This effectively turns the FortiGate into a two interface unit no matter how many physical interfaces it has. When VDOMs are enabled, this allows you to determine how many interfaces to assign to a VDOM running in transparent mode. If there are reasons for assigning more than two interfaces based on your network topology, you're able to. However, the benefit of VDOMs in this case is that you have the functionality of transparent mode, but you can use interfaces for NAT/route traffic as well.

You can add more VDOMs to separate groups of VLAN subinterfaces. When using a FortiGate to serve multiple organizations, this configuration simplifies administration because you see only the security policies and settings for the VDOM you're configuring.

One essential application of VDOMs is to prevent problems caused when a FortiGate is connected to a layer-2 switch that has a global MAC table. FortiGate devices normally forward ARP requests to all interfaces, including VLAN subinterfaces. It is then possible for the switch to receive duplicate ARP packets on different VLANs. Some layer-2 switches reset when this happens. As ARP requests are only forwarded to interfaces in the same VDOM, you can solve this problem by creating a VDOM for each VLAN.

For more information about transparent mode, see the *Transparent Mode Handbook*.

Using a VDOM in transparent mode

The essential steps to configure a VDOM in transparent mode are:

- [Switching to transparent mode](#)
- [Adding VLAN subinterfaces](#)
- [Creating security policies](#)

You can also configure the security profiles that manage antivirus scanning, web filtering and spam filtering.

In transparent mode, you can access the GUI by connecting to an interface configured for administrative access and using HTTPS to access the management IP address. In the following examples, administrative access is enabled by default on the internal interface and the default management IP address is 10.11.0.1.

Switching to transparent mode

A VDOM is in NAT/route mode by default when it is created. You must switch it to transparent mode, and add a management IP address so you can access the VDOM from your management computer.

Before applying the change to transparent mode, ensure the VDOM has administrative access on the selected interface, and that the selected management IP address is reachable on your network.

Switching the VDOM to transparent mode can't be done through the GUI. It must be done through the CLI only.

To switch the VDOM to transparent mode - CLI:

```
config vdom
  edit <name>
    config system settings
      set opmode transparent
      set manageip 10.11.0.99 255.255.255.0
    end
  end
```

Adding VLAN subinterfaces

There are a few differences when adding VLANs in transparent mode compared to NAT/route mode.

In transparent mode, VLAN traffic is trunked across the VDOM. That means VLAN traffic can't be routed, changed, or inspected. For this reason when you assign a VLAN to a transparent mode VDOM, you will see the **Addressing Mode** section of the interface configuration disappear in from the GUI. It is because with no routing, inspection, or any activities able to be performed on VLAN traffic the VDOM simply re-broadcasts the VLAN traffic. This requires no addressing.

Also any routing related features such as dynamic routing or Virtual Router Redundancy Protocol (VRRP) are not available in transparent mode for any interfaces.

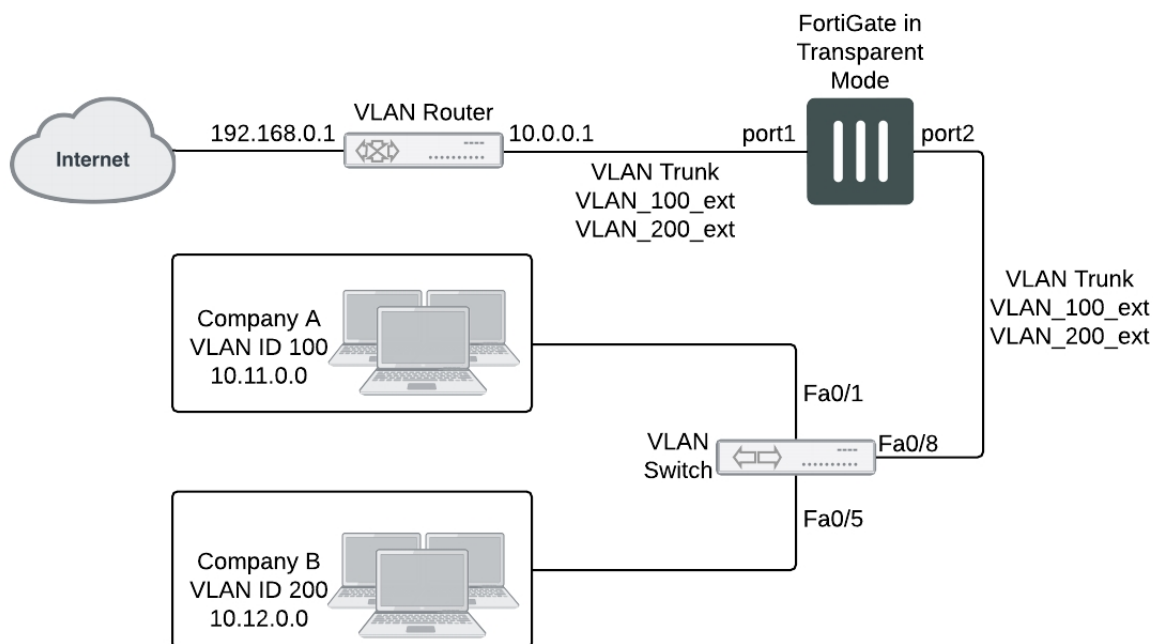

Creating security policies

Security policies permit communication between the FortiGate's network interfaces based on source and destination IP addresses. Typically you will also limit communication to desired times and services for additional security.

In transparent mode, the FortiGate performs antivirus and antispam scanning on each packet as it passes through the unit. You need security policies to permit packets to pass from the VLAN interface where they enter the unit to the VLAN interface where they exit the unit. If there are no security policies configured, no packets will be allowed to pass from one interface to another.

For more information, see the Firewall handbook.

Example configuration: VDOM in transparent mode

In this example, the FortiGate provides network protection to two organizations — Company A and Company B. Each company has different policies for incoming and outgoing traffic, requiring three different security policies and protection profiles.

VDOMs are not required for this configuration, but by using VDOMs the profiles and policies can be more easily managed on a per-VDOM basis either by one central administrator or separate administrators for each company. Also future expansion is simply a matter of adding additional VDOMs, whilst not disrupt the existing VDOMs.

For this example, firewalls are only included to deal with web traffic. This is to provide an example without making configuration unnecessarily complicated.

This example includes the following sections:

- [Network topology and assumptions](#)
- [General configuration steps](#)
- [Configuring common items](#)
- [Creating virtual domains](#)
- [Configuring the Company_A VDOM](#)
- [Configuring the Company_B VDOM](#)

- [Configuring the VLAN switch and router](#)
- [Testing the configuration](#)

Network topology and assumptions

Each organization's internal network consists of a different range of IP addresses:

- 10.11.0.0/255.255.0.0 for Company A.
- 10.12.0.0/255.255.0.0 for Company B.

For the procedures in this section, it is assumed that you have enabled VDOM configuration on your FortiGate. For more information, see [VDOMs overview](#).

The VDOM names are similar to the company names for easy recognition. The root VDOM can't be renamed and is not used in this example.

Interfaces used in this example are port1 and port2. Some FortiGate models may not have interfaces with these names. port1 is an external interface. port2 is an internal interface.

General configuration steps

The following steps summarize the configuration for this example. For best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. [Configuring common items](#)
2. [Creating virtual domains](#)
3. [Configuring the Company_A VDOM](#)
4. [Configuring the Company_B VDOM](#)
5. [Configuring the VLAN switch and router](#)
6. [Testing the configuration](#)

Configuring common items

Both VDOMs require you configure security profiles. These will be configured the same way, but need to be configured in both VDOMs.

The relaxed profile allows users to surf websites they are not allowed to visit during normal business hours. Also a quota is in place to restrict users to one hour of access to these websites to ensure employees don't take long and unproductive lunches.

To create a strict web filtering profile - GUI:

1. Go to the proper VDOM, and select **Security Profiles > Web Filter**.
2. Select **Create New**.
3. Enter `strict` for the **Name**.
4. Expand FortiGuard Web Filtering, and select block for all Categories except Business Oriented, and Other.
5. Block all Classifications except Cached Content, and Image Search.
6. Ensure **FortiGuard Quota** for all Categories and Classifications is Disabled.
7. Select **OK**.

To create a strict web filtering profile - CLI:

```

config vdom
  edit <vdom_name>
    config webfilter profile
      edit strict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
        set web-ftgd-err-log enable
      end
    end
  end
end

```

To create a relaxed web filtering profile - GUI:

1. Go to the proper VDOM, and select **Security Profiles > Web Filter**.
2. Select **Create New**.
3. Enter `relaxed` for the **Name**.
4. Expand FortiGuard Web Filtering, and select block for Potentially Security Violating Category, and Spam URL Classification.
5. Enable FortiGuard Quotas to allow 1 hour for all allowed Categories and Classifications.

Creating virtual domains

The FortiGate supports 10 virtual domains. Root is the default VDOM. It can't be deleted or renamed. The root VDOM is not used in this example. New VDOMs are created for Company A and Company B

To create the virtual domains - GUI:

1. With VDOMs enabled, select **Global > System > VDOM**.
2. Select **Create New**.
3. Enter `Company_A` for Name, and select **OK**.
4. Select **Create New**.
5. Enter `Company_B` for Name, and select **OK**.

To create the virtual domains - CLI:

```

config system vdom
  edit Company_A
  next
  edit Company_B
end

```

Configuring the Company_A VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company_A VDOM.

This section includes the following topics:

- [Adding VLAN subinterfaces](#)
- [Creating the Lunch schedule](#)
- [Configuring Company_A firewall addresses](#)
- [Creating Company_A security policies](#)

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the port2 interface and another one on the port1 interface, both with the same VLAN ID.

To add VLAN subinterfaces - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	VLAN_100_int
Interface	port2
VLAN ID	100
Virtual Domain	Company_A

4. Select **Create New**.
5. Enter the following information and select **OK**:

Name	VLAN_100_ext
Interface	port1
VLAN ID	100
Virtual Domain	Company_A

To add the VLAN subinterfaces - CLI:

```
config system interface
  edit VLAN_100_int
    set interface port2
    set vlanid 100
    set vdom Company_A
  next
  edit VLAN_100_ext
    set interface port1
    set vlanid 100
    set vdom Company_A
end
```

Creating the Lunch schedule

Both organizations have the same lunch schedule, but only Company A has relaxed its security policy to allow employees more freedom in accessing the Internet during lunch. Lunch schedule will be Monday to Friday from 11:45 AM to 2:00 PM (14:00).

To create a recurring schedule for lunchtime - GUI:

1. In Company_A VDOM, go to **Policy & Objects > Schedules**.
2. Select **Create New**.
3. Enter **Lunch** as the name for the schedule.
4. Select **Mon, Tues, Wed, Thu, and Fri**.
5. Set the **Start** time as **11:45** and set the **Stop** time as **14:00**.
6. Select **OK**.

To create a recurring schedule for lunchtime - CLI:

```
config vdom
  edit Company_A
    config firewall schedule recurring
      edit Lunch
        set day monday tuesday wednesday thursday friday
        set start 11:45
        set end 14:00
      end
    end
```

Configuring Company_A firewall addresses

For Company A, its networks are all on the 10.11.0.0 network, so restricting addresses to that domain provides added security.

To configure Company_A firewall addresses - GUI:

1. In the Company_A VDOM, go to **Policy & Objects > Addresses**.
2. Select **Create New**.
3. Enter **CompanyA** in the **Address Name** field.
4. Type **10.11.0.0/255.255.0.0** in the **Subnet / IP Range** field.
5. Select **OK**.

To configure vdomA firewall addresses - CLI:

```
config firewall address
  edit CompanyA
    set type ipmask
    set subnet 10.11.0.0 255.255.0.0
  end
```

Creating Company_A security policies

A security policy can include varying levels of security feature protection. This example only deals with web filtering. The following security policies use the custom security `strict` and `relaxed` profiles configured earlier.

For these security policies, we assume that all protocols will be on their standard ports, such as port 80 for HTTP traffic. If the ports are changed, such as using port 8080 for HTTP traffic, you will have to create custom services for protocols with non-standard ports, and assign them different names.

The firewalls configured in this section are:

- internal to external — always allow all, security features - web filtering: strict
- internal to external — Lunch allow all, security features - web filtering: relaxed

Security policies allow packets to travel between the internal VLAN_100 interface to the external interface subject to the restrictions of the protection profile. Entering the policies in this order means the last one configured is at the top of the policy list, and will be checked first. This is important because the policies are arranged so if one does not apply the next is checked until the end of the list.

To configure Company_A security policies - GUI:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	CompanyA-lunch
Incoming Interface	VLAN_100_int
Outgoing Interface	VLAN_100_ext
Source Address	CompanyA
Destination Address	all
Schedule	Lunch
Service	all
Action	ACCEPT
Security Features	enable
Web Filtering	relaxed

This policy provides relaxed protection during lunch hours — going from strict down to scan for protocol options and web filtering. AntiVirus and Email Filtering remain at strict for security — relaxing them would not provide employees additional access to the Internet and it would make the company vulnerable.

1. Select **Create New**.
2. Enter the following information and select **OK**:

Name	CompanyA-strict
Incoming Interface	VLAN_100_int
Outgoing Interface	VLAN_100_ext
Source Address	CompanyA
Destination Address	all
Schedule	always

Service	all
Action	ACCEPT
Security Features	enable
Web Filtering	strict

This policy enforces strict scanning at all times, while allowing all traffic. It ensures company policies are met for network security.

4. Verify that the policy list arranged **By Sequence** to make sure the CompanyA-lunch policy is located above the CompanyA-strict policy. If necessary, rearrange the policies so that the appropriate policy is applied to outgoing traffic.

To configure Company_A security policies - CLI:

```
config vdom
  edit Company_A
    config firewall policy
      edit 1
        set name "CompanyA-lunch"
        set srcintf VLAN_100_int
        set dstintf VLAN_100_ext
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule Lunch
        set webfiltering relaxed
      next
      edit 2
        set name "CompanyA-strict"
        set srcintf VLAN_100_int
        set dstintf VLAN_100_ext
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set webfiltering strict
      end
    end
  end
```

Configuring the Company_B VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company B VDOM.

This section includes the following topics:

- [Adding VLAN subinterfaces](#)
- [Creating Company_B service groups](#)
- [Configuring Company_B firewall addresses](#)
- [Configuring Company_B security policies](#)

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID.

To add VLAN subinterfaces - GUI:

1. Go to **Network > Interfaces**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	VLAN_200_int
Interface	port2
VLAN ID	200
Virtual Domain	Company_B

4. Select **Create New**.
5. Enter the following information and select **OK**:

Name	VLAN_200_ext
Interface	port1
VLAN ID	200
Virtual Domain	Company_B

To add the VLAN subinterfaces - CLI:

```
config system interface
  edit VLAN_200_int
    set interface internal
    set vlanid 200
    set vdom Company_B
  next
  edit VLAN_200_ext
    set interface external
    set vlanid 200
    set vdom Company_B
end
```

Creating Company_B service groups

Company_B does not want its employees to use any online chat software except NetMeeting, which the company uses for net conferencing. To simplify the creation of a security policy for this purpose, you create a service group that contains all of the services you want to restrict. A security policy can manage only one service or one group.

To create a chat service group - GUI:

1. Go to **Policy & Objects > Services** and select **Create New > Service Group**.
2. Enter `Chat` in the **Group Name** field.
3. For each of IRC, AOL, SIP-MSNmessenger and TALK, select the service in the **Available Services** list and select the right arrow to add it to the **Members** list.

If a particular service does not appear in the **Available Services** list, see the list in **Policy & Objects > Services**. Some services don't appear by default unless edited.

4. Select **OK**.

To create a games and chat service group - CLI:

```
config firewall service group
edit Chat
set member IRC SIP-MSNmessenger AOL TALK
end
```

Configuring Company_B firewall addresses

Company B's network is all in the 10.12.0.0 network. Security can be improved by only allowing traffic from IP addresses on that network.

To configure Company_B firewall address - GUI:

1. In the Company_B VDOM, go to **Policy & Objects > Addresses**.
2. Select **Create New**.
3. Enter `new` in the **Address Name** field.
4. Type `10.12.0.0/255.255.0.0` in the **Subnet / IP Range** field.
5. Select **OK**.

To configure Company_B firewall addresses - CLI:

```
config vdom
edit Company_B
config firewall address
edit all
set type ipmask
set subnet 10.12.0.0 255.255.0.0
end
```

Configuring Company_B security policies

Security policies allow packets to travel between the internal and external VLAN_200 interfaces subject to the restrictions of the protection profile.

To configure Company_B security policies - GUI:

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New**.
3. Enter the following information and select **OK**:

Name	CompanyB-deny-games-chat
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all
Destination Address	all
Schedule	BusinessDay
Service	games-chat
Action	DENY

This policy prevents the use of network games or chat programs (except NetMeeting) during business hours.

4. Enter the following information and select **OK**:

Name	CompanyB-lunch
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all
Destination Address	all
Schedule	Lunch
Service	HTTP, DNS
Action	ACCEPT
Security Features	enable
Web Filter	relaxed

This policy relaxes the web category filtering during lunch hour.

5. Select **Create New**.
6. Enter the following information and select **OK**:

Name	CompanyB-strict
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all

Destination Address	all
Schedule	BusinessDay
Service	HTTP, DNS
Action	ACCEPT
Security Profiles	enabled
Web Filter	strict

This policy provides rather strict web category filtering during business hours.

7. Select **Create New**.
8. Enter the following information and select **OK**:

Name	CompanyB-after-hours
Incoming Interface	VLAN_200_int
Outgoing Interface	VLAN_200_ext
Source Address	all
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT
Security Profiles	enabled
Web Filter	relaxed

Because it is last in the list, this policy applies to the times and services not covered in preceding policies. This means that outside of regular business hours, the Relaxed protection profile applies to email and web browsing, and online chat and games are permitted. Company B needs this policy because its employees sometimes work overtime. The other companies in this example maintain fixed hours and don't want any after-hours Internet access.

To configure Company_B security policies - CLI:

```
config firewall policy
  edit 1
    set name "CompanyB-deny-games-chat"
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set schedule BusinessDay
    set service Games
    set action deny
```

```
next
edit 2
    set name "CompanyB-lunch"
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule Lunch
    set service HTTP
    set profile_status enable
    set profile Relaxed
next
edit 3
    set name "CompanyB-strict"
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule BusinessDay
    set service HTTP
    set profile_status enable
    set profile BusinessOnly
next
edit 4
    set name "CompanyB-after-hours"
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set profile_status enable
    set profile Relaxed
end
```

Configuring the VLAN switch and router

The Cisco switch is the first VLAN device internal passes through, and the Cisco router is the last device before the Internet or ISP.

This section includes the following topics:

- [Configuring the Cisco switch](#)
- [Configuring the Cisco router](#)

Configuring the Cisco switch

On the Cisco Catalyst 2900 ethernet switch, you need to define the VLANs 100, 200 and 300 in the VLAN database, and then add configuration files to define the VLAN subinterfaces and the 802.1Q trunk interface.

Add this file to Cisco VLAN switch:

```
!
interface FastEthernet0/1
switchport access vlan 100
```

```

!
interface FastEthernet0/5
switchport access vlan 300
!
interface FastEthernet0/6
switchport trunk encapsulation dot1q
switchport mode trunk
!

```

Switch 1 has the following configuration:

Port 0/1	VLAN ID 100
Port 0/3	VLAN ID 200
Port 0/6	802.1Q trunk

Configuring the Cisco router

The configuration for the Cisco router in this example is the same as in the basic example, except we add VLAN_300. Each of the three companies has its own subnet assigned to it.

The IP addresses assigned to each VLAN on the router are the gateway addresses for the VLANs. For example, devices on VLAN_100 would have their gateway set to 10.11.0.1/255.255.0.0.

```

!
interface FastEthernet0/0
switchport trunk encapsulation dot1q
switchport mode trunk
!
interface FastEthernet0/0.1
encapsulation dot1Q 100
ip address 10.11.0.1 255.255.0.0
!
interface FastEthernet0/0.3
encapsulation dot1Q 200
ip address 10.12.0.1 255.255.0.0
!

```

The router has the following configuration:

Port 0/0.1	VLAN ID 100
Port 0/0.3	VLAN ID 200
Port 0/0	802.1Q trunk

Testing the configuration

Use diagnostic commands, such as `tracert`, to test traffic routed through the network.

You should test traffic between the internal VLANs as well as from the internal VLANs to the Internet to ensure connectivity.

For additional troubleshooting, see [Troubleshooting VDOMs](#).

This section includes the following topics:

- [Testing traffic from VLAN_100 to the Internet](#)
- [Testing traffic from VLAN_100 to VLAN_200](#)

Testing traffic from VLAN_100 to the Internet

In this example, a route is traced from VLANs to a host on the Internet. The route target is `www.example.com`.

From a host on VLAN_100, access a command prompt and enter this command:

```
C:\>tracert www.example.com
Tracing route to www.example.com [208.77.188.166]
over a maximum of 30 hops:
  1 <10 ms <10 ms <10 ms 10.100.0.1
  ...
 14 172 ms 141 ms 140 ms 208.77.188.166
Trace complete.
```

The number of steps between the first and the last hop, as well as their IP addresses, will vary depending on your location and ISP. However, all successful tracerts to `www.example.com` will start and end with these lines.

Repeat the tracert for VLAN_200.

The tracert for each VLAN will include the gateway for that VLAN as the first step. Otherwise, the tracert should be the same for each VLAN.

Testing traffic from VLAN_100 to VLAN_200

In this example, a route is traced between two internal networks. The route target is a host on VLAN_200. The Windows traceroute command `tracert` is used.

From VLAN_100, access a Windows command prompt and enter this command:

```
C:\>tracert 10.12.0.2
Tracing route to 10.12.0.2 over a maximum of 30 hops:
  1 <10 ms <10 ms <10 ms 10.100.0.1
  2 <10 ms <10 ms <10 ms 10.12.0.2
Trace complete.
```

You can repeat this for different routes in the topology. In each case the IP addresses will be the gateway for the starting VLAN, and the end point at the ending VLAN.

Security profiles and VDOMs

A single VDOM can use all the security features that are available to a FortiGate that does not use VDOMs. However, you can also create global security profiles which are available for use by multiple VDOMs. Both types of profiles can be used together in your configuration.

This chapter includes the following sections:

- [VDOM-level security profiles](#)
- [Global security profiles](#)
- [FortiGuard licensing](#)

VDOM-level security profiles

A single VDOM can use all the security features that are available to a FortiGate that does not use VDOMs.

For an administrator who can only access a single VDOM, security profiles are found in the same part of the GUI and the CLI as for a single FortiGate that does not use VDOMs.

For the global administrator, you must use the dropdown menu at the top of the GUI to access a specific VDOM. Once this is done, go to **Security Profiles** to configure VDOM-level profiles. In the CLI, these profiles can be configured under the command `config vdom`.

Global security profiles

Security profiles can be configured globally for use by multiple VDOMs, to avoid creating identical profiles for each VDOM individually. Global profiles are available for the following security features:

- Antivirus
- Application control
- Data leak prevention
- Intrusion protection
- Web filtering

Some security profile features, such as URL filters, are not available for use in a global profile.

The name for any global profile must start with "g-" for identification. Global profiles are available as read-only for VDOM-level administrators and can only be edited or deleted from within the global settings. Each security feature has at least one default global profile.

Global profiles are configured by going to **Global > Security Profiles** in the GUI or under the following `config global` commands in the CLI:

- `antivirus profile`
- `application list`
- `dlp sensor`
- `ips sensor`
- `webfilter profile`

Inter-VDOM routing

Inter-VDOM routing changes this allows VDOMs to communicate internally without using additional physical interfaces, using VDOM links. VDOM links are virtual interfaces that connect VDOMs. A VDOM link contains a pair of interfaces with each one connected to a VDOM, and forming either end of the inter-VDOM connection.

This chapter contains the following sections:

- [Benefits of inter-VDOM routing](#)
- [Configuring VDOM links](#)
- [Inter-VDOM configurations](#)
- [Dynamic routing over inter-VDOM links](#)
- [HA virtual clusters and VDOM links](#)
- [Example configuration: inter-VDOM routing](#)

Benefits of inter-VDOM routing

Inter-VDOM routing has a number of advantages over independent VDOM routing. These benefits include:

- [Freed-up physical interfaces](#)
- [More speed than physical interfaces](#)
- [Continued support for secure firewall policies](#)
- [Configuration flexibility](#)

Freed-up physical interfaces

Tying up physical interfaces on the FortiGate presents a problem. With a limited number of interfaces available, configuration options for the old style of communication between VDOMs are very limited. VLANs can be an answer to this, but they have some limitations.

For example, the FortiGate-800 has 8 physical ethernet ports. If they are assigned 2 per VDOM (one each for external and internal traffic) there can only be 4 VDOMs at most configured, not the 10 VDOMs the license will allow. Adding even one additional interface per VDOM to be used to communicate between VDOMs leaves only 2 VDOMs for that configuration, since it would required 9 interfaces for 3 VDOMs. Even using one physical interface for both external traffic and inter-VDOM communication would severely lower the available bandwidth for external traffic on that interface.

With the introduction of inter-VDOM routing, traffic can travel between VDOMs internally, freeing up physical interfaces for external traffic. Using the above example we can use the 4 VDOM configuration and all the interfaces will have their full bandwidth.

More speed than physical interfaces

Internal interfaces are faster than physical interfaces. Their speed depends on the FortiGate CPU and its load. That means that an inter-VDOM link interface will be faster than a outbound physical interface connected to another inbound physical interface.

However, while one virtual interface with normal traffic would be considerably faster than on a physical interface, the more traffic and more internal interfaces you configure, the slower they will become until they are slower than

the physical interfaces. CPU load can come from other sources such as AV or content scanning. This produces the same effect—internal interfaces such as inter-VDOM links will be slower.

Continued support for secure firewall policies

VDOMs help to separate traffic based on your needs. This is an important step in satisfying regulations that require proof of secure data handling. This is especially important to health, law, accounting, and other businesses that handle sensitive data every day.

By keeping things separate, traffic has to leave the FortiGate and re-enter to change VDOMs. This forces traffic to go through the firewall when leaving and enter through another firewall, keeping traffic secure.

With inter-VDOM routing, the need for the physical interfaces is greatly reduced. However, firewall policies still need to be in place for traffic to pass through any interface, physical or virtual, and thus provide the same level of security both internally and externally. Configuration of firewall policies is the same for inter-VDOM links as for any other interface, and your data will continue to have the high level of security.

Configuration flexibility

A typical VDOM uses at least two interfaces, typically physical interfaces, one for internal and one for external traffic. Depending on the configuration, more interfaces may be required. This means that the maximum number of VDOMs configurable on a FortiGate using physical interfaces is the number of interfaces available divided by two. VLANs can increase the number by providing multiple virtual interfaces over a single physical interface, but VLANs have some limitations. Using physical interfaces for inter-VDOM communication therefore limits the number of possible configurations on your FortiGate.

To overcome this limitation, inter-VDOM links can be created within the FortiGate. Using virtual interfaces, inter-VDOM links free up the physical interfaces for external traffic. Using VDOM links on a FortiGate with 8 physical interfaces, you can have 4 VDOMs communicating with each other (meshed configuration) and continue to have 2 physical interfaces each for internal and external connections. This configuration would have required 20 physical interfaces without inter-VDOM routing. With inter-VDOM routing it only requires 8 physical interfaces, with the other 12 interfaces being internal VDOM links.

Inter-VDOM routing allows you to make use of standalone VDOMs, Management VDOMs, and Meshed VDOMs without being limited by the number of physical interfaces on your FortiGate. For more information about these types of VDOMs, see ["Inter-VDOM configurations" on page 2983](#).

Inter-VDOM configurations

By using fewer physical interfaces to inter-connect VDOMs, inter-VDOM links provide you with more configuration options.

None of these configurations use VLANs to reduce the number of physical interfaces. It is generally assumed that an internal or client network will have its own internal interface and an external interface to connect to its ISP and the Internet.

These inter-VDOM configurations can use any FortiGate model with possible limitations based on the number of physical interfaces. VLANs can be used to work around these limitations.

There are four different types of inter-VDOM configurations:

- [Standalone VDOM](#)
- [Independent VDOMs](#)

- Management VDOM
- Meshed VDOM

Standalone VDOM

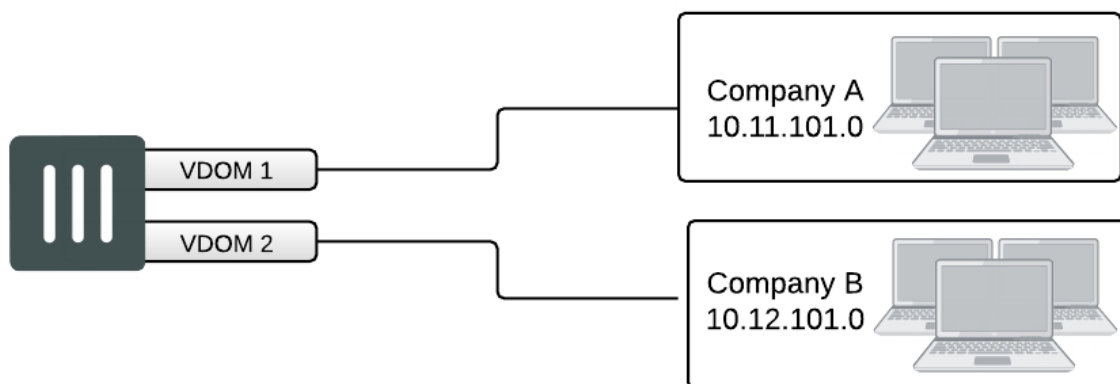

The standalone VDOM configuration uses a single VDOM on your FortiGate — the root VDOM that all FortiGate devices have by default. This is the VDOM configuration you're likely familiar with. It is the default configuration for FortiGate devices before you create additional VDOMs.

The configuration shown above has no VDOM inter-connections and requires no special configurations or settings.

The standalone VDOM configuration can be used for simple network configurations that only have one department or one company administering the connections, firewalls and other VDOM-dependent settings.

However, with this configuration, keeping client networks separate requires many interfaces, considerable firewall design and maintenance, and can quickly become time consuming and complex. Also, configuration errors for one client network can easily affect other client networks, causing unnecessary network downtime.

Independent VDOMs

The independent VDOMs configuration uses multiple VDOMs that are completely separate from each other. This is another common VDOM configuration.

This configuration has no communication between VDOMs and apart from initially setting up each VDOM, it requires no special configurations or settings. Any communication between VDOMs is treated as if communication is between separate physical devices.

The independent inter-VDOM configuration can be used where more than one department or one company is sharing the FortiGate. Each can administer the connections, firewalls and other VDOM-dependent settings for only its own VDOM. To each company or department, it appears as if it has its own FortiGate. This configuration reduces the amount of firewall configuration and maintenance required by dividing up the work.

However, this configuration lacks a management VDOM for VDOMs 1, 2, and 3. This management VDOM would enable an extra level of control for the FortiGate administrator, while still allowing each company or department to administer its own VDOM.

Management VDOM

In the management VDOM configuration, the root VDOM is the management VDOM. The other VDOMs are connected to the management VDOM with inter-VDOM links. There are no other inter-VDOM connections.

The inter-VDOM links connect the management VDOM to the other VDOMs. This does not require any physical interfaces, and the bandwidth of inter-VDOM links can be faster than physical interfaces, depending on the CPU workload.

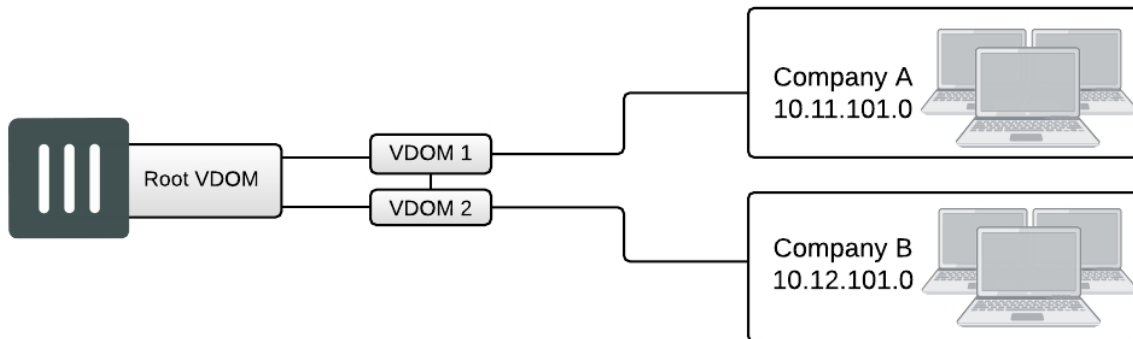

Only the management VDOM is connected to the Internet. The other VDOMs are connected to internal networks. All external traffic is routed through the management VDOM using inter-VDOM links and firewall policies between the management VDOM and each VDOM. This ensures the management VDOM has full control over access to the Internet, including what types of traffic are allowed in both directions. There is no communication directly between the non-root VDOMs. Security is greatly increased with only one point of entry and exit. Only the management VDOM needs to be fully managed to ensure network security in this case. Each client network can manage its own configuration without compromising security or bringing down another client network.

The management VDOM configuration is ideally suited for a service provider business. The service provider administers the management VDOM with the other VDOMs as customers. These customers don't require a dedicated IT person to manage their network. The service provider controls the traffic and can prevent the customers from using banned services and prevent Internet connections from initiating those same banned services. One example of a banned service might be Instant Messaging (IM) at a company concerned about intellectual property. Another example could be to limit bandwidth used by file-sharing applications without

banning that application completely. Firewall policies control the traffic between the customer VDOM and the management VDOM and can be customized for each customer.

The management VDOM configuration is limited in that the customer VDOMs have no inter-connections. In many situations this limitation is ideal because it maintains proper security. However, some configurations may require customers to communicate with each other, which would be easier if the customer VDOMs were inter-connected.

Meshed VDOM

The meshed VDOMs configuration, including partial and full mesh, has VDOMs inter-connected with other VDOMs. There is no special feature to accomplish this—they are just complex VDOM configurations.

Partial mesh means only some VDOMs are inter-connected. In a full mesh configuration, all VDOMs are inter-connected to all other VDOMs. This can be useful when you want to provide full access between VDOMs but handle traffic differently depending on which VDOM it originates from or is going to.

With full access between all VDOMs being possible, it is extra important to ensure proper security. You can achieve this level of security by establishing extensive firewall policies and ensuring secure account access for all administrators and users.

Meshed VDOM configurations can become complex very quickly, with full mesh VDOMs being the most complex. Ensure this is the proper solution for your situation before using this configuration. Generally, these configurations are seen as theoretical and are rarely deployed in the field.

Configuring VDOM links

Once VDOMs are configured on your FortiGate, configuring inter-VDOM routing and VDOM-links is very much like creating a VLAN interface. VDOM-links are managed through the GUI or CLI. In the GUI, VDOM link interfaces are managed in the network interface list.

This section includes the following topics:

- [Creating VDOM links](#)
- [IP addresses and inter-VDOM links](#)
- [Deleting VDOM links](#)
- [NAT to transparent VDOM links](#)

Creating VDOM links

VDOM links connect VDOMs together to allow traffic to pass between VDOMs as per firewall policies. Inter-VDOM links are virtual interfaces that are very similar to VPN tunnel interfaces except inter-VDOM links don't require IP addresses.

To create a VDOM link, you first create the point-to-point interface, and then bind the two interface objects associated with it to the virtual domains.

In creating the point-to-point interface, you also create two additional interface objects by default. They are called `vlink10` and `vlink11` - the interface name you chose with a 1 or a 0 to designate the two ends of the link.

Once the interface objects are bound, they are treated like normal FortiGate interfaces and need to be configured just like regular interfaces.

The assumptions for this example are as follows:

- Your FortiGate has VDOMs enabled and you have 2 VDOMs called `customer1` and `customer2` already configured. For more information on configuring VDOMs see [Configuring additional VDOMs](#).
- you're using a `super_admin` account.

To configure an inter-VDOM link - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select **Create New > VDOM link**, enter the following information, and select **OK**.

Name	vlink1
	(The name can be up to 11 characters long. Valid characters are letters, numbers, "-", and "_". No spaces are allowed.)
Interface #0	
Virtual Domain	customer1
IP/Netmask	10.11.12.13/255.255.255.0
Administrative Access	HTTPS, SSL
Interface #1	
Virtual Domain	customer2
IP/Netmask	172.120.100.13/255.255.255.0
Administrative Access	HTTPS, SSL

To configure an inter-VDOM link - CLI:

```
config global
  config system vdom-link
    edit vlink1
  end
  config system interface
    edit vlink10
      set vdom customer1
```

```
next
edit vlink11
    set vdom customer2
end
```

Once you have created and bound the interface ends to VDOMs, configure the appropriate firewall policies and other settings that you require. To confirm the inter-VDOM link was created, find the VDOM link pair and use the expand arrow to view the two VDOM link interfaces. You can select edit to change any information.

IP addresses and inter-VDOM links

Besides being virtual interfaces, here is one main difference between inter-VDOM links and regular interfaces—default inter-VDOM links don't require IP addresses. IP addresses are not required by default because an inter-VDOM link is an internal connection that can be referred to by the interface name in firewall policies, and other system references. This introduces three possible situations with inter-VDOM links that are:

- **unnumbered** - an inter-VDOM link with no IP addresses for either end of the tunnel
- **half numbered** - an inter-VDOM link with one IP address for one end and none for the other end
- **full numbered** - an inter-VDOM link with two IP addresses, one for each end.

Not using an IP address in the configuration can speed up and simplify configuration for you. Also you will not use up all the IP addresses in your subnets if you have many inter-VDOM links.

Half or full numbered interfaces are required if you're doing NAT, either SNAT or DNAT as you need an IP number on both ends to translate between.

You can use unnumbered interfaces in static routing, by naming the interface and using 0.0.0.0 for the gateway. Running traceroute will not show the interface in the list of hops. However you can see the interface when you're sniffing packets, which is useful for troubleshooting.

Deleting VDOM links

When you delete the VDOM link, the two link objects associated with it will also be deleted. You can't delete the objects by themselves. The example uses a VDOM routing connection called "vlink1". Removing vlink1 will also remove its two link objects vlink10 and vlink11.

Before deleting the VDOM link, ensure all policies, firewalls, and other configurations that include the VDOM link are deleted, removed, or changed to no longer include the VDOM link.

To remove a VDOM link - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select **Delete** for the VDOM link **vlink1**.

To remove a VDOM link - CLI:

```
config global
    config system vdom-link
        delete vlink1
    end
```

NAT to transparent VDOM links

Inter-VDOM links can be created between VDOMs in NAT mode and VDOMs in transparent mode, but it must be done through the CLI, as the VDOM link type must be changed from the default PPP to Ethernet for the two VDOMs to communicate. The below example assumes one vdom is in NAT mode and one is transparent mode.

An IP address must be assigned to the NAT VDOM interface, but no IP address should be assigned to the transparent VDOM interface.

To configure a NAT to transparent VDOM link - CLI:

```
config global
  config system vdom-link
    edit vlink1
      set type ethernet
    end
  config system interface
    edit vlink10
      set vdom (interface 1 name)
      set ip (interface 1 ip)
    next
    edit vlink11
      set vdom (interface 2 name)
    end
```

Ethernet-type is not recommended for standard NAT to NAT inter-VDOM links, as the default PPP-type link does not require the VDOM links to have addresses, while Ethernet-type does. VDOM link addresses are explained in [IP addresses and inter-VDOM links](#).

Dynamic routing over inter-VDOM links

BGP is supported over inter-VDOM links. Unless otherwise indicated, routing works as expected over inter-VDOM links.

If an inter-VDOM link has no assigned IP addresses to it, it may be difficult to use that interface in dynamic routing configurations. For example BGP requires an IP address to define any BGP router added to the network.

In OSPF, you can configure a router using a router ID and not its IP address. In fact, having no IP address avoids possible confusing between which value is the router ID and which is the IP address. However for that router to become adjacent with another OSPF router it will have to share the same subnet, which is technically impossible without an IP address. For this reason, while you can configure an OSPF router using an IP-less inter-VDOM link, it will likely be of limited value to you.

In RIP the metric used is hop count. If the inter-VDOM link can reach other nodes on the network, such as through a default route, then it may be possible to configure a RIP router on an inter-VDOM link. However, once again it may be of limited value due to limitations.

As stated earlier, BGP requires an IP address to define a router — an IP-less inter-VDOM link will not work with BGP.

In Multicast, you can configure an interface without using an IP address. However that interface will be unable to become an RP candidate. This limits the roles available to such an interface.

HA virtual clusters and VDOM links

FortiGate HA is implemented by configuring two or more FortiGate devices to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate, processing network traffic and providing normal security services such as firewall, VPN, IPS, virus scanning, web filtering, and spam filtering.

Virtual clustering extends HA features to provide failover protection and load balancing for a FortiGate operating with virtual domains. A virtual cluster consists of a cluster of two FortiGate devices operating with virtual domains. Traffic on different virtual domains can be load balanced between the cluster units.

With virtual clusters (vclusters) configured, inter-VDOM links must be entirely within one vcluster. You can't create links between vclusters, and you can't move a VDOM that is linked into another virtual cluster. If your FortiGate devices are operating in HA mode, with multiple vclusters when you create the vdom-link, the CLI command `config system vdom-link` includes an option to set which vcluster the link will be in.

What is virtual clustering?

Virtual clustering is an extension of the FGCP for FortiGate devices operating with multiple VDOMs enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Virtual clustering and failover protection

Virtual clustering operates on a cluster of two (and only two) FortiGate devices with VDOMs enabled. Each VDOM creates a cluster between instances of the VDOMs on the two FortiGate devices in the virtual cluster. All traffic to and from the VDOM stays within the VDOM and is processed by the VDOM. One cluster unit is the primary unit for each VDOM and one cluster unit is the subordinate unit for each VDOM. The primary unit processes all traffic for the VDOM. The subordinate unit does not process traffic for the VDOM. If a cluster unit fails, all traffic fails over to the cluster unit that is still operating.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You don't have to add a heartbeat interface for each VDOM.

Virtual clustering and HA override

For a virtual cluster configuration, override is enabled by default for both virtual clusters when you:

- Enable VDOM portioning from the GUI by moving virtual domains to virtual cluster 2
- Enter `set vcluster2 enable` from the CLI `config system ha` command to enable virtual cluster 2.

Usually you would enable virtual cluster 2 and expect one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. For this distribution to occur override must be enabled for both virtual clusters. Otherwise you will need to restart the cluster to force it to renegotiate.

Virtual clustering and load balancing or VDOM partitioning

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary unit receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

Note: If override is enabled the cluster may renegotiate too often. You can choose to disable override at any time. If you decide to disable override, for best results, you should disable it for both cluster units.

In a VDOM partitioning virtual clustering configuration, the HA mode is set to active-passive. Even though virtual clustering operates in active-passive mode you can configure a form of load balancing by using VDOM partitioning to distribute traffic between both cluster units. To configure VDOM partitioning you set one cluster unit as the primary unit for some virtual domains and you set the other cluster unit as the primary unit for other virtual domains. All traffic for a virtual domain is processed by the primary unit for that virtual domain. You can control the distribution of traffic between the cluster units by adjusting which cluster unit is the primary unit for each virtual domain.

For example, you could have 4 VDOMs, two of which have a high traffic volume and two of which have a low traffic volume. You can configure each cluster unit to be the primary unit for one of the high volume VDOMs and one of the low volume VDOMs. As a result each cluster unit will be processing traffic for a high volume VDOM and a low volume VDOM, resulting in an even distribution of traffic between the cluster units. You can adjust the distribution at any time. For example, if a low volume VDOM becomes a high volume VDOM you can move it from one cluster unit to another until the best balance is achieved. From the GUI you configure VDOM partitioning by setting the HA mode to active-passive and distributing virtual domains between Virtual Cluster 1 and Virtual Cluster 2. You can also configure different device priorities, port monitoring, and remote link failover, for Virtual Cluster 1 and Virtual Cluster 2.

From the CLI you configure VDOM partitioning by setting the HA mode to a-p. Then you configure device priority, port monitoring, and remote link failover and specify the VDOMs to include in virtual cluster 1. You do the same for virtual cluster 2 by entering the config secondary-vcluster command.

Failover protection does not change. If one cluster unit fails, all sessions are processed by the remaining cluster unit. No traffic interruption occurs for the virtual domains for which the still functioning cluster unit was the primary unit. Traffic may be interrupted temporarily for virtual domains for which the failed unit was the primary unit while processing fails over to the still functioning cluster unit. If the failed cluster unit restarts and rejoins the virtual cluster, VDOM partitioning load balancing is restored.

Example configuration: inter-VDOM routing

This example shows how to configure a FortiGate to use inter-VDOM routing.

This section contains the follow topics:

- [Network topology and assumptions](#)
- [Creating the VDOMs](#)
- [Configuring the physical interfaces](#)
- [Configuring the VDOM links](#)
- [Configuring the firewall and security profile settings](#)
- [Testing the configuration](#)

Network topology and assumptions

Two departments of a company, Accounting and Sales, are connected to one FortiGate 800 unit. To do its work, the Sales department receives a lot of email from advertising companies that would appear to be spam if the Accounting department received it. For this reason, each department has its own VDOM to keep firewall policies and other configurations separate. A management VDOM makes sense to ensure company policies are followed for traffic content.

The traffic between Accounting and Sales will be email and HTTPS only. It could use a VDOM link for a meshed configuration, but we will keep from getting too complex. With the configuration, inter-VDOM traffic will have a slightly longer path to follow than normal—from one department VDOM, through the management VDOM, and back to the other department VDOM. Since inter-VDOM links are faster than physical interfaces, this longer path should not be noticed.

Firewall policies will be in place. For added security, firewall policies will allow only valid office services such as email, web browsing, and FTP between either department and the Internet. Any additional services that are required can be added in the future.

The company uses a single ISP to connect to the Internet. The ISP uses DHCP to provide an IP address to the FortiGate. Both departments use the same ISP to reach the Internet.

Other assumptions for this example are as follows:

- Your FortiGate has interfaces labeled port1 through port4 and VDOMs are not enabled.
- you're using the super_admin account.
- You have the FortiClient application installed.
- you're familiar with configuring interfaces, firewalls, and other common features on your FortiGate.

General configuration steps

This example includes the following general steps. For best results, follow the steps in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. [Creating the VDOMs](#)
2. [Configuring the physical interfaces](#)
3. [Configuring the VDOM links](#)
4. [Configuring the firewall and security profile settings](#)
5. [Testing the configuration](#)

Creating the VDOMs

This procedure enables VDOMs and creates the Sales and Accounting VDOMs.

To create the VDOMs - GUI:

1. Log in as the super_admin administrator.
2. Go to the **Dashboard** and locate the **System Information** widget. Enable **Virtual Domain**.
3. Log in again.
4. Go to **Global > System > VDOM**.
5. Select **Create New**, enter `Accounting` for the VDOM Name, and select **OK**.
6. Select **Create New**, enter `Sales` for the VDOM Name, and select **OK**.

To create the VDOMs - CLI:

```

config system global
    set vdom enable
end
config system vdom
    edit Accounting
    next
    edit Sales
    next
end

```

Configuring the physical interfaces

Next, the physical interfaces must be configured. This example uses three interfaces on the FortiGate - port2 (internal), port3 (dmz), and port1 (external). Port2 and port3 interfaces each have a department's network connected. port1 is for all traffic to or from the Internet and will use DHCP to configure its IP address, which is common with many ISPs.

To configure the physical interfaces - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select **Edit** for the port2 interface, enter the following information, and select **OK**.

Alias	AccountingLocal
Virtual Domain	Accounting
Addressing mode	Manual
IP/Netmask	172.100.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the accounting department internal interface.

3. Select **Edit** for the port3 interface, enter the following information, and select **OK**.

Alias	SalesLocal
Virtual Domain	Sales
Addressing mode	Manual

IP/Netmask	192.168.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the sales department internal interface.

4. Select **Edit** for the port1 interface, enter the following information, and select **OK**.

Alias	ManagementExternal
Virtual Domain	root
Addressing Mode	DHCP
Distance	5
Retrieve default gateway from server	Enable
Override internal DNS	Enable
Administrative Access	HTTPS, SSH, SNMP
Description	This is the accounting department internal interface.

When the mode is set to DHCP or PPoE on an interface you can set the distance field. This is the administrative distance for any routes learned through the gateway for this interface. The gateway is added to the static route table with these values. A lower distance indicates a preferred route.

To configure the physical interfaces - CLI:

```
config global
config system interface
edit port2
set alias AccountingLocal
set vdom Accounting
set mode static
set ip 172.100.1.1 255.255.0.0
set allowaccess https ping ssh
set description "The accounting dept internal interface"
next
edit port3
set alias SalesLocal
set vdom Sales
set mode static
set ip 192.168.1.1 255.255.0.0
set allowaccess https ping ssh
set description "The sales dept. internal interface"
next
edit port1
set alias ManagementExternal
set vdom root
set mode DHCP
```

```

set distance 5
set gwdetect enable
set dns-server-override enable
set allowaccess https ssh snmp
set description "The system-wide management interface."
end

```

Configuring the VDOM links

To complete the connection between each VDOM and the management VDOM, you need to add the two VDOM links; one pair is the Accounting - management link and the other is for Sales - management link.

When configuring inter-VDOM links, you don't have to assign IP addresses to the links unless you're using advanced features such as dynamic routing that require them or want to add them for clarity. Not assigning IP addresses results in faster configuration, and more available IP addresses on your networks.

To configure the Accounting and management VDOM link - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select the expand arrow to select **Create New > VDOM link**.
3. Enter the following information, and select **OK**.

Name	AccountVlnk
Interface #0	
Virtual Domain	Accounting
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Accounting VDOM side of the link.
Interface #1	
Virtual Domain	root
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Management VDOM side of the link.

To configure the Accounting and management VDOM link - CLI:

```

config global
  config system vdom-link
    edit AccountVlnk
    next
  end
  config system interface
    edit AccountVlnk0
      set vdom Accounting

```

```

        set ip 0.0.0.0 0.0.0.0
        set allowaccess https ping ssh
        set description "Accounting side of the VDOM link"
    next
    edit AccountVlnk1
        set vdom root
        set ip 0.0.0.0 0.0.0.0
        set allowaccess https ping ssh
        set description "Management side of the VDOM link"
    end

```

To configure the Sales and management VDOM link - GUI:

1. Go to **Global > Network > Interfaces**.
2. Select the expand arrow and select **Create New > VDOM link**.
3. Enter the following information, and select **OK**.

Name	SalesVlnk
Interface #0	
Virtual Domain	Sales
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Sales VDOM side of the link.
Interface #1	
Virtual Domain	root
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Management VDOM side of the link.

To configure the Sales and management VDOM link - CLI:

```

config global
    config system vdom-link
        edit SalesVlnk
    end
config system interface
    edit SalesVlnk0
        set vdom Accounting
        set ip 0.0.0.0 0.0.0.0
        set allowaccess https ping ssh
        set description "Sales side of the VDOM link"
    next
    edit SalesVlnk1
        set vdom root

```

```
set ip 0.0.0.0 0.0.0.0
set allowaccess https ping ssh
set description "Management side of the VDOM link"
end
end
```

Configuring the firewall and security profile settings

With the VDOMs, physical interfaces, and VDOM links configured the firewall must now be configured to allow the proper traffic. Firewalls are configured per-VDOM, and firewall objects must be created for each VDOM separately.

For this example, the firewall group of services allowed between the internal networks and the Internet are the basic services for web browsing, file transfer, and email. These include: HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, and SMTP.

The only services allowed between Sales and Accounting are secure web browsing (HTTPS) and email (POP3 and SMTP).

The limited number of services ensures security between departments. The list of services can be expanded in the future if needed.

Security profile settings will block all non-essential business websites while logging all web traffic, scan and file filter all web and email protocols, and block game and peer-to-peer applications using application control.

For added security, FortiClient is required on internal computers with AntiVirus scanning configured. This is enforced by **Endpoint NAC** in firewall policies.

Using firewall addresses makes the firewall policies easier to read. Also if any changes need to be made in the future, you can simply update the addresses without changing the firewall policies. The addresses required are:

- AccountingLocal - all traffic from the internal accounting network
- AccountingVlnk - all traffic from the VDOM link between accounting and management VDOMs
- SalesLocal - all traffic from the internal sales network
- SalesVlnk - all traffic from the VDOM link between sales and management VDOM.

The Accounting VDOM requires AccountingLocal, AccountingVlnk, and SalesLocal. The Sales VDOM requires SalesLocal, SalesVlnk, and AccountingLocal.

This section includes the following topics:

- [Configuring firewall service groups](#)
- [Configuring security profile settings for the Accounting VDOM](#)
- [Configuring firewall settings for the Accounting VDOM](#)
- [Configuring security profile settings for the Sales VDOM](#)
- [Configuring firewall settings for the Sales VDOM](#)
- [Configuring firewall settings between the Accounting and Sales VDOMs](#)

Configuring firewall service groups

Service groups are an easy way to manage multiple services, especially if the same services are used on different networks.

The two service groups used here are intended for normal office traffic to the Internet, and for restricted traffic between departments. In both cases network traffic will be limited to the services listed to prevent any potential security risks or bandwidth-robbing applications.

These service groups can be changed as needed to either include additional valid services that are being used on the network, or to exclude services that are not required. Also, custom services can be created as needed for applications that are not listed.

To configure two firewall service groups - GUI:

1. Open the **Accounting** VDOM.
2. Go to **Policy & Objects > Services** and select **Create New > Service Group**.
3. Select **Create New**, enter the following information, and select **OK**.

Group Name	OfficeServices
Members	HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, PING, SMTP

4. Select **Create New**, enter the following information, and select **OK**.

Group Name	AccountingSalesServices
Members	HTTPS, POP3, PING, SMTP

To configure two firewall service groups - CLI:

```
config vdom
  edit Accounting
    config firewall service group
      edit OfficeServices
        set member HTTP HTTPS SSH FTP DNS NTP POP3 PING SMTP
      next
      edit AccountingSalesServices
        set member HTTPS POP3 PING SMTP
      end
    end
  end
```

Configuring security profile settings for the Accounting VDOM

Security profile settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that:

- the business environment is free from viruses
- employees don't access inappropriate websites
- employees don't use games or peer-to-peer applications at work

To configure web filtering for the Accounting VDOM - GUI:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > Web Filter**.
3. Select **Create New**.
4. Enter `webStrict` for the **Name**.

5. Select the arrow to expand the **FortiGuard Web Filtering** section.
6. Block all **Categories** except Business Oriented, Other, and Unrated.
7. Block all **Classifications** except Image Search.
8. Log all **Categories** and **Classifications**.
9. Select **OK**.

To configure AntiVirus for the Accounting VDOM - GUI:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > AntiVirus**.
3. Select **Create New**.
4. Enter `avStrict` for the **Name**.
5. Set **Detect Viruses** to **Block** and enable all **Inspected Protocols**.
6. Select **OK**.

To configure application control for the Accounting VDOM - GUI:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > Application Control**.
3. Select **Create New** (+ button at top right of page).
4. Enter `appStrict` for **Name** and select **OK**.
5. Select **Create New**.
6. In **Filters**, set **Category** to **game**.
7. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

8. Select **Create New**.
9. In **Filters**, set **Category** to **p2p**.
10. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

11. Select **Apply**.

To configure application control for the Accounting VDOM - CLI:

```
config vdom
  edit Accounting
    config application list
      edit appStrict
        config entries
          edit 1
            set category 2
          next
        
```

```

        edit 2
        set category 8
        end
    end
end

```

Configuring firewall settings for the Accounting VDOM

This configuration includes two firewall addresses and two firewall policies for the Accounting VDOM - one for the internal network, and one for the VDOM link with the management VDOM (root).

For added security, all traffic allowed will be scanned. Only valid office traffic will be allowed using the service group `OfficeServices`.

Note the spelling of `AccountVlnk` which is due to the eleven character limit on VDOM link names.

To configure firewall addresses - GUI:

1. Open the **Accounting** VDOM.
2. Select **Policy & Objects > Addresses**.
3. Select **Create New**, enter the following information, and select **OK**.

Address Name	AccountingLocal
Type	Subnet/ IP Range
Subnet / IP Range	172.100.0.0
Interface	port1

4. Select **Create New**, enter the following information, and select **OK**.

Address Name	AccountManagement
Type	Subnet/ IP Range
Subnet / IP Range	10.0.1.0
Interface	AccountVlnk

To configure firewall addresses - CLI:

```

config vdom
  edit Accounting
    config firewall address
      edit AccountingLocal
        set type iprange
        set subnet 172.100.0.0
        set associated-interface port1
      next
      edit AccountManagement
        set type iprange
        set subnet 10.0.1.0
        set associated-interface AccountVlnk
      end
    end
  end

```

end

To configure the firewall policies from AccountingLocal to the Internet - GUI:

1. Open the **Accounting** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**, enter the following information, and then select **OK**.

Name	Accounting-Local-to-Management
Incoming Interface	port2
Outgoing Interface	AccountVlnk
Source Address	AccountingLocal
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

4. Open the **root** VDOM.
5. Go to **Policy & Objects > IPv4 Policy**.
6. Select **Create New**, enter the following information, and then select **OK**.

Name	Accounting-VDOM-to-Internet
Incoming Interface	AccountVlnk
Outgoing Interface	ManagementExternal
Source Address	AccountManagement
Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT

Enable NAT	enable
Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

To configure the firewall policies from AccountingLocal to Internet - CLI:

```

config vdom
  edit Accounting
    config firewall policy
      edit 1
        set name "Accounting-Local-to-Management"
        set srcintf port2
        set dstintf AccountVlnk
        set srcaddr AccountingLocal
        set dstaddr AccountManagement
        set action accept
        set schedule always
        set service OfficeServices
        set nat enable
        set av-profile avStrict
        set webfilter-profile webStrict
        set application-list appStrict
      end
    end
  end
config vdom
  edit root
    config firewall policy
      edit 2
        set name "Accounting-VDOM-to-Internet"
        set srcintf AccountVlnk
        set dstintf port1
        set srcaddr AccountManagement
        set dstaddr all
        set action accept
        set schedule always
        set service OfficeServices
        set nat enable
        set av-profile scan
        set webfilter-profile scan
        set application-list AppControlList
      end
    end
  end

```

To configure the firewall policies from Internet to AccountingLocal - GUI:

1. Open the **root** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**, enter the following information, and select **OK**.

Name	Internet-access-to-Accounting-VDOM
Incoming Interface	port1
Outgoing Interface	AccountVlnk
Source Address	all
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

4. Open the **Accounting** VDOM.
5. Go to **Policy & Objects > IPv4 Policy**.
6. Select **Create New**, enter the following information, and select **OK**.

Name	Management-access-to-Accounting-local
Incoming Interface	AccountVlnk
Outgoing Interface	port2
Source Address	AccountManagement
Destination Address	AccountingLocal
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enabled
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict

To configure the firewall policies from Internet to AccountingLocal - CLI:

```
config vdom
  edit root
    config firewall policy
      edit 3
        set name "Internet-access-to-Accounting-VDOM"
        set srcintf port1
        set dstintf AccountVlnk
        set srcaddr all
        set dstaddr AccountManagement
        set action accept
        set schedule always
        set service OfficeServices
        set nat enable
        set av-profile avStrict
        set webfilter-profile webStrict
        set application-list appstrict
      end
    end
  config vdom
    edit Accounting
      config firewall policy
        edit 4
          set name "Management-access-to-Accounting-local"
          set srcintf AccountVlnk
          set dstintf port2
          set srcaddr AccountManagement
          set dstaddr AccountingLocal
          set action accept
          set schedule always
          set service OfficeServices
          set nat enable
          set av-profile avStrict
          set webfilter-profile webStrict
          set application-list appstrict
        end
      end
    end
  end
```

Configuring security profile settings for the Sales VDOM

Security profile settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that

- the business environment is free from viruses
- employees don't surf grossly inappropriate websites, and
- employees don't use games or peer-to-peer applications at work.

Note that Sales web traffic is different from Accounting, and web filtering is different to account for this.

To configure web filtering for the Sales VDOM - GUI:

1. Open the **Sales** VDOM.
2. Go to **Security Profiles > Web Filter**.
3. Select **Create New**.
4. Enter `webStrict` for the **Name**.

5. In **FortiGuard Categories**, select all of the categories except **Bandwidth Consuming**, **General Interest - Business** and **Unrated**.
6. In **Change Action for Selected Categories** select **Block**.
7. Select **Apply**.

To configure web filtering for the Sales VDOM - CLI:

```
config vdom
  edit Sales
    config webfilter profile
      edit webStrict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
        set web-ftgd-err-log enable
      end
    end
  end
```

To configure AntiVirus for the Sales VDOM - GUI:

1. Open the **Sales** VDOM.
2. Go to **Security Profiles > AntiVirus**.
3. Select **Create New**.
4. Enter `avStrict` for the **Name**.
5. Set **Detect Viruses** to **Block** and enable all **Inspected Protocols**.
6. Select **Apply**.

To configure AntiVirus for the Sales VDOM - CLI:

```
config vdom
  edit Sales
    config antivirus profile
      edit "avStrict"
        config http
          set options scan file-filter
        end
        config ftp
          set options scan file-filter
        end
        config imap
          set options scan file-filter
        end
        config pop3
          set options scan file-filter
        end
        config smtp
          set options scan file-filter
        end
        config nntp
          set options scan file-filter
        end
        config im
          set options scan file-filter
        end
      end
    end
  end
```

```

        end
        set filepattable 1
        set av-virus-log enable
        set av-block-log enable
    end
end

```

To configure application control for the Sales VDOM - GUI:

1. Open the **Accounting** VDOM.
2. Go to **Security Profiles > Application Control**.
3. Select **Create New** (+ button at top right of page).
4. Enter `appStrict` for **Name** and select **OK**.
5. Select **Create New**.
6. In **Filters**, set **Category** to **game**.
7. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

8. Select **Create New**.
9. In **Filters**, set **Category** to **p2p**.
10. In **Applications/Settings**, enter the following, and select **OK**.

Action	Block
Packet Logging	Enable

11. Select **Apply**.

To configure application control for the Sales VDOM - CLI:

```

config vdom
  edit Sales
    config application list
      edit "appStrict"
        config entries
          edit 1
            set category 2
          next
          edit 2
            set category 8
          end
        end
      end
    end
  end
end

```

Configuring firewall settings for the Sales VDOM

Like the Accounting firewall settings, this configuration includes two firewall addresses and two firewall policies for the sales VDOM: one for the internal network, and one for the VDOM link with the management VDOM.

When entering the CLI commands, the number of the firewall policies must be high enough to be a new policy. Depending on the number of firewall policies on your FortiGate, this may require starting at a higher number than the 6 required for the default configuration. This number is added automatically when you configure firewall policies using the web manager interface.

The FortiClient application must be used on Sales network computers to ensure additional protection for the sensitive information and for protection against spam.

To configure firewall addresses - GUI:

1. Open the **Sales** VDOM.
2. Go to **Policy & Objects > Addresses**.
3. Select **Create New**, enter the following information, and select **OK**.

Address Name	SalesLocal
Type	Subnet / IP Range
Subnet / IP Range	172.100.0.0
Interface	port3

4. Go to **Policy & Objects > Addresses**.
5. Select **Create New**, enter the following information, and select **OK**.

Address Name	SalesManagement
Type	Subnet / IP Range
Subnet / IP Range	10.0.1.0
Interface	SalesVlnk

To configure the firewall addresses - CLI:

```
config vdom
  edit Sales
    config firewall address
      edit SalesLocal
        set type iprange
        set subnet 172.100.0.0
        set associated-interface port2
      next
      edit SalesManagement
        set type iprange
        set subnet 10.0.1.0
        set associated-interface SalesVlnk
      end
    end
  end
```

To configure the firewall policies from SalesLocal to the Internet - GUI:

1. Open the **Sales** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.

3. Select **Create New**, enter the following information, and select **OK**.

Name	Sales-local-to-Management
Incoming Interface	port3
Outgoing Interface	SalesVlnk
Source Address	SalesLocal
Destination Address	SalesManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled

4. Open the **root** VDOM.
 5. Go to **Policy & Objects > IPv4 Policy**.
 6. Select **Create New**, enter the following information, and select **OK**.

Name	Sales-VDOM-to-Internet
Incoming Interface	SalesVlnk
Outgoing Interface	ManagementExternal
Source Address	SalesManagement
Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled

To configure the firewall policies from SalesLocal to the Internet - CLI:

```
config vdom
  edit root
    config firewall policy
      edit 6
        set name "Sales-local-to-Management"
        set srcintf port2
        set srcaddr SalesLocal
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service OfficeServices
        set action accept
```

```

        set logtraffic enable
    end
end
config vdom
    edit Sales
        config firewall policy
            edit 7
                set name "Sales-VDOM-to-Internet"
                set srcintf SalesVlnk
                set srcaddr SalesManagement
                set dstintf external
                set dstaddr all
                set schedule always
                set service OfficeServices
                set action accept
                set logtraffic enable
            end
        end
    end
end

```

To configure the firewall policies from the Internet to SalesLocal - GUI:

1. Open the **root** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**, enter the following information, and select **OK**.

Name	Internet-access-to-Sales-VDOM
Incoming Interface	ManagementExternal
Outgoing Interface	SalesVlnk
Source Address	all
Destination Address	SalesManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled

4. Open the **Sales** VDOM.
5. Go to **Policy & Objects > IPv4 Policy**.
6. Select **Create New**, enter the following information, and select **OK**.

Name	Management-access-to-Sales-local
Incoming Interface	SalesVlnk

Outgoing Interface	port2
Source Address	SalesManagement
Destination Address	SalesLocal
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled

To configure the firewall policies from the Internet to SalesLocal - CLI:

```

config vdom
  edit root
    config firewall policy
      edit 8
        set name "Internet-access-to-Sales-VDOM"
        set srcintf external
        set srcaddr all
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service OfficeServices
        set action accept
        set logtraffic enable
      end
    end
  config vdom
    edit Sales
      config firewall policy
        edit 9
          set name "Management-access-to-Sales-local"
          set srcintf SalesVlnk
          set srcaddr SalesManagement
          set dstintf port2
          set dstaddr SalesLocal
          set schedule always
          set service OfficeServices
          set action accept
          set logtraffic enable
        end
      end
    end
  end

```

Configuring firewall settings between the Accounting and Sales VDOMs

Firewall policies are required for any communication between each internal network and the Internet. Policies are also required for the two internal networks to communicate with each other through the management VDOM.

The more limited AccountingSalesServices group of services will be used between Sales and Accounting to ensure the traffic is necessary business traffic only. These policies will result in a partially meshed VDOM

configuration. The FortiClient application must be used to ensure additional protection for the sensitive accounting information.

Two firewall policies are required to allow traffic in both directions between Sales and Accounting.

To configure the firewall policy between Sales and Accounting on the management VDOM - GUI:

1. Open the **root** VDOM.
2. Go to **Policy & Objects > IPv4 Policy**.
3. Select **Create New**, enter the following information, and select **OK**.

Name	Sales-VDOM-to-Accounting-VDOM
Incoming Interface	SalesVlnk
Outgoing Interface	AccountVlnk
Source Address	SalesManagement
Destination Address	AccountingManagement
Schedule	always
Service	AccountingSalesServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled

4. Go to **Policy & Objects > IPv4 Policy**.
5. Select **Create New**, enter the following information, and select **OK**.

Name	Accounting-VDOM-to-Sales-VDOM
Incoming Interface	AccountVlnk
Outgoing Interface	SalesVlnk
Source Address	AccountingManagement
Destination Address	SalesManagement
Schedule	always
Service	AccountingSalesServices
Action	ACCEPT
Log Allowed Traffic	enabled

To configure the firewall policy between Sales and Accounting on the management VDOM - CLI:

```
config vdom
```

```
edit root
  config system firewall policy
    edit 9
      set name "Sales-VDOM-to-Accounting-VDOM"
      set srcintf SalesVlnk
      set srcaddr SalesManagement
      set dstintf AccountVlnk
      set dstaddr AccountManagement
      set schedule always
      set service AccountingSalesServices
      set action accept
      set logtraffic enable
    next
    edit 10
      set name "Accounting-VDOM-to-Sales-VDOM"
      set srcintf AccountVlnk
      set srcaddr AccountManagement
      set dstintf SalesVlnk
      set dstaddr SalesManagement
      set schedule always
      set service AccountingSalesServices
      set action accept
      set logtraffic enable
    end
  end
```

Testing the configuration

Once the inter-VDOM routing has been configured, tests must be conducted to confirm proper operation. If there are any problems, use the troubleshooting tips to resolve them.

This section includes the following topics:

- [Testing connectivity](#)
- [Troubleshooting Tips](#)

Testing connectivity

Testing connectivity ensures that physical networking connections as well as FortiGate interface configurations, including firewall policies, are properly configured.

The easiest way to test connectivity is to use the `ping` and `tracert` commands to confirm the connectivity of different routes on the network. Include testing:

- from AccountingLocal to Internet
- from Internet to AccountingLocal
- from SalesLocal to Internet
- from Internet to SalesLocal
- from AccountingLocal to SalesLocal.

When using the commands on a Windows computer, go to a command line prompt and enter either `ping <IP address>` or `tracert <IP address>`.

When using the commands on a FortiGate, go to the CLI and enter either `exec ping <IP address>` or `exec traceroute <IP address>`.

Troubleshooting Tips

When there are problems with connectivity, the following troubleshooting tips will help resolve the issues.

- If a multiple hop test, such as traceroute, is not successful then reduce it to a single hop to simplify the test. Test each link of the path to see which hop is down. If all hops are up, check the FortiGate policies to ensure they allow basic traffic to flow as expected.
- If ping does not work, confirm that the FortiGate interfaces have Ping enabled and also ensure Ping is enabled in the firewall policies. Otherwise the Ping traffic will be blocked.
- If one protocol does not work but others do work, check the FortiGate firewall policies for that one protocol to ensure it is allowed.
- If there are unexplained connectivity problems, check the local computer to ensure it does not have a software firewall running that may be blocking traffic. MS Windows computers have a firewall running by default that can cause problems.

For additional troubleshooting, see [Troubleshooting VDOMs](#).

Troubleshooting VDOMs

When you're configuring VDOMs you may run into some issues, with your VDOM configuration, your network configuration, or your device setup. This section addresses common problems and specific concerns that an administrator of a VDOM network may have.

This section includes:

- [VDOM admin having problems gaining access](#)
- [FortiGate running very slowly](#)
- [General VDOM tips and troubleshooting](#)

VDOM admin having problems gaining access

With VDOMs configured, administrators have an extra layer of permissions and may have problems accessing their information.

Confirm the admin's VDOM

Each administrator account, other than the super_admin account, is tied to one specific VDOM. That administrator is not able to access any other VDOM. It may be possible they are trying to access the wrong VDOM.

Confirm the VDOM interfaces

An administrator can only access their VDOM through interfaces that are assigned to that VDOM. If interfaces on that VDOM are disabled or unavailable there will be no method of accessing that VDOM by its local administrator. The super_admin will be required to either bring up the interfaces, fix the interfaces, or move another interface to that VDOM to restore access.

Confirm the VDOMs admin access

As with all FortiGate devices, administration access on the VDOM interfaces must be enabled for that VDOM administrators to gain access. For example, if SSH is not enabled, that is not available to administrators.

To enable admin access, the super_admin will go to the **Global > Network > Interfaces** page, and for the interface in question enable the admin access.

FortiGate running very slowly

You may experience a number of problems resulting from your FortiGate being overloaded. These problems may appear as:

- CPU and memory threshold limits exceeded on a continual basis
- Antivirus failopen happening on a regular basis
- dropped traffic or sessions due to lack of resources

These problems are caused by a lack of system resources. There are a number of possible reasons for this.

Too many VDOMs

If you have configured many VDOMs on your system, past the default ten VDOMs, this could easily be your problem.

Each VDOM you create on your FortiGate requires system resources to function - CPU cycles, memory, and disk space. When there are too many VDOMs configured there are not enough resources for operation. This may be a lack of memory in the session table, or no CPU cycles for processing incoming IPS traffic, or even a full disk drive.

Go to **Global > System > VDOM** and see the number of configured VDOMs on your system. If you're running 500 or more VDOMs, you must have a FortiGate 5000 chassis. Otherwise you need to reduce the number of VDOMs on your system to fix the problem. Even if you have the proper hardware, you may encounter noticeably slow throughput if you're using advanced features such as security profiles or deep content inspection with many configured VDOMs.

One or more VDOMs are consuming all the resources

If you have sufficient hardware to support the number of VDOMs you're running, check the global resources on your FortiGate. At a glance it will tell you if you're running out of a particular resource such as sessions, or users. If this is the case, you can then check your VDOMs to see if one particular VDOM is using more than its share of resources. If that is the case you can change the resource settings to allow that VDOM (or those VDOMs) fewer resources and in turn allow the other VDOMs access to those resources.

Too many security features in use

It is likely that reducing the security features in use regardless of number of VDOMs will greatly improve overall system performance and should be considered as an option.

Finally it is possible that your FortiGate configuration is incorrect in some other area, which is using up all your resources. For example, forgetting that you're running a network sniffer on an interface will create significant amounts of traffic that may prevent normal operation.

General VDOM tips and troubleshooting

Besides ping and traceroute, there are additional tools for troubleshooting your VDOM configurations. These include packet sniffing and debugging the packet flow.

Perform a sniffer trace

When troubleshooting networks, it helps to look inside the headers of packets to determine if they are traveling along the route you expect that they are. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your FortiGate has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, you should disable offloading on those interfaces.

What sniffing packets can tell you

If you're running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the FortiGate, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the FortiGate is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing, which prevents an IP packet from being forwarded if its Source IP does not either belong to a locally attached subnet (local interface), or be part of the routing between the FortiGate and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the FortiGate and cause many features to be turned off.

If you configure virtual IP addresses on your FortiGate, it will use those addresses in preference to the physical IP addresses. You will notice this when you're sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

When you're using VDOMs, you must be in a VDOM to access the `diag sniffer` command. At the global level, the command is not available. This is limit the packets only to the ones on your VDOM, and protects the privacy of other VDOM clients.

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as “port1” or “internal”. This can also be “any” to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. <code>none</code> indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (').
<verbose>	The level of verbosity as one of: 1 - print header of packets 2 - print header and data from IP of packets 3 - print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run forever until you stop it with <CTRL C>.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955 ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757 ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614 ack 3314279933
```

For a more advanced example of packet sniffing, the following commands will report packets on any interface traveling between a computer with the host name of PC1 and the computer with the host name of PC2. With verbosity 4 and above, the sniffer trace will display the interface names where traffic enters or leaves the FortiGate. Remember to stop the sniffer, type CTRL+C. Note that PC1 and PC2 may be VDOMs.

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2>" 4
```

or

```
FGT# diagnose sniffer packet any "(host <PC1> or host <PC2>) and icmp" 4
```

The following sniffer CLI command includes the ARP protocol in the filter which may be useful to troubleshoot a failure in the ARP resolution (for instance PC2 may be down and not responding to the FortiGate ARP requests).

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2> or arp" 4
```

Debugging the packet flow

Traffic should come in and leave the VDOM. If you have determined that network traffic is not entering and leaving the VDOM as expected, debug the packet flow.

Debugging can only be performed using CLI commands. Debugging the packet flow requires a number of debug commands to be entered as each one configures part of the debug action, with the final command starting the debug.

If your FortiGate has NP interfaces that are offloading traffic, this will change the packet flow. Before performing the debug on any NP interfaces, you should disable offloading on those interfaces.

The following configuration assumes that PC1 is connected to the internal interface of the FortiGate and has an IP address of 10.11.101.200. PC1 is the host name of the computer.

To debug the packet flow in the CLI, enter the following commands:

```
FGT# diag debug enable
FGT# diag debug flow filter add <PC1>
FGT# diag debug flow show console enable
FGT# diag debug flow trace start 100
FGT# diag debug enable
```

The `start 100` argument in the above list of commands will limit the output to 100 packets from the flow. This is useful for looking at the flow without flooding your log or your display with too much information.

To stop all other debug activities, enter the command:

```
FGT# diag debug flow trace stop
```

The following is an example of debug flow output for traffic that has no matching Firewall Policy, and is in turn blocked by the FortiGate. The denied message indicates the traffic was blocked. Note that even with VDOMs not enabled, vd-root is still shown.

```
id=20085 trace_id=319 func=resolve_ip_tuple_fast line=2825 msg="vd-root received a
packet(proto=6, 192.168.129.136:2854->192.168.96.153:1863) from port3."

id=20085 trace_id=319 func=resolve_ip_tuple line=2924 msg="allocate a new session-
013004ac"

id=20085 trace_id=319 func=vf_ip4_route_input line=1597 msg="find a route: gw-
192.168.150.129 via port1"

id=20085 trace_id=319 func=fw_forward_handler line=248 msg=" Denied by forward policy
check"
```

Virtual FortiOS (Private Cloud Administration Guide)

This document describes how to deploy a FortiGate virtual appliance in several virtualization server environments. This includes how to configure the virtual hardware settings of the virtual appliance.

This document assumes:

- you have already successfully installed the virtualization server on the physical machine,
- you have installed appropriate VM management software on either the physical server or a computer to be used for VM management.

This document does not cover configuration and operation of the virtual appliance after it has been successfully installed and started. For these issues, see the FortiGate Handbook.

This document includes the following sections:

- [Virtual FortiOS overview](#)
- [Deployment example – VMware](#)
- [Deployment example – MS Hyper-V](#)
- [Deployment example – KVM](#)
- [Deployment example – Open Xen](#)
- [Deployment example – Citrix XenServer](#)

What's new in virtual FortiOS 6.0.1

The following list contains new firewall features added in FortiOS 6.0.1. Click on a link to navigate to that section for further information.

- [SDN connector support on page 3035](#)
- [Tagging NSX VMs from FortiGate on page 3028](#)
- [AWS GuardDuty integration on page 3030](#)
- [HA support for Oracle Cloud Infrastructure on page 3036](#)

What's new in virtual FortiOS 6.0

The following list contains new firewall features added in FortiOS 6.0. Click on a link to navigate to that section for further information.

- [FortiOS On-Demand supported platforms on page 3027](#)
- [NSX credentials encryption on page 3028](#)
- [Certificate validation to NSX manager on page 3028](#)
- [FortiGate VMX license status](#)
- [SDN connector addressing on page 3029](#)
- [Support for KVM-based hypervisor in AWS on page 3029](#)

- [HA support for GCP on page 3034](#)
- [HA support for Azure on page 3032](#)

Virtual FortiOS overview

The following topics are included in this section:

FortiGate VM models and licensing

Fortinet offers the FortiGate VM in five virtual appliance models determined by license. When configuring your FortiGate VM, be sure to configure hardware settings within the ranges outlined below. Contact your Fortinet Authorized Reseller for more information.

FortiGate VM model information

Technical Specification	FG-VM00	FG-VM01	FG-VM02	FG-VM04	FG-VM08	FG-VM16	FG-VM32	FG-VMUL
Virtual CPUs (min / max)	1 / 1	1 / 1	1 / 2	1 / 4	1 / 8	1 / 16	1 / 32	1 / unlimited
Virtual Network Interfaces (min / max)	2 / 10							
Virtual Memory (min / max)	1GB / 2GB	1GB / 2GB	1GB / 4GB	1GB / 6GB	1GB / 12GB	1GB / 24GB	1GB / 48GB	1GB / unlimited GB
Virtual Storage (min / max)	32GB / 2TB							
Managed Wireless APs (tunnel mode / global)	32 / 32	32 / 64	256 / 512	256 / 512	1024 / 4096	1024 / 4096	1024 / 4096	1024 / 4096
Virtual Domains (default / max)	1 / 2	10 / 10	10 / 25	10 / 50	10 / 500	10 / 500	10 / 500	10 / 500

There may be times the min/max values can change. An example for this is when the maximum memory for FG-VM00 changed between 5.2 and 5.4 from 1 GB to 1.5 GB. If that is the case, the settings for the VM will have to be manually changed to accommodate the new parameters.

After placing an order for FortiGate VM, a license registration code is sent to the email address used on the order form. Use the registration number provided to register the FortiGate VM with Customer Service & Support and then download the license file. Once the license file is uploaded to the FortiGate VM and validated, your FortiGate VM appliance is fully functional.

FortiGate VM evaluation license

FortiGate VM includes a limited embedded 15-day trial license that supports:

- 1 CPU maximum
- 1024 MB memory maximum
- low encryption only (no HTTPS administrative access)
- all features except FortiGuard updates

You cannot upgrade the firmware, doing so will lock the Web-based Manager until a license is uploaded. Technical support is not included. The trial period begins the first time you start FortiGate VM. After the trial license expires, functionality is disabled until you upload a license file.

The number of Virtual Network Interfaces is not solely dependent on the FortiGate VM. Some virtual environments have their own limitations on the number of interfaces allowed. As an example, if you go to <https://docs.microsoft.com/en-us/azure/virtual-network/virtual-networks-multiple-nics>, you will find that Azure has its own restrictions for VMs, depending on the type of deployment or even the size of the VM.

Registering FortiGate VM

To obtain the FortiGate VM license file you must first register your FortiGate VM with the [Fortinet Support](#) website.

To register your FortiGate VM:

1. Log in to the Customer Service & Support portal using an existing support account or select **Sign Up** to create a new account.
2. In the main page, under **Asset**, select **Register/Renew**.

The **Registration** page opens.

3. Enter the registration code that was emailed to you and select **Register**. A registration form will display.
4. After completing the form, a registration acknowledgment page will appear.
5. Select the **License File Download** link.
6. You will be prompted to save the license file (`.lic`) to your local computer. See "Upload the license file" for instructions on uploading the license file to your FortiGate VM via the Web-based Manager.

Downloading the FortiGate VM deployment package

FortiGate VM deployment packages are included with FortiGate firmware images on the [Customer Service & Support](#) site. First, see the following table to determine the appropriate VM deployment package for your VM platform.

Selecting the correct FortiGate VM deployment package for your VM platform

VM Platform	FortiGate VM Deployment File
Citrix XenServer v5.6sp2, 6.0 and later	FGT_VM64-v500-buildnnnn-FORTINET.out.CitrixXen.zip

VM Platform	FortiGate VM Deployment File
Open Xen v3.4.3, 4.1	FGT_VM64-v500-buildnnnn-FORTINET.out.OpenXen.zip
Microsoft Hyper-V Server 2008R2 and 2012	FGT_VM64-v500-buildnnnn-FORTINET.out.hyperv.zip
KVM (qemu 0.12.1)	FGT_VM64-v500-buildnnnn-FORTINET.out.kvm.zip
VMware ESX 4.0, 4.1 ESXi 4.0/4.1/5.0/5.1/5.5	FGT_VM32-v500-buildnnnn-FORTINET.out.ovf.zip (32-bit) FGT_VM64-v500-buildnnnn-FORTINET.out.ovf.zip

For more information see the FortiGate product datasheet available on the Fortinet web site, https://www.fortinet.com/content/dam/fortinet/assets/data-sheets/FortiGate_VM.pdf.

The firmware images FTP directory is organized by firmware version, major release, and patch release. The firmware images in the directories follow a specific naming convention and each firmware image is specific to the device model. For example, the FGT_VM32-v500-build0151-FORTINET.out.ovf.zip image found in the v5.0 Patch Release 2 directory is specific to the FortiGate VM 32-bit environment.

You can also download the FortiOS Release Notes, FORTINET-FORTIGATE MIB file, FSSO images, and SSL VPN client in this directory. The Fortinet Core MIB file is located in the main FortiGate v5.00 directory.

To download the FortiGate VM deployment package:

1. In the main page of the Customer Service & Support site, select **Download > Firmware Images**.

The **Firmware Images** page opens.

2. In the **Firmware Images** page, select **FortiGate**.
3. Browse to the appropriate directory on the FTP site for the version that you would like to download.
4. Download the appropriate .zip file for your VM server platform.

You can also download the FortiGate Release Notes.

5. Extract the contents of the deployment package to a new file folder.

Deployment package contents

Citrix XenServer

The FORTINET.out.CitrixXen.zip file contains:

- fortios.vhd: the FortiGate VM system hard disk in VHD format
- fortios.xva: binary file containing virtual hardware configuration settings

- in the ovf folder:
 - FortiGate-VM64.ovf: Open Virtualization Format (OVF) template file, containing virtual hardware settings for Xen
 - fortios.vmdk: the FortiGate VM system hard disk in VMDK format
 - datadrive.vmdk: the FortiGate VM log disk in VMDK format

The ovf folder and its contents is an alternative method of installation to the .xva and VHD disk image.

OpenXEN

The FORTINET.out.OpenXen.zip file contains only fortios.qcow2, the FortiGate VM system hard disk in qcow2 format. You will need to manually:

- create a 32GB log disk
- specify the virtual hardware settings

Microsoft Hyper-V

The FORTINET.out.hyperv.zip file contains:

- in the Virtual Hard Disks folder:
 - fortios.vhd: the FortiGate VM system hard disk in VHD format
 - DATADRIIVE.vhd: the FortiGate VM log disk in VHD format
- In the Virtual Machines folder:
 - fortios.xml: XML file containing virtual hardware configuration settings for Hyper-V. This is compatible with Windows Server 2012.
- Snapshots folder: optionally, Hyper-V stores snapshots of the FortiGate VM state here

KVM

The FORTINET.out.kvm.zip contains only fortios.qcow2, the FortiGate VM system hard disk in qcow2 format. You will need to manually:

- create a 32GB log disk
- specify the virtual hardware settings

VMware ESX/ESXi

You will need to create a 32GB log disk.

The FORTINET.out.ovf.zip file contains:

- fortios.vmdk: the FortiGate VM system hard disk in VMDK format
- datadrive.vmdk: the FortiGate VM log disk in VMDK format
- Open Virtualization Format (OVF) template files:
 - FortiGate-VM64.ovf: OVF template based on Intel e1000 NIC driver
 - FortiGate-VM64.hw04.ovf: OVF template file for older (v3.5) VMware ESX server
 - FortiGate-VMxx.hw07_vmxnet2.ovf: OVF template file for VMware vmxnet2 driver
 - FortiGate-VMxx.hw07_vmxnet3.ovf: OVF template file for VMware vmxnet3 driver

Use the VMXNET3 interface (FortiGate-VMxx.hw07_vmxnet3.ovf template) if the virtual appliance will distribute workload to multiple processor cores.

Deploying the FortiGate VM appliance

Prior to deploying the FortiGate VM appliance, the VM platform must be installed and configured so that it is ready to create virtual machines. The installation instructions for FortiGate VM assume that

- You are familiar with the management software and terminology of your VM platform.
- An Internet connection is available for FortiGate VM to contact FortiGuard to validate its license or, for closed environments, a FortiManager can be contacted to validate the FortiGate VM license. See "Validate the FortiGate VM license with FortiManager".

For assistance in deploying FortiGate VM, refer to the deployment chapter in this guide that corresponds to your VMware environment. You might also need to refer to the documentation provided with your VM server. The deployment chapters are presented as examples because for any particular VM server there are multiple ways to create a virtual machine. There are command line tools, APIs, and even alternative graphical user interface tools.

Before you start your FortiGate VM appliance for the first time, you might need to adjust virtual disk sizes and networking settings. The first time you start FortiGate VM, you will have access only through the console window of your VM server environment. After you configure one FortiGate network interface with an IP address and administrative access, you can access the FortiGate VM web-based manager.

After deployment and license validation, you can upgrade your FortiGate VM appliance's firmware by downloading either FGT_VM32-v500-buildnnnn-FORTINET.out (32-bit) or FGT_VM64-v500-buildnnnn-FORTINET.out (64-bit) firmware. Firmware upgrading on a VM is very similar to upgrading firmware on a hardware FortiGate unit.

FortiGate-VM is not part of the FortiGuard Network for the purpose of upgrades.

Performance and optimization

Performance is improved for FortiOS VM platforms by implementing features to improve efficiency and resource utilization.

Interrupt affinity

You can configure interrupt affinity and packet distribution to optimize performance for your VM environment. Interrupt affinity allows you to align interrupts from interfaces to specific CPUs.

Configuring interrupt affinity

Use the following commands to configure interrupt affinity for two 10G interfaces (port2 and port3).

Interrupts from first interface are assigned to core #0 and those from the second interface are assigned to core #1.

```
config system affinity-interrupt
edit 1
```

```
    set interrupt "port2-TxRx-0"
    set affinity-cpumask "0x1"
next
edit 2
    set interrupt "port2-TxRx-1"
    set affinity-cpumask "0x1"
next
edit 3
    set interrupt "port3-TxRx-0"
    set affinity-cpumask "0x2"
next
edit 4
    set interrupt "port3-TxRx-1"
    set affinity-cpumask "0x2"
end
```

Packet distribution

Packet distribution allows you to configure FortiGate-VM to distribute processing to multiple CPUs. Use the following commands to configure packet redistribution to redistribute packets from core #0 and #1 to all other cores.

Configuring packet distribution

The example is based on VM08:

```
config system affinity-packet-redistribution
edit 1
    set interface "port2"
    set affinity-cpumask "0xFC"
next
edit 2
    set interface "port3"
    set affinity-cpumask "0xFC"
end
```

Other virtual FortiOS products

Just like a VM installed on a platform located on a physical computer, these are instances of the FortiOS firmware installed in virtual environments.

SDN environments

FortiOS-VM is now supported in a Number of SDN (Software Defined Network) environments through the use of a SDN connector. The software can be found on the [Fortinet Service and Support site](#). Documentation can be found on the [Fortinet Documentation site](#) under the product heading of Fortinet Connectors.

The products include:

FortiGate-VMX

Admin guide can be found at <https://docs.fortinet.com/d/fortigate-vmx-install-v.2>.

FortiOS On-Demand

Admin guide can be found at <https://docs.fortinet.com/d/fortigate-fortinetvm-on-demand-administration-guide>.

FortiOS On-Demand supported platforms

Connectors:

FortiADC Connector for Cisco ACI

- Guides found at <https://docs.fortinet.com/fortinet-connectors/admin-guides>.
- Versions available:
 - 1.0.0
 - 1.2.0
 - 1.3.0

FortiADC Connector for Cisco ACI

- Guides found at <https://docs.fortinet.com/fortinet-connectors/admin-guides>.
- Versions available:
 - 1.0.0
 - 1.2.0
 - 1.3.0

FortiGate Connector for HPE VAN SDN

- Guides found at <https://docs.fortinet.com/fortinet-connectors/admin-guides>.
- Versions available:
 - 1.0.5
 - 1.1.0

FortiGate Connector for OpenStack ML2

- Guides found at <https://docs.fortinet.com/fortinet-connectors/admin-guides>.
- Versions available:
 - 1.1

FortiManager Connector for Nuage Networks

- Guides found at <https://docs.fortinet.com/fortinet-connectors/admin-guides>.
- Versions available:
 - 1.0

Fortinet SDN Connector for Nuage VSP

Instruction can be found at <http://cookbook.fortinet.com/nuage-vsp/>

Additional information relating to connectors

While the product documentation concerns itself with the connector software, there is also settings within FortiOS that relates to the usage of those connectors.

NSX connector support

There is support for NSX connector to upgrade to SDN connectors.

Change to config system sdn-connector:

```
config nsx setting
```

Change to config firewall address:

```
set type nsx

set type dynamic
set sdn nsx
```

When using the sdn nsx setting, the user should also use the nsx rest-api password.

Tagging NSX VMs from FortiGate

There is a requirement to have VMs tagged for the use of features such as IP detection. The tagging of VMs in an NSX environment is performed from the FortiGate by using an `execute` command.

The command performs the following functions when run:

- An API call to NSX to find the `vm_id` based on the IP address.
- An API call to resolve the security tag name to `tag_id`
- An API call to add the VM to the security tag

Command syntax:

```
execute sdn tag nsx <ip> <tagname> <enable or disable spoofguard>
```

Option	Description
<code>ip</code>	IP address of the VM
<code>tagname</code>	Name of tag for the VM(s)
<code>enable or disable spoofguard</code>	<ul style="list-style-type: none">• 1 is used to enable SpoofGuard• 0 is used to disable SpoofGuard

NSX credentials encryption

NSX requires AES256 as a minimum level of encryption. The credentials for NSX are stored using AES256 encryption in preparation for being transmitted over the network for NSX authentication.

Certificate validation to NSX manager

The first time FortiGate-SVM connects to the NSX Manager (when a **Service Manager** is added), you can save the service manager's certificate as a fingerprint in the FortiGate configuration. After this is done, the FortiGate-SVM can validate the connection by matching the certificate of the NSX Manager against the saved fingerprint in the configuration every time that:

- the FortiGate-SVM connects to the NSX Manager
- the NSX Manager connects to the FortiGate-SVM

CLI settings:

This setting is available only in the CLI.

```
config system sdn-connector
edit <connector-name>
set type nsx
set nsx-cert-fingerprint <string value>
end
```

`nsx-cert-fingerprint` is a hidden entry. If you are in the `nsx` context and type the command `set ?` to get a listing of the available options, it will not show up.

Removal of fingerprint

If the NSX Manager service is deleted from the FortiGate-SVM, to avoid potential security issues, the fingerprint is automatically deleted.

SDN connector addressing

When setting the address for an SDN connection, the value can be a fully qualified domain name (FQDN) as well as an IP address. The setting that is currently called `server` was once called `server-ip`.

CLI

```
config system sdn-connector
edit <example>
set server [<ip address>|<fqdn address>]
end
```

Public cloud environments

Unlike SDNs where the user has administrative control over the virtual environment that the FortiOS is being placed into, the Public Cloud services are run and managed by 3rd party companies with their own methods and rules of provisioning that need to be followed to install the firmware into the environment.

Amazon Web Services (AWS)

Online documentation can be found at <http://cookbook.fortinet.com/amazon-web-services-aws/>

Additional information for AWS

While the online documentation is primarily for the installation of the FortiOS into the virtual environment, periodically improvements are made to the firmware that affects its interaction with the environment but isn't really covered by installation instructions or information has changed in regards to those instructions but they may not have all been updated yet.

Support for KVM-based hypervisor in AWS

FortiGate-VM can be provisioned in AWS C5 instances on the marketplace (BYOL/OnDemand). These instances are based on a home-brewed version of KVM that AWS started using. Systems deployed in C5 will see better

performance compared to C3/C4 instances. Deploying FortiGate-VM in these instances requires no configuration on the part of the user.

FortiGate-VM firmware can be placed in these instances because of:

- An NVME driver that is required to run C5 instances. It gets the correct partition name dependencies if an NVME device is being used.
- Removing the `xenstore` checking requirement in the AWS setup daemon that is not required in non-Xen based instances.

HA

AWS supports the use of HA.

This includes two parts:

1. HA with unicast heartbeat traffic.
2. AWS API supports to move secondary IPs and update routing tables.

CLI:

Unicast HA config

```
config system ha
    unicast-hb {enable|disable}
    unicast-hb-peerip <Unicast Heartbeat Peer IP>
end
```

SDN connector - AWS

Improvements have been made in the support of FortiGate-VM integrating into the AWS environment.

1. `config aws setting` has been moved to the context of `config system sdn-connector`.

```
config system sdn-connector
    edit <string>
        set access-key <AWS access key ID>
        set secret-key <AWS secret access key>
        set region <AWS region name>
        set vpc-id <AWS VPC ID>
    end
```
2. Update to the GUI SDN connector edit page that supports allowing configuration of the following fields:
 - AWS access key ID
 - AWS secret access key
 - AWS region name
 - AWS VPC ID
 - Update Interval
3. Change to address edit page to allow configuration of the **Filter** field for Dynamic AWS address.
4. Update to the dynamic address monitor API to get resolved address list for dynamic AWS addresses.

AWS GuardDuty integration

AWS GuardDuty is a managed threat detection service that monitors malicious or unauthorized behaviors/activities related to AWS resources. GuardDuty provides visibility of logs called findings, and Fortinet

provides a Lambda script that populates a list of malicious IP addresses then stores it in an S3 location. FortiGate can then be configured to point to the location as the external feed of threat vectors.

To use this feature, you must subscribe to GuardDuty, CloudWatch, and S3.

Fortinet-provided Lambda scripts are not supported within regular Fortinet technical support scope. For questions related to the scripts, contact awssales@fortinet.com.

GuardDuty findings give visibility on the following:

- **Severity:** High/medium/low (associated with scores)
- **Where it occurred:** Region, resource ID, account ID
- **When:** Last seen date/time
- Count
- **Detailed information can include:**
 - **Affected resource:** type/instance ID/image ID/port/resource type/image description/launch time/tags/network interfaces (public IP, private IP, subnet ID, VPCID, security groups)
 - **Action:** type/connection direction
 - Actor
 - Additional information

To configure the integration:

- Subscribe and enable GuardDuty on AWS. When findings occur, they are pushed to CloudWatch.
- CloudWatch events trigger the Lambda script for automated actions.
- If one of the following criteria is met:
 - Connected direction is inbound, the finding contains an IP address, and the severity is greater than the minimum score (configurable)
 - Connected direction is unknown, the finding contains an IP address and matches certain known threat lists (such as ProofPoint) that GuardDuty identifies, and the severity is greater than the minimum score

The IP address is considered black and is appended to a file located in the S3 bucket/directory.

- FortiGate queries the file as the external source of blacklisted IP addresses. The following is an example configuration:

Edit External Resource

Type: FortiGuard Category | **Firewall IP Address** | Domain Name

Name: GuardDuty

URI of external resource: https://s3.us-east-2.amazonaws.com/ip

Refresh Rate: 5

Comments: 0/255

Last Update: Not updated

Status: ☒

OK Cancel

The configuration can be done in the CLI as follows:

```
config system external-resource
  edit "GuardDuty"
    set type address
    set resource "https://s3.us-east-2.amazonaws.com/ip-blacklist/ip.txt"
  next
end
```

You can then use the gathered IP addresses as criteria to protect the network.

Azure

HA support for Azure

FortiOS supports the use of active/passive HA, similar to that for Amazon Web Services (AWS) in an Azure environment.

New CLI options are available to configure with Azure:

- The `system sdn-connector` contains a connector type for Azure environments called `azure`.
- The `nic` option enables you to configure the Azure network interface.
- The `route-table` option enables you to configure the Azure route table.

Example:

```
config system sdn-connector
  edit "azd"
    set type azure
  config nic
    edit nic-eth2
      config ip
        edit ipconfig1
          set public-ip p3
        next
      end
    next
  edit nic-eth3
    config ip
```

```

        edit ipconfig1
            set public-ip p2
        next
    end
next
end
config route-table
    edit 1
        config route
            edit 12
                set next-hop 111.233.222.233
            next
        end
    next
end

```

In addition to the options for HA already specified, there are settings specific to Azure connectivity within the `system sdn-connector` context once the `type` has been set to `azure`.

Option	Description
tenant-id	Azure tenant ID (directory ID).
subscription-id	Azure subscription ID.
client-id	Azure client ID (application ID).
client-secret	Azure client secret (application key).
resource-group	Azure resource group.
azure-region	Global/China Azure Region.
update-interval	Dynamic object update interval in seconds (0 - 3600, 0 means disabled, default = 60).

Online documentation can be found at <http://cookbook.fortinet.com/microsoft-azure/>

Google Cloud Platform (GCP)

The following FortiGate-VM models will be supported on Google Cloud Platform:

- FG-VM01
- FG-VM02
- FG-VM04
- FG-VM08

FG-WM00 is not supported.

Since GCP use netmask 32, static route must be configured on GCP VPC, instead of FGT.

Licenses will be interchangeable between platforms. A FG-VM04 license that functions in a VMware or Citrix environment can be also used in the GCP environment as well.

While an .out file will be necessary for upgrading, full downloadable images will not be needed for initial installation of the solution. GCP consists of preexisting images that can be checked out of their library and deployed instantly. A difference between this environment and enterprise virtualization platforms is that machine size can never change. An n1-standard-4 has exactly 15 GB of RAM and 4 vCPUs. This can never be changed or edited by the end user or administrator.

The currently available GCP instances we are looking to support are as follows (these will/could change as vNIC values reveal themselves):

FG-VM	Equates to Instance Type	vCPU	RAM	Disks
FG-VM01-GC	n1-standard-1	1	3.75GB	16 (32 in Beta)
FG-VM02-GC	n1-standard-2	2	7.50 GB	16 (64 in Beta)
FG-VM04-GC	n1-standard-4	4	15 GB	16 (64 in Beta)
FG-VM08-GC	n1-standard-8	8	30 GB	16 (128 in Beta)
FG-VM16-GC	n1-standard-16	16	60 GB	16 (128 in Beta)
FG-VM32-GC	n1-standard-32	32	88 GB	16 (128 in Beta)
FG-VMUL-GC	any of the above and any new that could be created.			

Additional information from GCP: <https://cloud.google.com/compute/docs/images/building-custom-os>.

HA support for GCP

FortiOS supports the use of active/passive HA, using a unicast heartbeat, in Google Cloud Platform (GCP) similar to the HA support for Amazon Web Services (AWS).

This support includes:

- HA in the same region within a project
- HA session and configuration synchronization
- Automatic failover to the passive unit (time dependent on configuration), using the built-in API call to GCP for changing the routing path from the active unit to the passive unit.

There is a new connector type, `gcp`, that has been added to the `type` option for `system sdn-connector` as well as a setting for the mask of the unicast heartbeat in `system ha`.

GCP type example:

```
config system sdn-connector
  edit gcp
    set type gcp
  config external-ip
    edit gundam-public
  next
```

```

        end
    config route
        edit gundam-route
        next
    end
next
end

```

Unicast example:

```

config system ha
    set group-id 20
    set group-name "cluster1"
    set mode a-p
    set hbdev "port3" 50
    set ha-mgmt-status enable
    config ha-mgmt-interfaces
        edit 1
            set interface "port4"
            set gateway 172.16.100.1
        next
    end
    set override disable
    set priority 20
    set unicast-hb enable
    set unicast-hb-peerip 172.16.201.3
    set unicast-hb-netmask 255.255.255.0
end

```

Oracle Cloud Infrastructure (OCI)

SDN connector support

Support has been added to enable SDN connector support for FortiGate in Oracle Cloud Infrastructure. This connector makes calls to the OCI API to get information about VMs running in the OCI cloud.

The connector is configured by using the commands:

```

config sys sdn
    edit <name of sdn controller>
        set status enable
        set type oci
        set tenant-id <id>
        set user-id <user id>
        set compartment-id <compartment id>
        set oci-region <OCI server region>
        set oci-cert <OCI certificate>
        set update-interval <interval time>
        set filter <filter argument>
    end

```

The following OCI filters are supported:

- vm_name=<vm name>
- instance_id=<instance id>
- tag.<key>=<value>
- definedtag.<namespace>.<key>=<value>

The values for the filters can have spaces in them as long as the value is inclosed with quotation marks.

HA support for Oracle Cloud Infrastructure

Oracle Cloud Infrastructure (OCI) supports HA for FortiGate-VM. This support does not apply to OCI-Classical or Oracle Public Cloud (OPC).

OCI supports the use of a secondary IP on the virtual network interface (VNIC). This secondary IP is used as the IP of the FortiGate interface instead of the primary IP address, as well as the next hop in the route. When an HA failover occurs, the secondary IP address on the VNIC is changed from master to slave so that the forwarded traffic can go through the new master.

Deployment example – VMware

Once you have downloaded the FGT_VMxx-v5-build0xxx-FORTINET.out.ovf file from <http://support.fortinet.com> and extracted the package contents to a folder on your local computer, you can use the vSphere client to create the virtual machine from the deployment package OVF template.

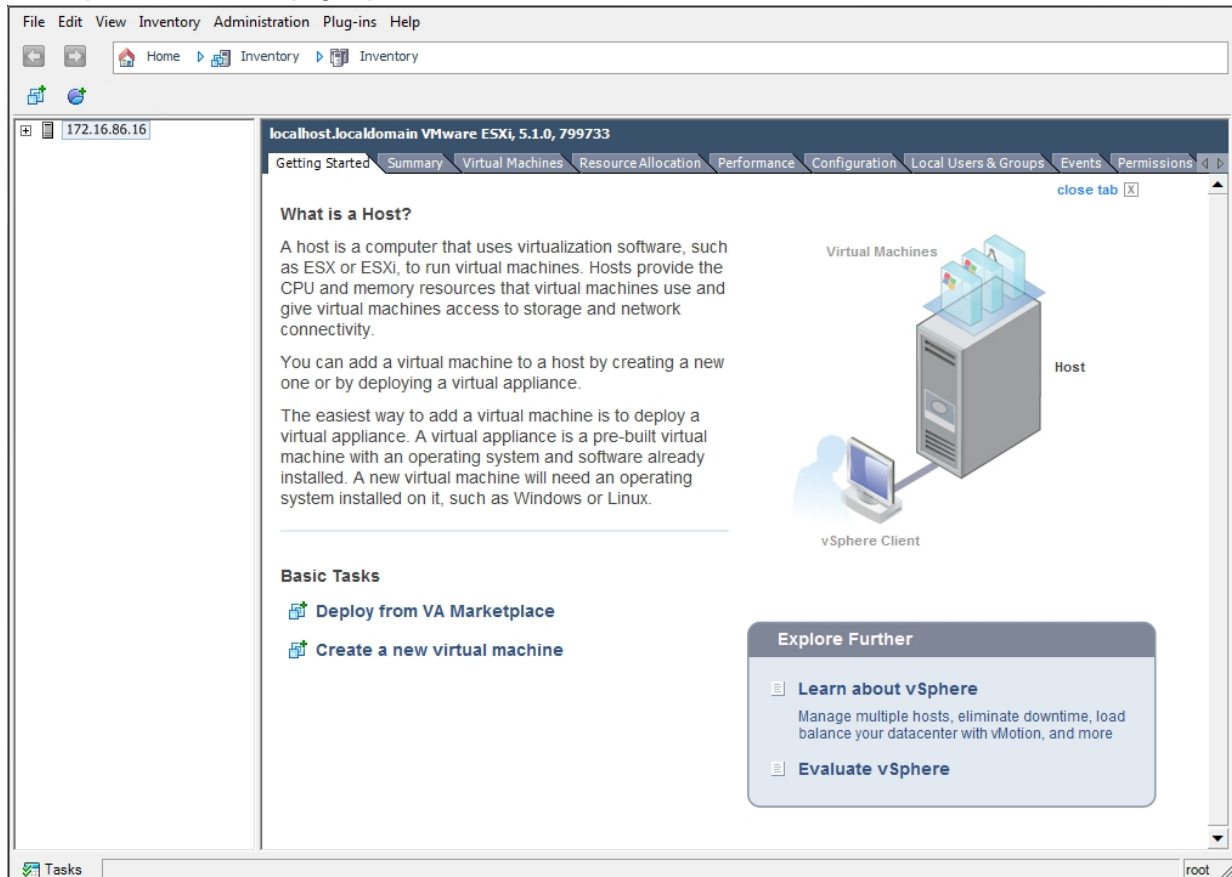

The following topics are included in this section:

Open the FortiGate VM OVF file with the vSphere client

To deploy the FortiGate VM OVF template:

1. Launch the VMware vSphere client, enter the IP address or host name of your server, enter your user name and password and select **Login**.

The vSphere client home page opens.

2. Select **File > Deploy OVF Template** to launch the OVF Template wizard.

The OVF Template **Source** page opens.

3. Select the source location of the OVF file. Select **Browse** and locate the OVF file on your computer. Select **Next** to continue.

The OVF Template **Details** page opens.

7. Select one of the following:
 - **Thick Provision Lazy Zeroed:** Allocates the disk space statically (no other volumes can take the space), but does not write zeros to the blocks until the first write takes place to that block during runtime (which includes a full disk format).
 - **Thick Provision Eager Zeroed:** Allocates the disk space statically (no other volumes can take the space), and writes zeros to all the blocks.
 - **Thin Provision:** Allocates the disk space only when a write occurs to a block, but the total volume size is reported by VMFS to the OS. Other volumes can take the remaining space. This allows you to float space between your servers, and expand your storage when your size monitoring indicates there is a problem. Note that once a Thin Provisioned block is allocated, it remains on the volume regardless if you have deleted data, etc.
8. Select **Next** to continue.

The OVF Template **Network Mapping** page opens.

Description:
The VM Network network

Warning: Multiple source networks are mapped to the host network: VM Network

[Help](#) [< Back](#) [Next >](#) [Cancel](#)

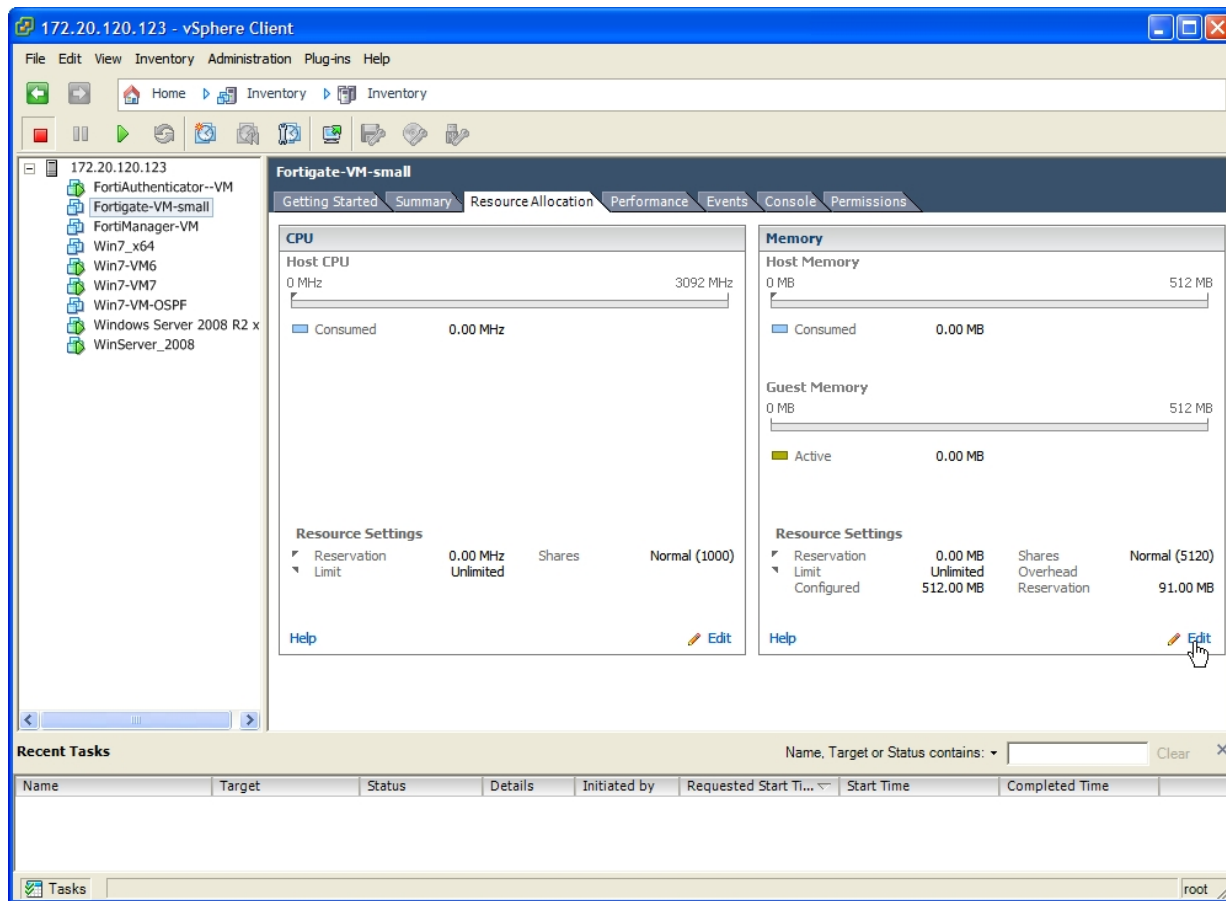

- Map the networks used in this OVF template to networks in your inventory. Network 1 maps to port1 of the FortiGate VM. You must set the destination network for this entry to access the device console. Select **Next** to continue.

The OVF Template **Ready to Complete** page opens.

- Review the template configuration. Make sure that **Power on after deployment** is not enabled. You might need to configure the FortiGate VM hardware settings prior to powering on the FortiGate VM.
- Select **Finish** to deploy the OVF template. You will receive a **Deployment Completed Successfully** dialog box once the FortiGate VM OVF template wizard has finished.

Configure FortiGate VM hardware settings

Before powering on your FortiGate VM you must configure the virtual memory, virtual CPU, and virtual disk configuration to match your FortiGate VM license.

Transparent mode VMware configuration

If you want to use your FortiGate-VM in transparent mode, your VMware server's virtual switches must operate in promiscuous mode. This permits these interfaces to receive traffic that will pass through the FortiGate unit but was not addressed to the FortiGate unit.

In VMware, promiscuous mode must be explicitly enabled:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of vSwitch0.
4. In the **Properties** window left pane, select **vSwitch** and then select **Edit**.
5. Select the **Security** tab, set **Promiscuous Mode** to **Accept**, then select **OK**.
6. Select **Close**.
7. Repeat steps 3 through 6 for other vSwitches that your transparent mode FortiGate-VM uses.

High availability VMware configuration

If you want to combine two or more FortiGate-VM instances into a FortiGate Clustering Protocol (FGCP) High Availability (HA) cluster the VMware server's virtual switches used to connect the heartbeat interfaces must operate in promiscuous mode. This permits HA heartbeat communication between the heartbeat interfaces. HA

heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8890. The FGCP uses link-local IPv4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

To enable promiscuous mode in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect heartbeat interfaces.
4. In the **Properties** window left pane, select **vSwitch** and then select **Edit**.
5. Select the **Security** tab, set **Promiscuous Mode** to **Accept**, then select **OK**.
6. Select **Close**.

You must also set the virtual switches connected to other FortiGate interfaces to allow MAC address changes and to accept forged transmits. This is required because the FGCP sets virtual MAC addresses for all FortiGate interfaces and the same interfaces on the different VM instances in the cluster will have the same virtual MAC addresses.

To make the required changes in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect FortiGate VM interfaces.
4. Set **MAC Address Changes** to **Accept**.
5. Set **Forged Transmits** to **Accept**.

Power on your FortiGate VM

You can now proceed to power on your FortiGate VM. There are several ways to do this:

- Select the name of the FortiGate VM you deployed in the inventory list and select **Power on the virtual machine** in the **Getting Started** tab.
- In the inventory list, right-click the name of the FortiGate VM you deployed, and select **Power > Power On**.
- Select the name of the FortiGate VM you deployed in the inventory list. Click the **Power On** button on the toolbar.

Select the Console tab to view the console. To enter text, you must click in the console pane. The mouse is then captured and cannot leave the console screen. As the FortiGate console is text-only, no mouse pointer is visible. To release the mouse, press Ctrl-Alt.

Deployment example – MS Hyper-V

Once you have downloaded the FGT_VMxx_HV-v5-build0xxx-FORTINET.out.hyperv.zip file and extracted the package contents to a folder on your Microsoft server, you can deploy the VHD package to your Microsoft Hyper-V environment.

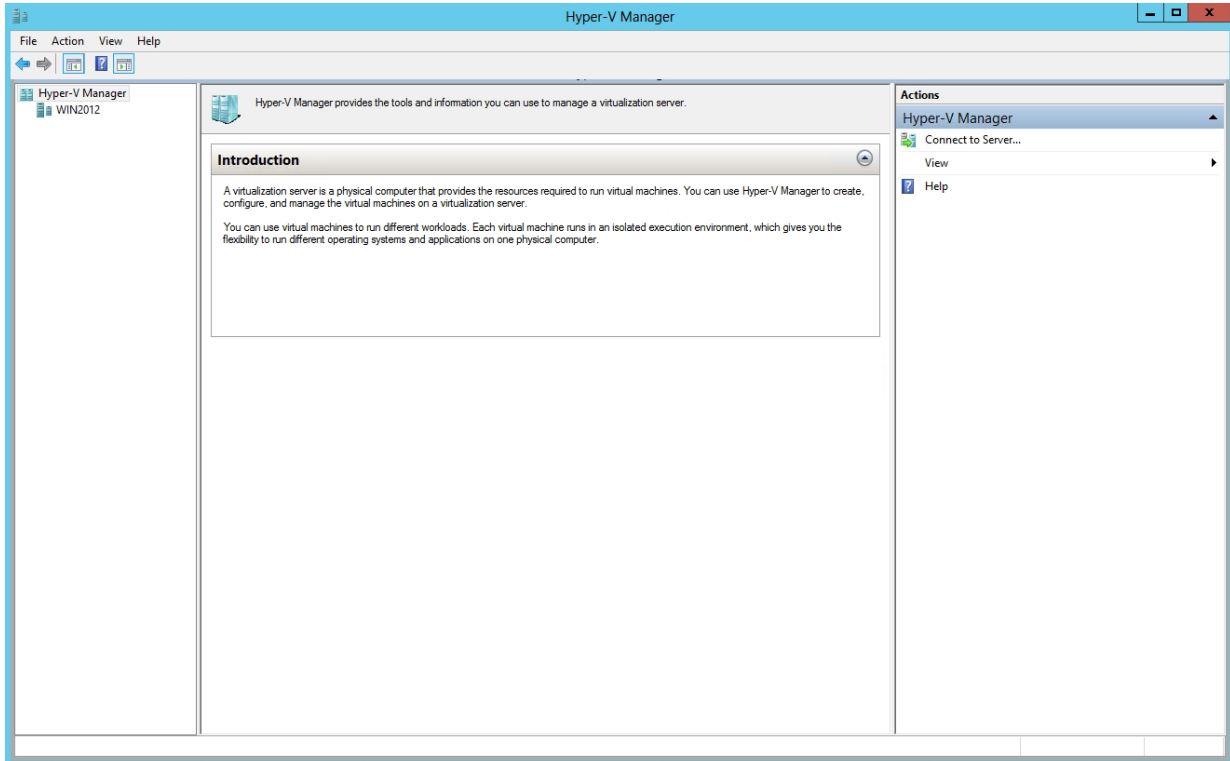

The following topics are included in this section:

Create the FortiGate VM virtual machine

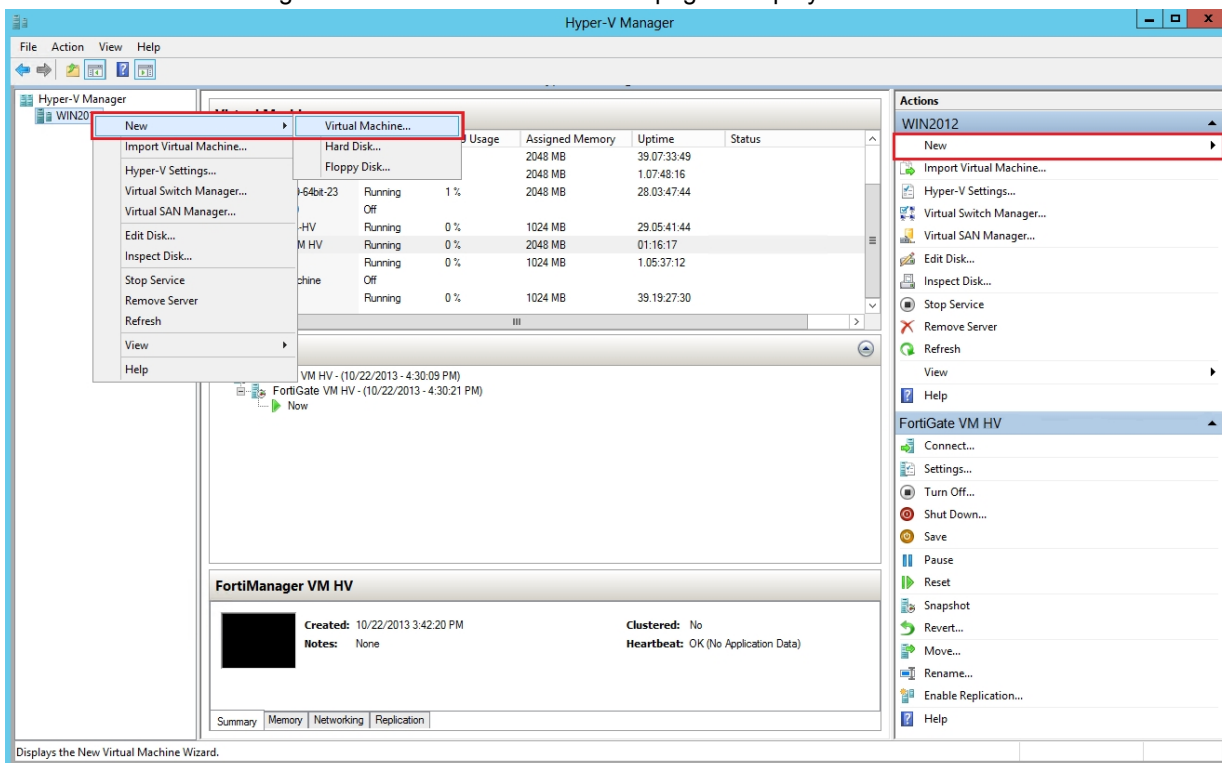

To create the FortiGate VM virtual machine:

1. Launch the Hyper-V Manager in your Microsoft server.

The **Hyper-V Manager** home page opens.

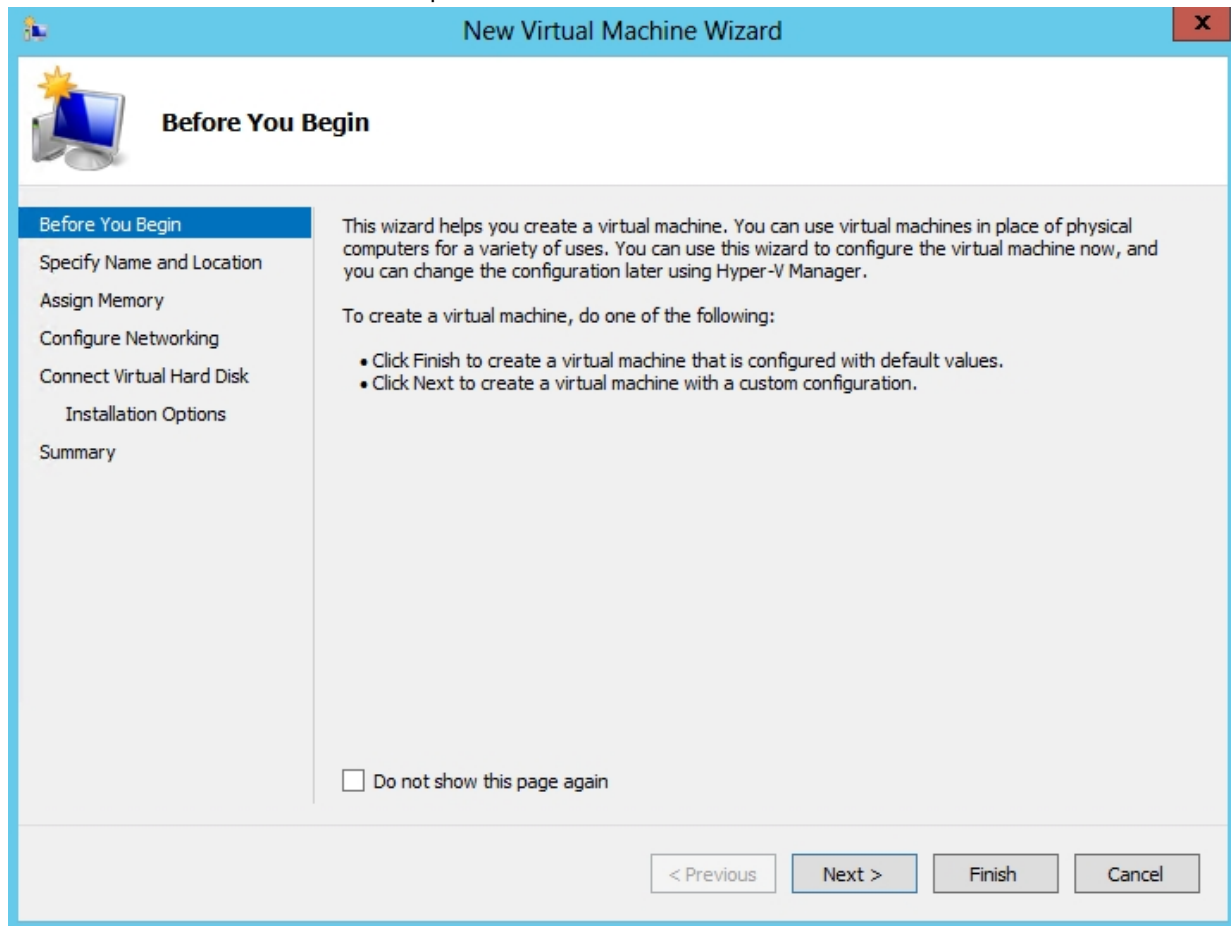

2. Select the server in the right-tree menu. The server details page is displayed.

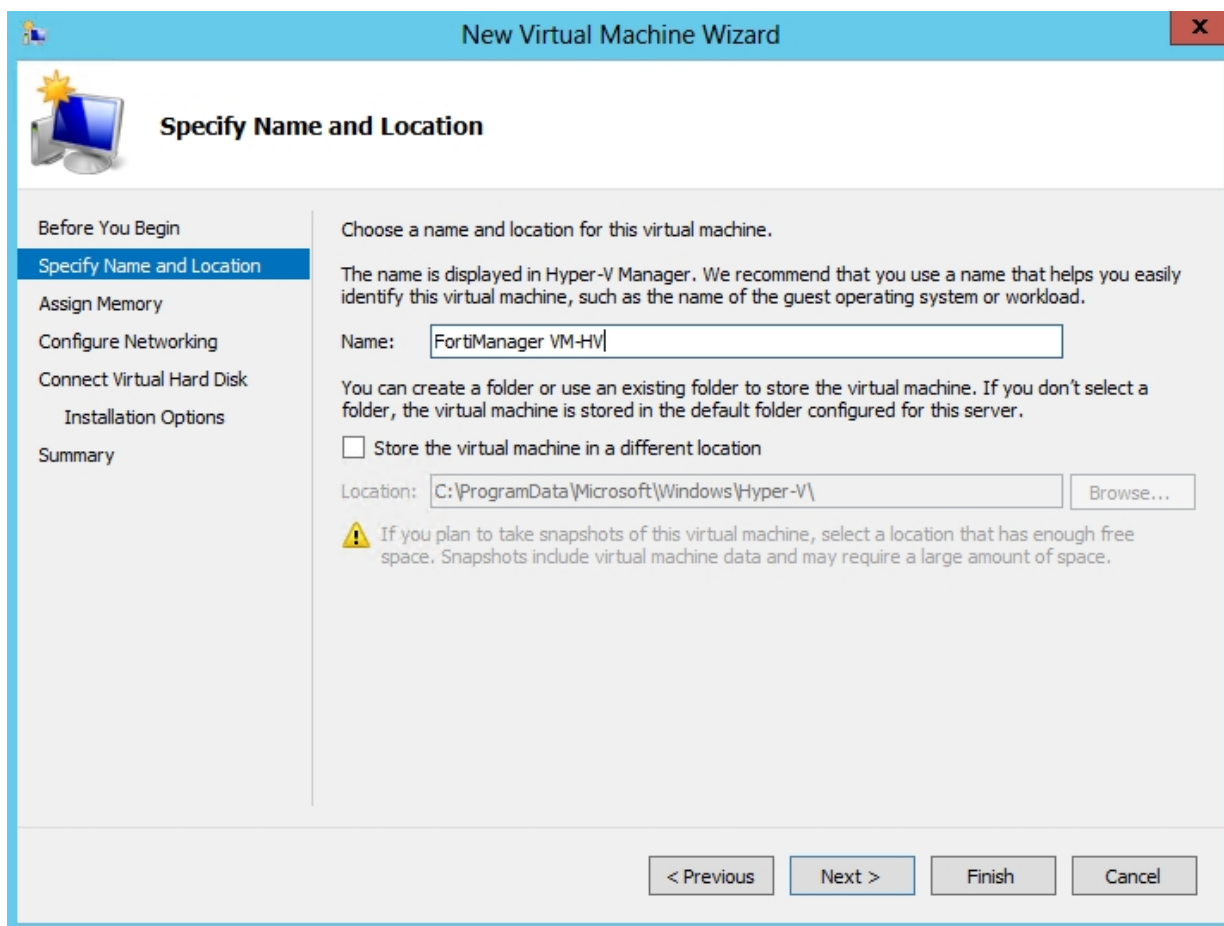

3. Right-click the server and select **New** and select **Virtual Machine** from the menu. Optionally, in the **Actions** menu, select **New** and select **Virtual Machine** from the menu.

The **New Virtual Machine Wizard** opens.

4. Select **Next** to create a virtual machine with a custom configuration.

The **Specify Name and Location** page is displayed.

The screenshot shows the 'New Virtual Machine Wizard' window with the 'Specify Name and Location' step selected in the left-hand navigation pane. The main area contains instructions for naming and locating the virtual machine. The 'Name' field is populated with 'FortiManager VM-HV'. The 'Location' field shows the default path 'C:\ProgramData\Microsoft\Windows\Hyper-V\'. A warning icon and text advise selecting a location with sufficient free space for snapshots. Navigation buttons at the bottom include '< Previous', 'Next >', 'Finish', and 'Cancel'.

New Virtual Machine Wizard

Specify Name and Location

Before You Begin
Specify Name and Location

Configure Networking
Connect Virtual Hard Disk
Installation Options
Summary

Choose a name and location for this virtual machine.

The name is displayed in Hyper-V Manager. We recommend that you use a name that helps you easily identify this virtual machine, such as the name of the guest operating system or workload.

Name:

You can create a folder or use an existing folder to store the virtual machine. If you don't select a folder, the virtual machine is stored in the default folder configured for this server.

☐ Store the virtual machine in a different location

Location:

 If you plan to take snapshots of this virtual machine, select a location that has enough free space. Snapshots include virtual machine data and may require a large amount of space.

< Previous Next > Finish Cancel

5. Enter a name for this virtual machine. The name is displayed in the Hyper-V Manager.

Select **Next** to continue. The **Assign Memory** page is displayed.

New Virtual Machine Wizard

Assign Memory

Before You Begin
Specify Name and Location
Assign Memory
Configure Networking
Connect Virtual Hard Disk
Installation Options
Summary

Specify the amount of memory to allocate to this virtual machine. You can specify an amount from 8 MB through 14100 MB. To improve performance, specify more than the minimum amount recommended for the operating system.

Startup memory: MB

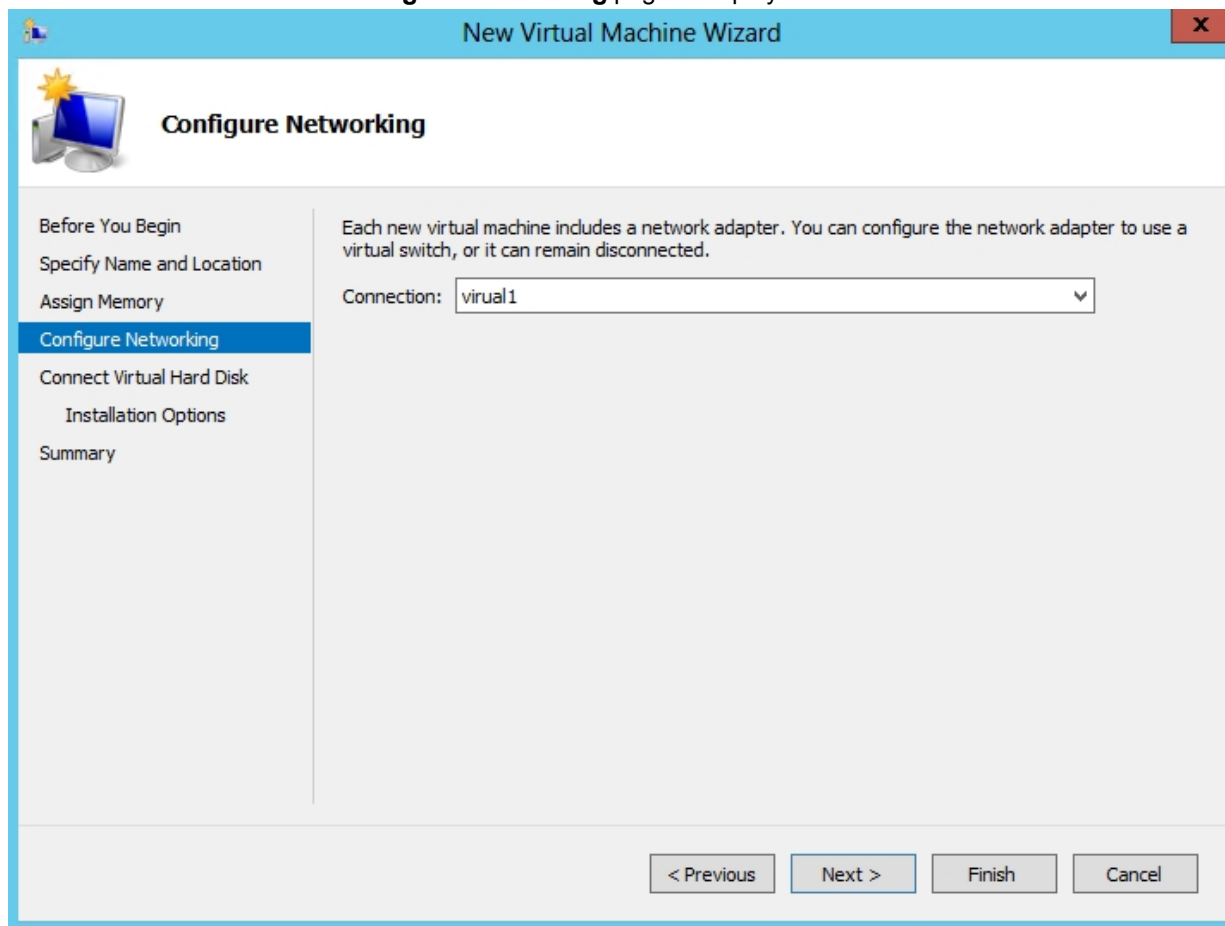

☐ Use Dynamic Memory for this virtual machine.

i When you decide how much memory to assign to a virtual machine, consider how you intend to use the virtual machine and the operating system that it will run.

< Previous Next > Finish Cancel

6. Specify the amount of memory to allocate to this virtual machine. The default memory for FortiGate VM is 1GB (1024MB).

Select **Next** to continue. The **Configure Networking** page is displayed.

7. Each new virtual machine includes a network adapter. You can configure the network adapter to use a virtual switch, or it can remain disconnected. FortiGate VM requires four network adapters. You must configure network adapters in the **Settings** page.

Select **Next** to continue. The **Connect Virtual Hard Disk** page is displayed.

New Virtual Machine Wizard

Connect Virtual Hard Disk

Before You Begin
Specify Name and Location
Assign Memory
Configure Networking
Connect Virtual Hard Disk
Summary

A virtual machine requires storage so that you can install an operating system. You can specify the storage now or configure it later by modifying the virtual machine's properties.

☐ Create a virtual hard disk
Use this option to create a dynamically expanding virtual hard disk with the default format (VHDX).

Name:
Location:
Size: GB (Maximum: 64 TB)

☒ Use an existing virtual hard disk
Use this option to attach an existing virtual hard disk, either VHD or VHDX format.

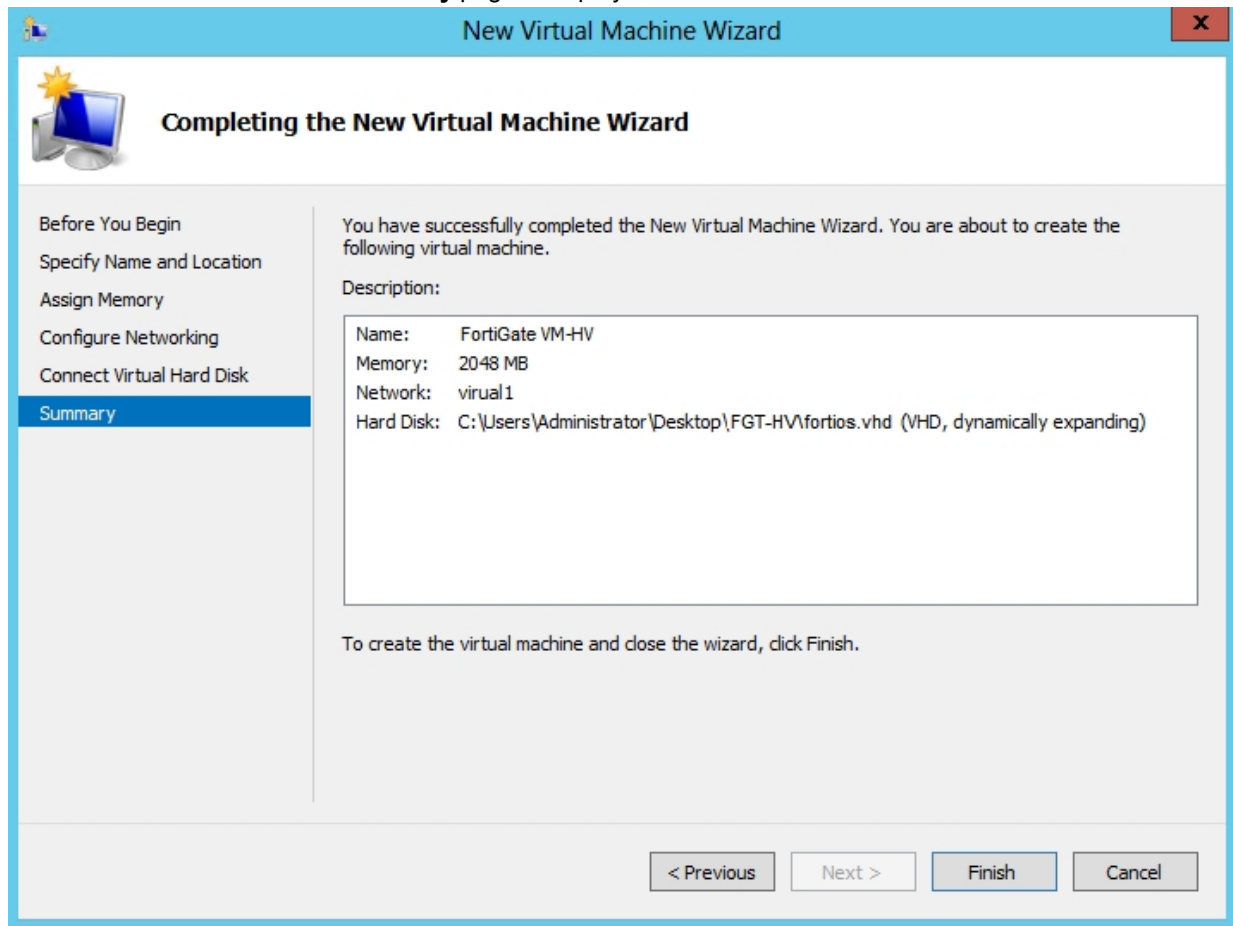

Location:

☐ Attach a virtual hard disk later
Use this option to skip this step now and attach an existing virtual hard disk later.

< Previous Next > Finish Cancel

8. Select to use an existing virtual hard disk and browse for the `fortios.vhd` file that you downloaded from the [Fortinet Customer Service & Support](#) portal.

Select **Next** to continue. The **Summary** page is displayed.

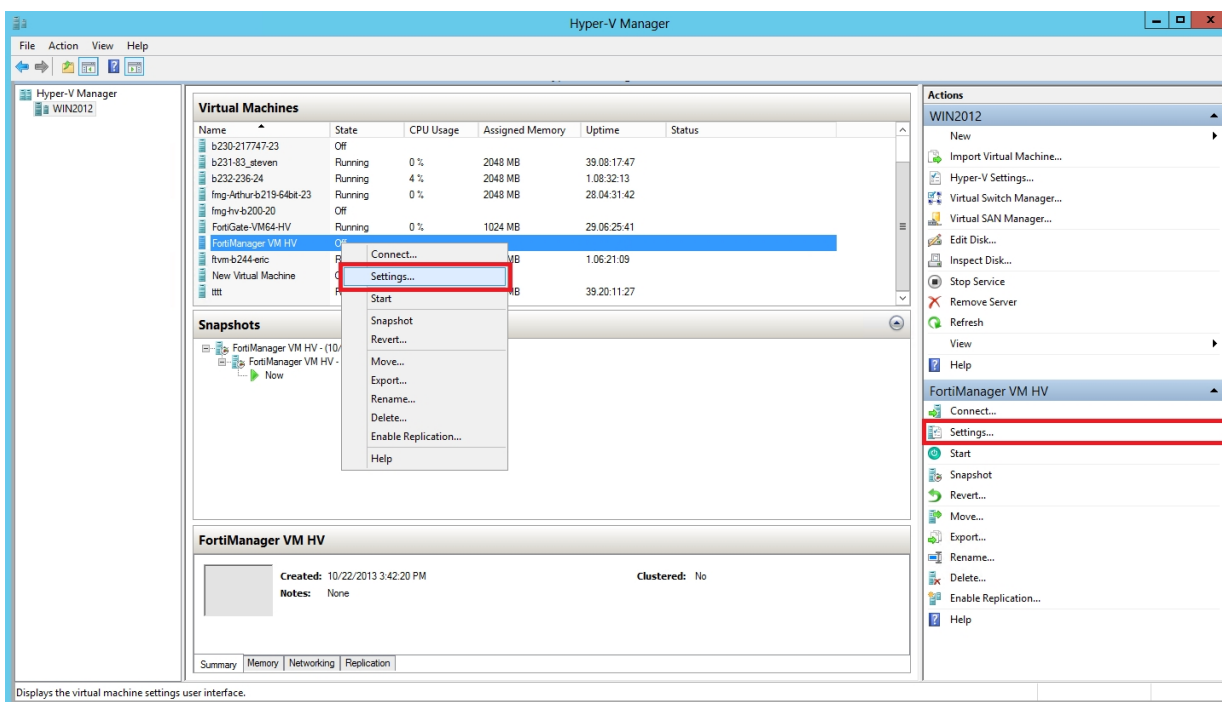

9. To create the virtual machine and close the wizard, select **Finish**.

Configure FortiGate VM hardware settings

Before powering on your FortiGate VM you must configure the virtual memory, virtual CPU, and virtual disk configuration to match your FortiGate VM license.

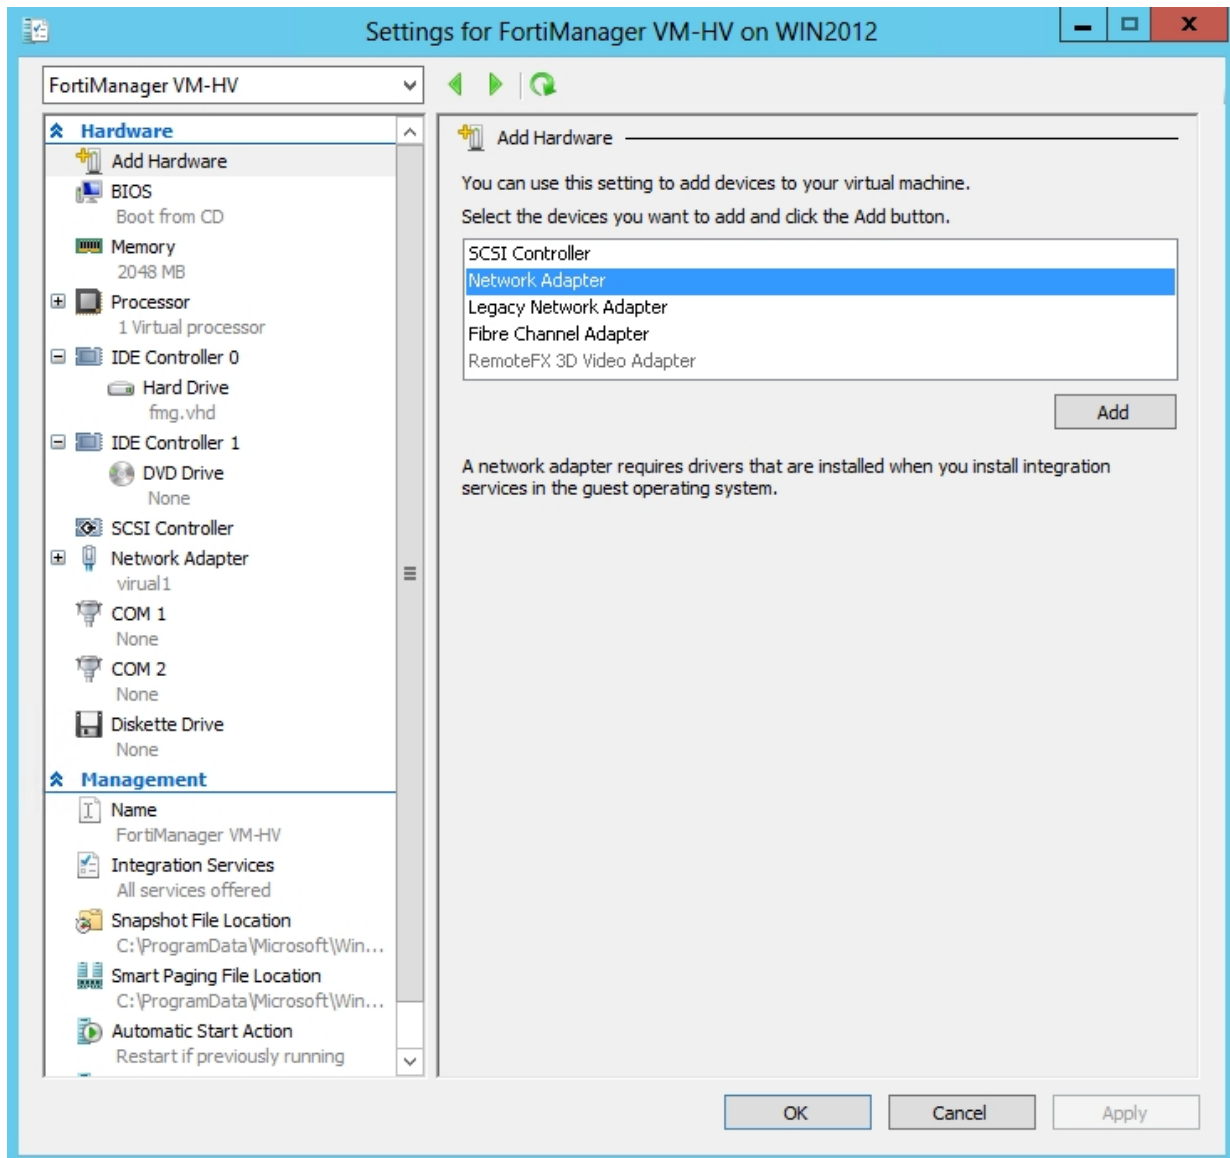

To configure settings for FortiGate VM on the server:

1. In the Hyper-V Manager, locate the name of the virtual machine, right-click the entry, and select **Settings** from the menu. Optionally, you can select the virtual machine and select **Settings** in the **Actions** menu.

Displays the virtual machine settings user interface.

The **Settings** page is displayed.

2. Configure virtual processors, network adapters, and virtual hard drive settings.
3. Select **Apply** to save the settings and then select **OK** to close the settings page.

FortiGate VM virtual processors

You must configure FortiGate VM virtual processors in the server settings page. The number of processors is dependent on your server environment.

Configure FortiGate VM virtual processors:

1. In the **Settings** page, select **Processor** from the **Hardware** menu.

The **Processor** page is displayed.

Processor

You can modify the number of virtual processors based on the number of processors on the physical computer. You can also modify other resource control settings.

Number of virtual processors:

Resource control

You can use resource controls to balance resources among virtual machines.

Virtual machine reserve (percentage):

Percent of total system resources:

Virtual machine limit (percentage):

Percent of total system resources:

Relative weight:

2. Configure the number of virtual processors for the FortiGate VM virtual machine. Optionally, you can use resource controls to balance resources among virtual machines.
3. Select **Apply** to save the settings.

FortiGate VM network adapters

You must configure FortiGate VM network adapters in the server settings page. FortiGate VM supports four network adapters.

Configure FortiGate VM network adapters:

1. In the **Settings** page, select **Add Hardware** from the **Hardware** menu, select **Network Adapter** in the device list, and select the **Add** button.

The **Network Adapter** page is displayed.

The screenshot shows the 'Network Adapter' configuration page. At the top, it says 'Specify the configuration of the network adapter or remove the network adapter.' Below this, the 'Virtual switch:' is set to 'Broadcom NetXtreme Gigabit Ethernet - Virtual Switch'. The 'VLAN ID' section has an unchecked checkbox for 'Enable virtual LAN identification' and a text box containing the value '2'. The 'Bandwidth Management' section also has an unchecked checkbox for 'Enable bandwidth management'. Below this, 'Minimum bandwidth:' and 'Maximum bandwidth:' are both set to '0 Mbps'. A note states: 'To leave the minimum or maximum unrestricted, specify 0 as the value.' At the bottom, there is a 'Remove' button and a warning icon with text: 'Use a legacy network adapter instead of this network adapter to perform a network-based installation of the guest operating system or when integration services are not installed in the guest operating system.'

1. You must manually configure four network adapters for FortiGate VM in the settings page. For each network adapter, select the virtual switch from the drop-down list.
2. Select **Apply** to save the settings.

FortiGate VM virtual hard disk

You must configure the FortiGate VM virtual hard disk in the server settings page.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

Configure a FortiGate VM virtual hard drive:

1. In the **Settings** page, select **IDE Controller 0 > Hard Drive** from the **Hardware** menu.

The **Hard Drive** page is displayed.

 **Hard Drive**

You can change how this virtual hard disk is attached to the virtual machine. If an operating system is installed on this disk, changing the attachment might prevent the virtual machine from starting.

Controller: Location:

Media

You can compact or convert a virtual hard disk by editing the associated file. Specify the full path to the file.

☒ Virtual hard disk:

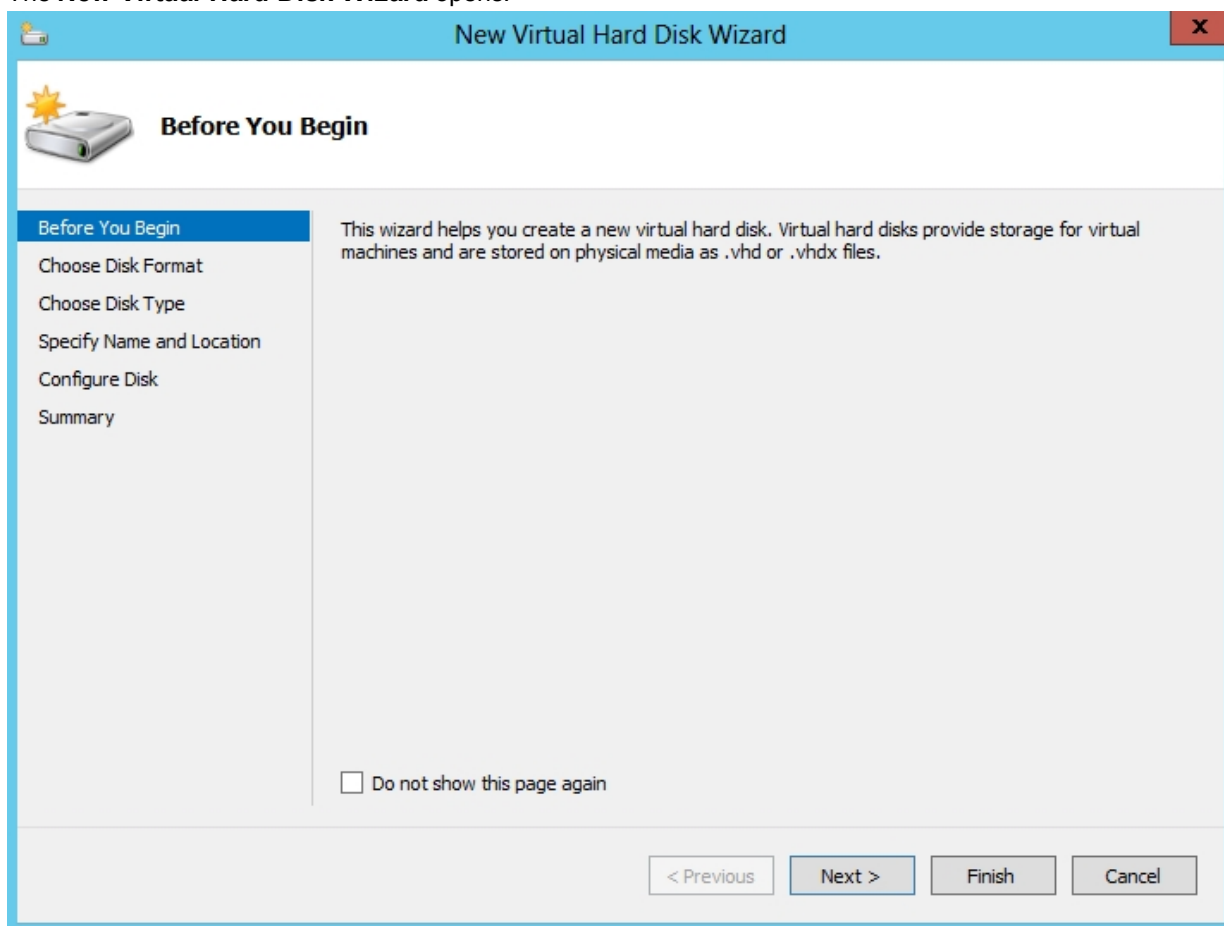

☐ Physical hard disk:

 If the physical hard disk you want to use is not listed, make sure that the disk is offline. Use Disk Management on the physical computer to manage physical hard disks.

To remove the virtual hard disk, click Remove. This disconnects the disk but does not delete the associated file.

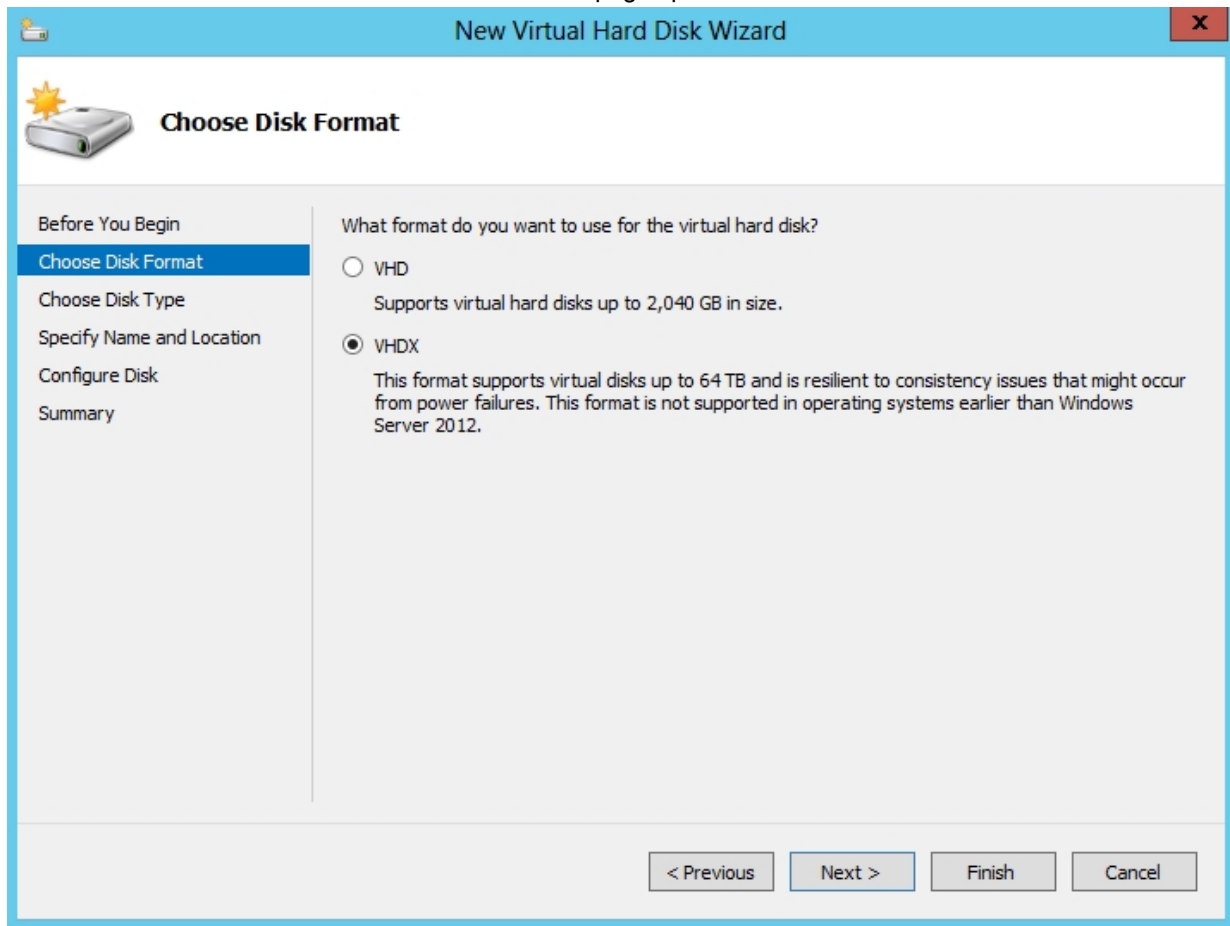

2. Select **New** to create a new virtual hard disk.

The **New Virtual Hard Disk Wizard** opens.

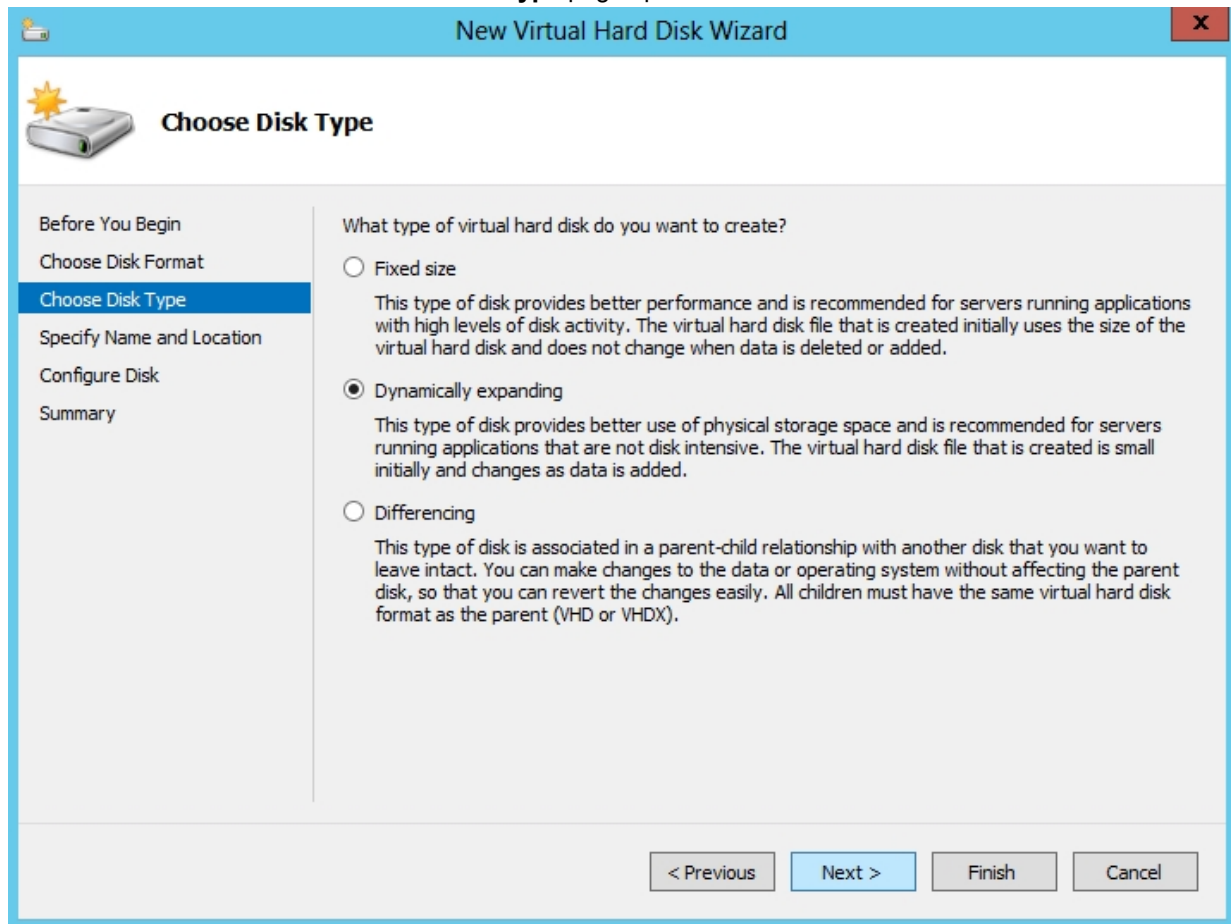

3. This wizard helps you to create a new virtual hard disk.

Select **Next** to continue. The **Choose Disk Format** page opens.

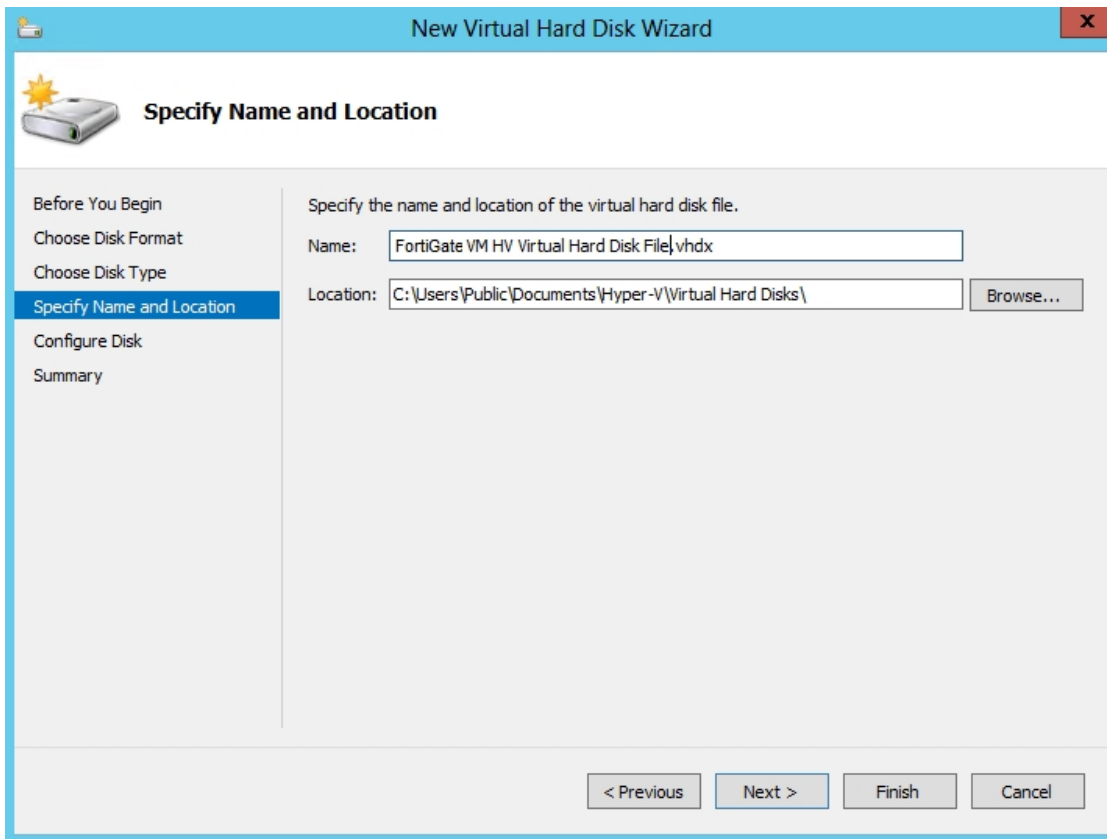

4. Select to use VHDX format virtual hard disks. This format supports virtual disks up to 64TB and is resilient to consistency issues that might occur from power failures. This format is not supported in operating systems earlier than Windows Server 2012. Note that FortiGate-VM does not support hard disks larger than 2TB.

Select **Next** to continue. The **Choose Disk Type** page opens.

5. Select the type of virtual disk you want to use. Select one of the following disk types:
- **Fixed size:** This type of disk provides better performance and is recommended for servers running applications with high levels of disk activity. The virtual hard disk file that is created initially uses the size of the virtual hard disk and does not change when data is deleted or added.
 - **Dynamic expanding:** This type of disk provides better use of physical storage space and is recommended for servers running applications that are not disk intensive. The virtual disk file that is created is small initially and changes as data is added.
 - **Differencing:** This type of disk is associated in a parent-child relationship with another disk that you want to leave intact. You can make changes to the data or operating system without affecting the parent disk, so that you can revert the changes easily. All children must have the same virtual hard disk format as the parent (VHD or VHDX).

Select **Next** to continue. The **Specify Name and Location** page opens.

6. Specify the name and location of the virtual hard disk file. Use the **Browse** button to select a specific file folder on your server.

Select **Next** to continue. The **Configure Disk** page opens.

The screenshot shows the 'New Virtual Hard Disk Wizard' window with the 'Configure Disk' step selected. The left sidebar contains the following steps: 'Before You Begin', 'Choose Disk Format', 'Choose Disk Type', 'Specify Name and Location', 'Configure Disk' (highlighted), and 'Summary'. The main area has a title 'Configure Disk' with a disk icon. Below the title, it says 'You can create a blank virtual hard disk or copy the contents of an existing physical disk.' There are two radio buttons: 'Create a new blank virtual hard disk' (selected) and 'Copy the contents of the specified physical disk:'. The 'Create a new blank virtual hard disk' option has a 'Size:' field with '30' entered and '(Maximum: 64 TB)' in parentheses. The 'Copy the contents of the specified physical disk:' option has a table listing physical hard disks. The table has two columns: 'Physical Hard Disk' and 'Size'. The rows are: '\\.\\PHYSICALDRIVE0' (1863 GB), '\\.\\PHYSICALDRIVE1' (125 MB), '\\.\\PHYSICALDRIVE2' (125 MB), '\\.\\PHYSICALDRIVE3' (125 MB), and '\\.\\PHYSICALDRIVE4' (125 MB). Below the table, there is a radio button for 'Copy the contents of the specified virtual hard disk' and a 'Path:' field with a 'Browse...' button. At the bottom, there are four buttons: '< Previous', 'Next >', 'Finish', and 'Cancel'.

Configure Disk

Before You Begin
Choose Disk Format
Choose Disk Type
Specify Name and Location
Configure Disk
Summary

You can create a blank virtual hard disk or copy the contents of an existing physical disk.

☒ Create a new blank virtual hard disk
Size: GB (Maximum: 64 TB)

☐ Copy the contents of the specified physical disk:

Physical Hard Disk	Size
\\.\PHYSICALDRIVE0	1863 GB
\\.\PHYSICALDRIVE1	125 MB
\\.\PHYSICALDRIVE2	125 MB
\\.\PHYSICALDRIVE3	125 MB
\\.\PHYSICALDRIVE4	125 MB

☐ Copy the contents of the specified virtual hard disk
Path:

< Previous Next > Finish Cancel

7. Select to **Create a new blank virtual hard disk** and enter the size of the disk in GB. The maximum size is dependent on your server environment.

Select **Next** to continue. The **Summary** page opens.

8. The summary page provides details of the virtual hard disk. Select **Finish** to create the virtual hard disk.
9. Select **Apply** to save the settings and select **OK** to exit the settings page.

High availability Hyper-V configuration

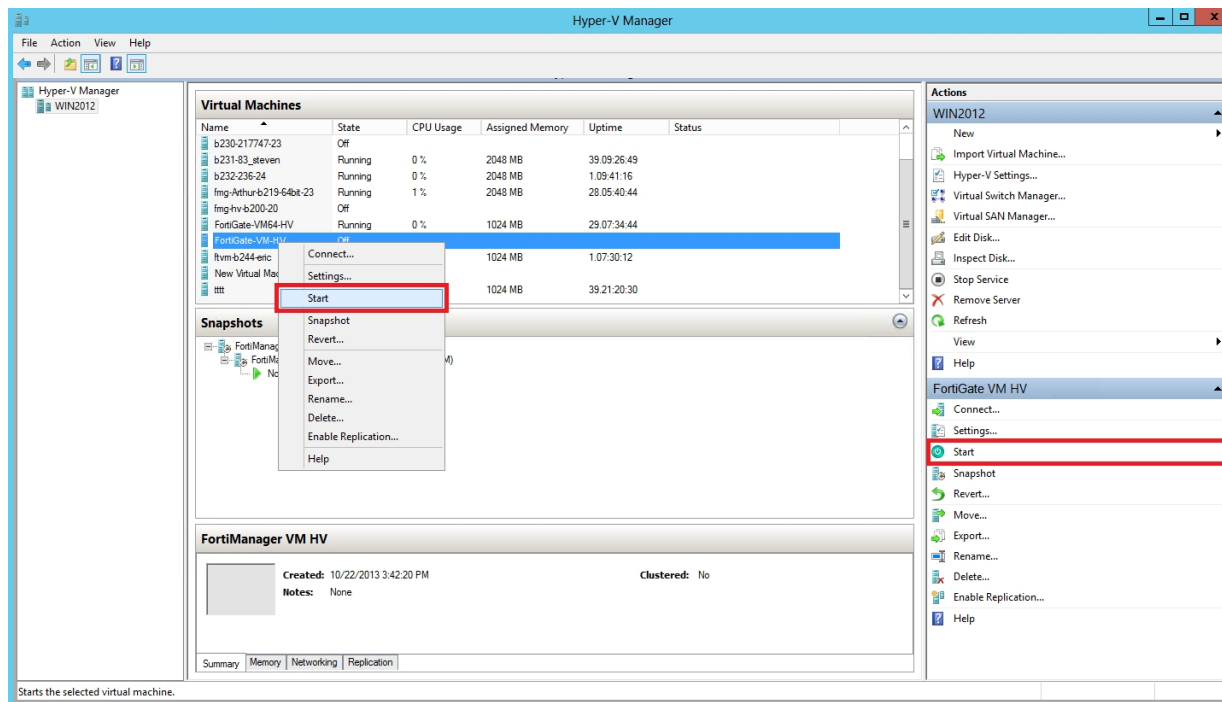

Promiscuous mode and support for MAC address spoofing is required for FortiGate-VM for Hyper-V to support FortiGate Clustering Protocol (FGCP) high availability (HA). By default the FortiGate-VM for Hyper-V has promiscuous mode enabled in the XML configuration file in the FortiGate-VM Hyper-V image. If you have problems with HA mode, confirm that this is still enabled.

In addition, because the FGCP applies virtual MAC addresses to FortiGate data interfaces and because these virtual MAC addresses mean that matching interfaces of different FortiGate-VM instances will have the same virtual MAC addresses you have to configure Hyper-V to allow MAC spoofing. But you should only enable MAC spoofing for FortiGate-VM data interfaces. You should not enable MAC spoofing for FortiGate HA heartbeat interfaces.

With promiscuous mode enabled and the correct MAC spoofing settings you should be able to configure HA between two or more FortiGate-VM for Hyper-V instances.

Start the FortiGate VM

You can now proceed to power on your FortiGate VM. Select the name of the FortiGate VM in the list of virtual machines, right-click, and select **Start** in the menu. Optionally, you can select the name of the FortiGate VM in the list of virtual machines and select **Start** in the **Actions** menu.

Deployment example – KVM

Once you have downloaded the FORTINET.out.kvm.zip file and extracted virtual hard drive image file fortios.qcow2, you can create the virtual machine in your KVM environment.

The following topics are included in this section:

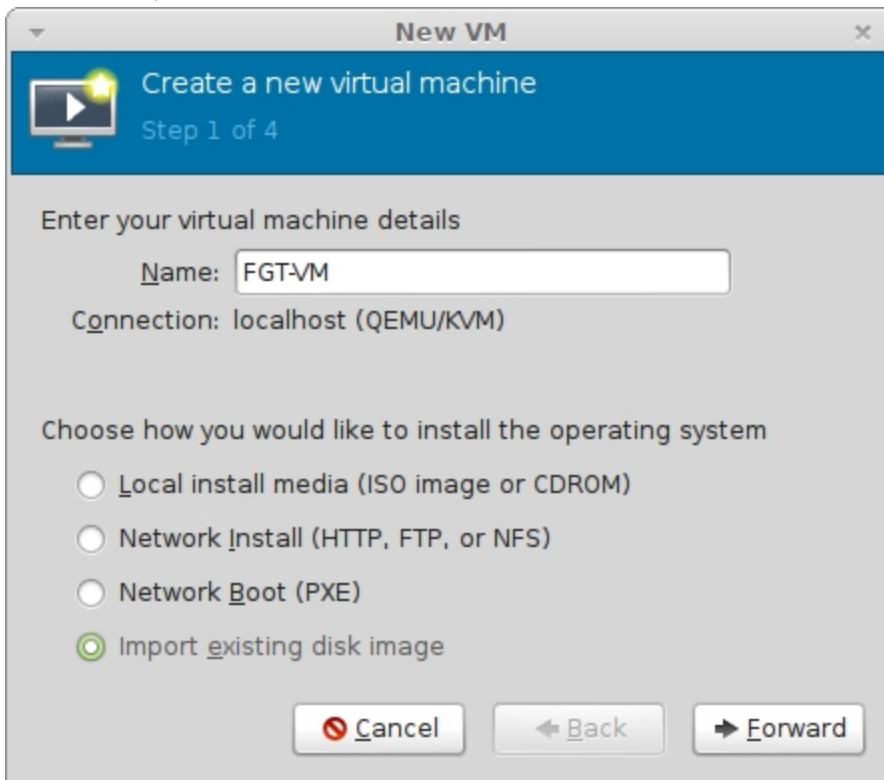

Create the FortiGate VM virtual machine

To create the FortiGate VM virtual machine:

1. Launch Virtual Machine Manager (virt-manager) on your KVM host server.

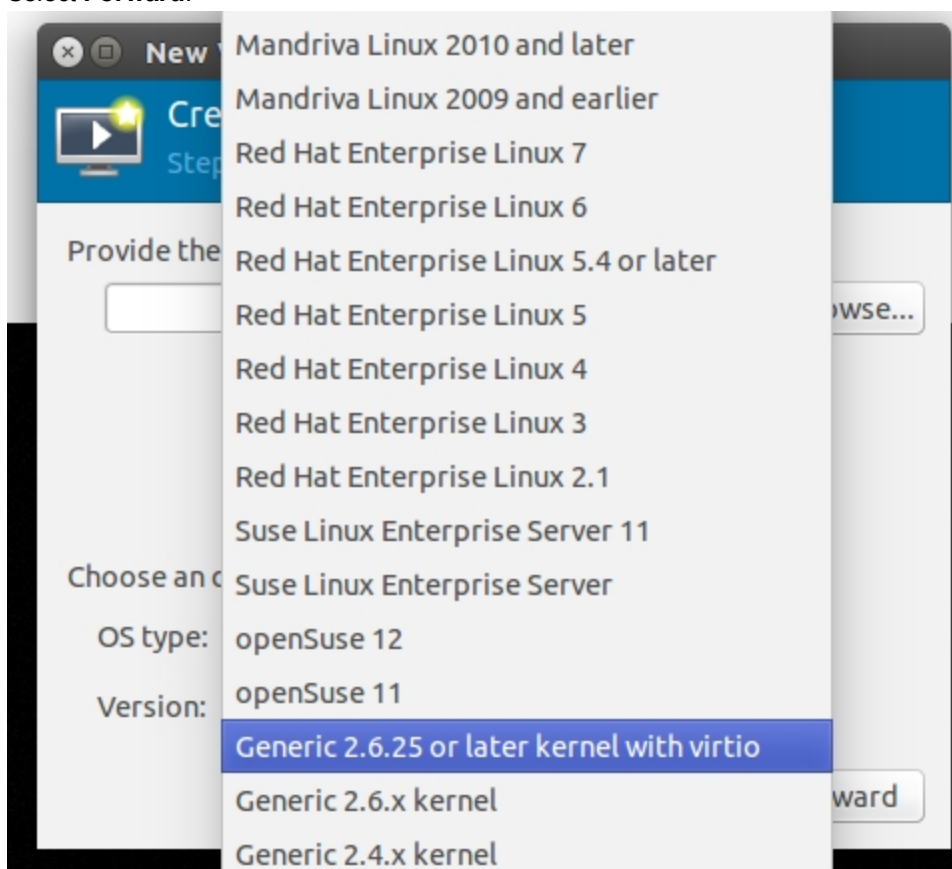

The **Virtual Machine Manager** home page opens.

2. In the toolbar, select **Create a new virtual machine**.

3. Enter a **Name** for the VM, FGT-VM for example.
4. Ensure that **Connection** is localhost. (This is the default.)
5. Select **Import existing disk image**.

6. Select **Forward**.

7. In **OS Type** select **Linux**.

8. In **Version**, select a Generic version with virtio.

9. Select **Browse**.

10. If you copied the fortios.qcow2 file to `/var/lib/libvirt/images`, it will be visible on the right. If you saved it somewhere else on your server, select **Browse Local** and find it.
11. Choose **Choose Volume**.
12. Select **Forward**.
13. Specify the amount of memory and number of CPUs to allocate to this virtual machine. The amounts must not exceed your license limits. See [Virtual FortiOS overview on page 3021](#).
14. Select **Forward**.
15. Expand **Advanced options**. A new virtual machine includes one network adapter by default. Select a network adapter on the host computer. Optionally, set a specific MAC address for the virtual network interface. Set **Virt Type** to **virtio** and **Architecture** to **qcow2**.
16. Select **Finish**.

Configure FortiGate VM hardware settings

Before powering on your FortiGate VM you must add the log disk and configure the virtual hardware of your FortiGate VM.

To configure settings for FortiGate VM on the server:

1. In the Virtual Machine Manager, locate the name of the virtual machine and then select **Open** from the toolbar.
2. Select **Add Hardware**. In the **Add Hardware** window select **Storage**.
3. Select **Create a disk image on the computer's hard drive** and set the size to 30GB.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

4. Enter:

Device type	Virtio disk
Cache mode	Default
Storage format	raw

Even though raw is the storage format listed, the qcow2 format is also supported.

5. Select **Network** to configure add more the network interfaces. The **Device type** must be **Virtio**.

A new virtual machine includes one network adapter by default. You can add more through the Add Hardware window. FortiGate VM requires four network adapters. You can configure network adapters to connect to a virtual switch or to network adapters on the host computer.

6. Select **Finish**.

Start the FortiGate VM

You can now proceed to power on your FortiGate VM. Select the name of the FortiGate VM in the list of virtual machines. In the toolbar, select **Console** and then select **Start**.

Deployment example – Open Xen

Once you have downloaded the FORTINET.out.Open Xen.zip file and extracted virtual hard drive image file fortios.qcow2, you can create the virtual machine in your OpenXen environment.

The following topics are included in this section:

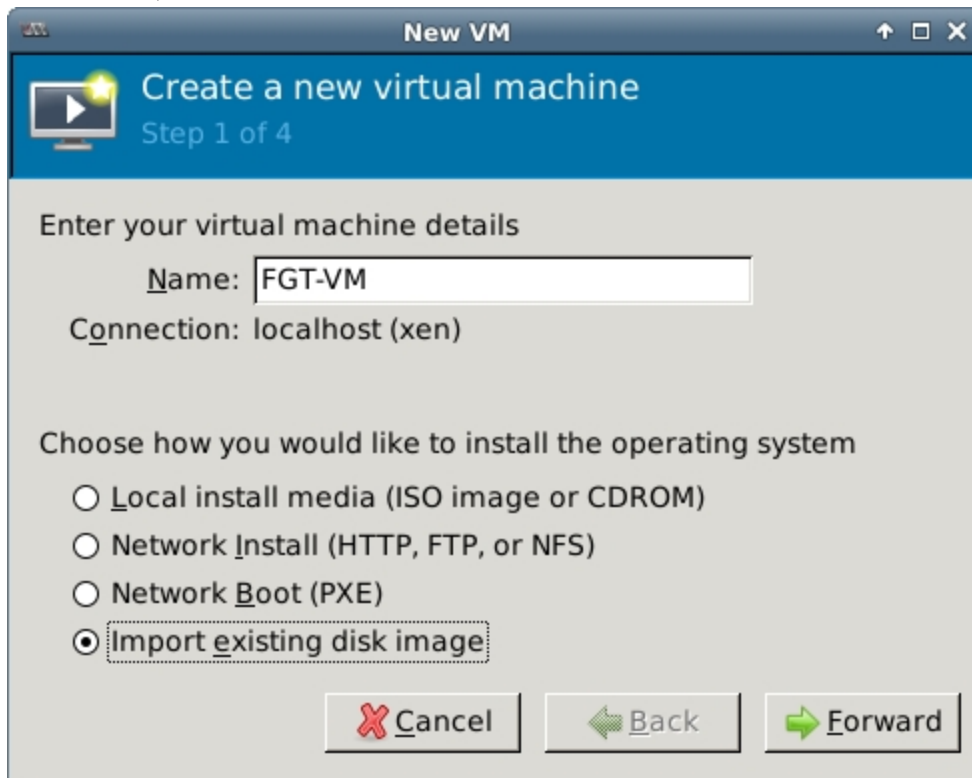

Create the FortiGate VM virtual machine

To create the FortiGate VM virtual machine:

1. Launch Virtual Machine Manager (virt-manager) on your Open Xen host server.

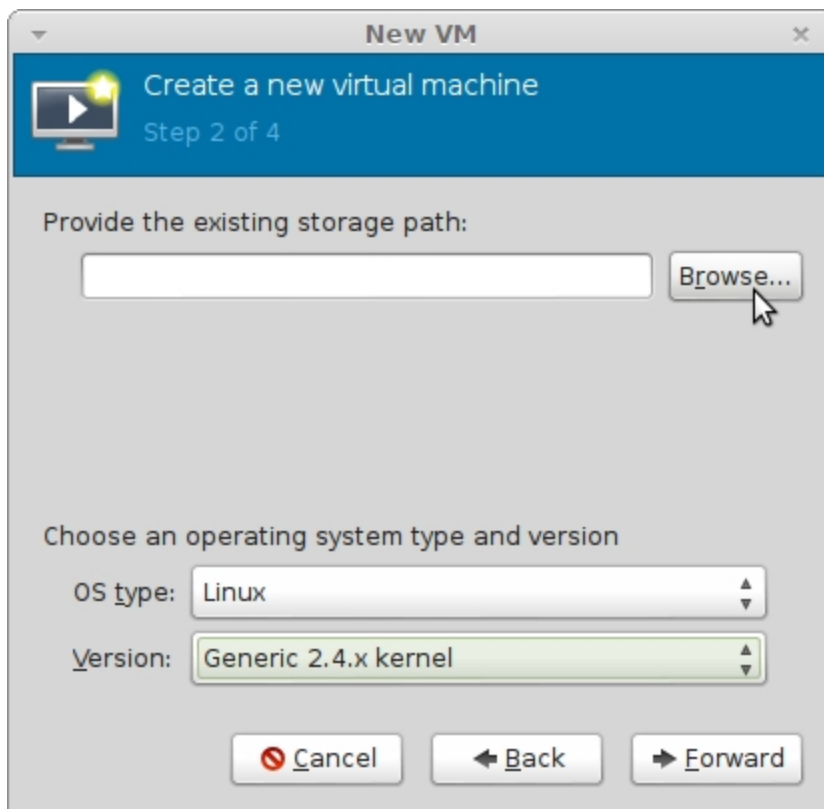

The **Virtual Machine Manager** home page opens.

2. In the toolbar, select **Create a new virtual machine**.

3. Enter a **Name** for the VM, FGT-VM for example.
4. Ensure that **Connection** is localhost. (This is the default.)
5. Select **Import existing disk image**.

6. Select **Forward**.

7. In **OS Type** select **Linux**.

8. In **Version**, select **Generic 2.4.x.kernel**.

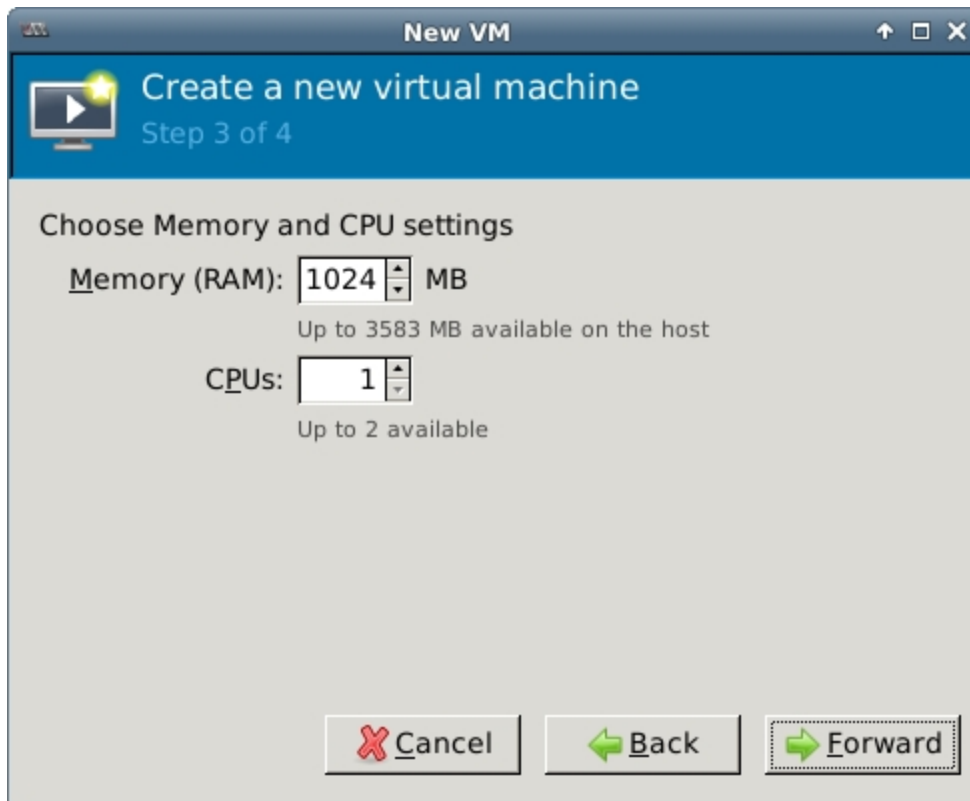

9. Select **Browse**.

The **Locate or create storage volume** window opens.

10. Select **Browse Local**, find the fortios.qcow2 disk image file.

11. Select fortios.qcow2 and select **Choose Volume**.

12. Select **Forward**.

New VM

Create a new virtual machine
Step 3 of 4

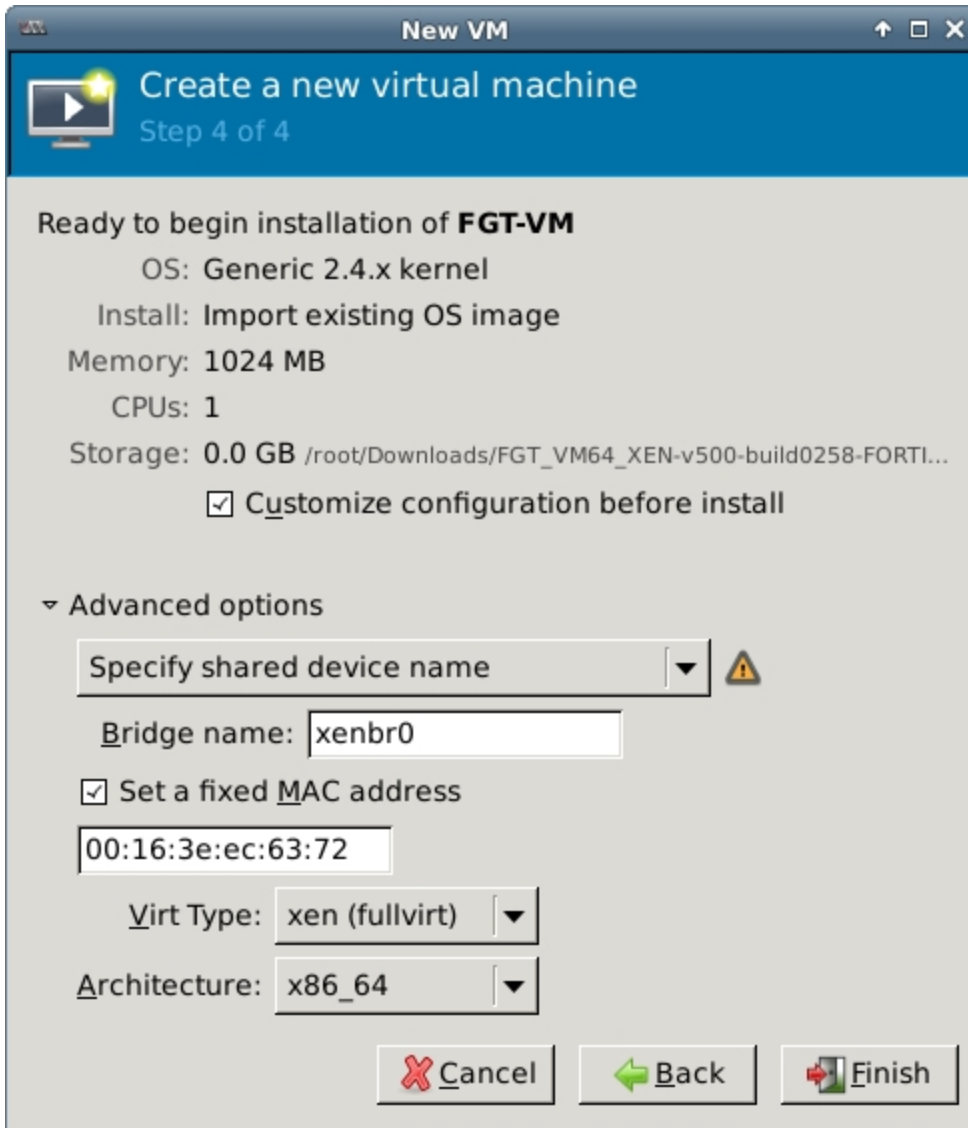

Choose Memory and CPU settings

Memory (RAM): 1024 MB
Up to 3583 MB available on the host

CPUs: 1
Up to 2 available

Cancel Back Forward

13. Specify the amount of memory and number of CPUs to allocate to this virtual machine. The amounts must not exceed your license limits.

14. Select Forward.

New VM

Create a new virtual machine
Step 4 of 4

Ready to begin installation of **FGT-VM**

OS: Generic 2.4.x kernel

Install: Import existing OS image

Memory: 1024 MB

CPUs: 1

Storage: 0.0 GB /root/Downloads/FGT_VM64_XEN-v500-build0258-FORTI...

☒ **Customize configuration before install**

▼ **Advanced options**

Specify shared device name ▼ ⚠

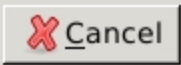

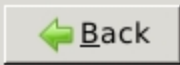

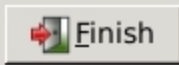

Bridge name: xenbr0

☒ Set a fixed MAC address

00:16:3e:ec:63:72

Virt Type: xen (fullvirt) ▼

Architecture: x86_64 ▼

- 15. Select **Customize configuration before install**.** This enables you to make some hardware configuration changes before VM creation is started.
- 16. Expand **Advanced options**.** A new virtual machine includes one network adapter by default. Select **Specify shared device name** and enter the name of the bridge interface on the Open Xen host. Optionally, set a specific MAC address for the virtual network interface. **Virt Type** and **Architecture** are set by default and should be correct.
- 17. Select **Finish**.**

The virtual machine hardware configuration window opens.

You can use this window to add hardware such as network interfaces and disk drives.

18. Select **Add Hardware**. In the **Add Hardware** window select **Storage**.
19. Select **Create a disk image on the computer's hard drive** and set the size to 30GB.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

20. Enter:

Device type	Virtio disk
Cache mode	Default
Storage format	raw

21. Select **Network** to configure add more the network interfaces. The **Device type** must be **Virtio**.

A new virtual machine includes one network adapter by default. You can add more through the Add Hardware window. FortiGate VM requires four network adapters. You can configure network adapters to connect to a virtual

switch or to network adapters on the host computer.

22. Select **Finish.**

23. Select **Begin Installation.** After the installation completes successfully, the VM starts and the console window opens.

Deployment example – Citrix XenServer

Once you have downloaded the FORTINET.out.CitrixXen.zip file and extracted the files, you can create the virtual machine in your Citrix Xen environment.

The following topics are included in this section:

Create the FortiGate VM virtual machine (XenCenter)

To create the FortiGate VM virtual machine from the OVF file

1. Launch XenCenter on your management computer.

The management computer can be any computer that can run Citrix XenCenter, a Windows application.

2. If you have not already done so, select **ADD a server**. Enter your Citrix XenServer IP address and the root logon credentials required to manage that server.

Your Citrix XenServer is added to the list in the left pane.

The **Virtual Machine Manager** home page opens.

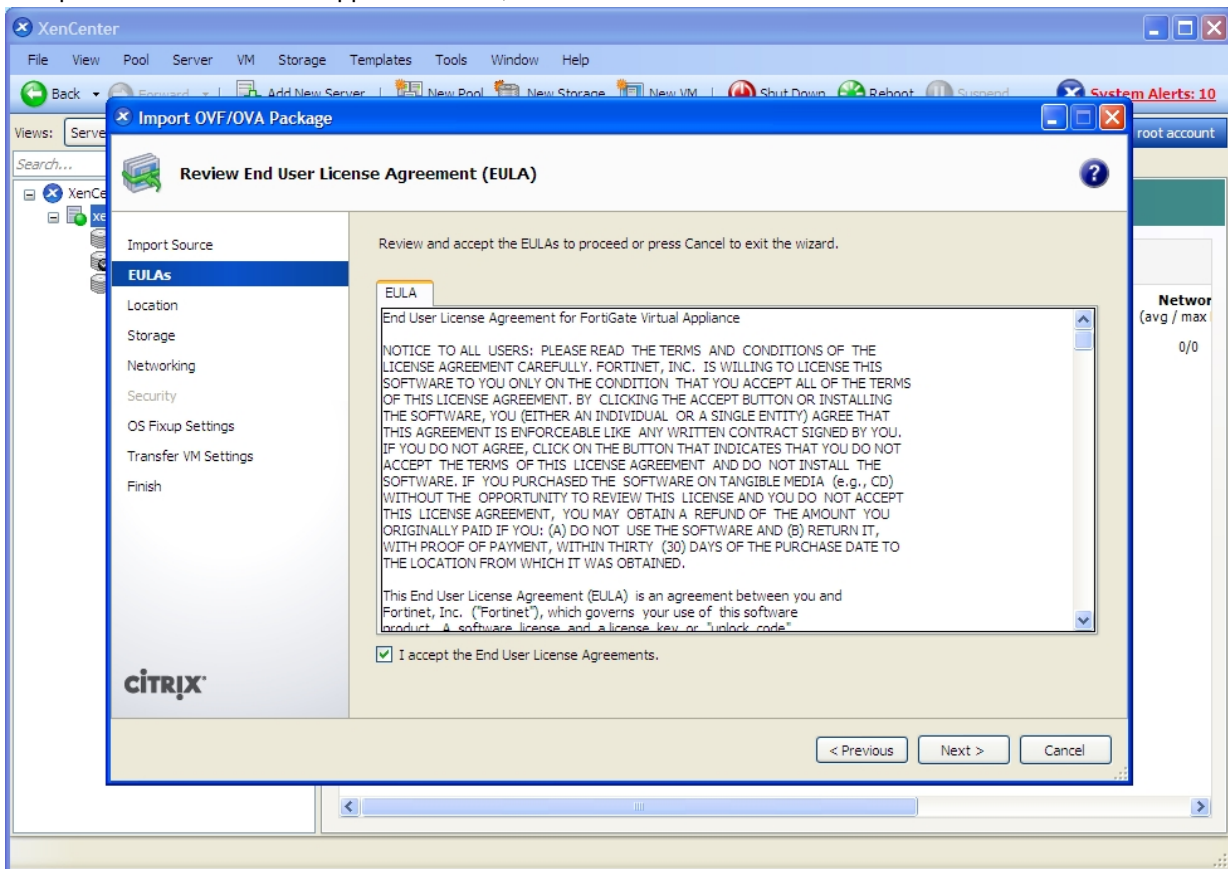

3. Go to **File > Import**. An import dialog will appear.

- Click the **Browse** button, find the FortiGate-VM64-Xen.ovf template file, then click **Open**.

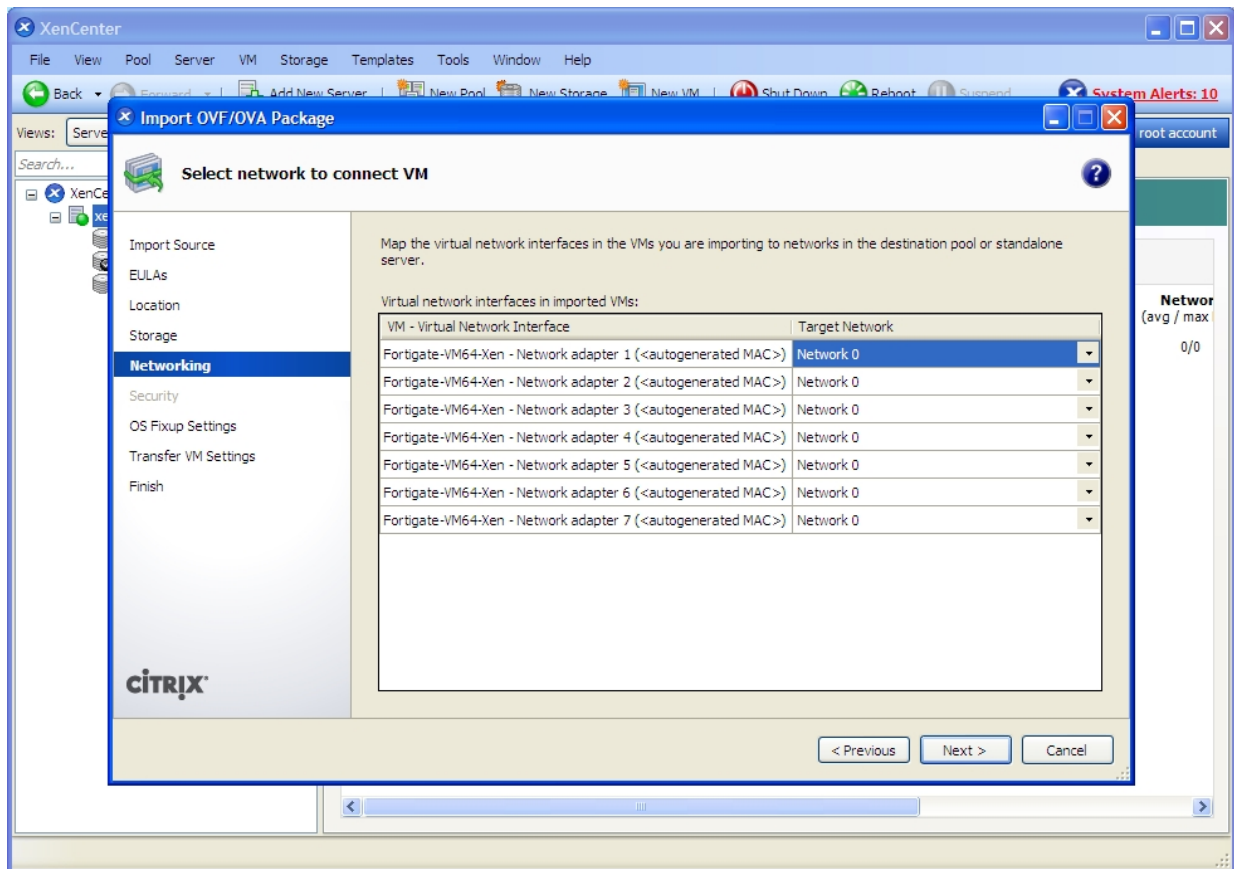

- Select **Next**.

6. Accept the FortiGate Virtual Appliance EULA, then select **Next**.

7. Choose the pool or standalone server that will host the VM, then select **Next**.
8. Select the storage location for FortiGate VM disk drives or accept the default. Select **Next**.

9. Configure how each vNIC (virtual network adapter) in FortiGate VM will be mapped to each vNetwork on the Citrix XenServer, then click **Next**.

10. Click **Next** to skip OS fixup.
11. Select **Next** to use the default network settings for transferring the VM to the host.
12. Select **Finish**.

The Citrix XenServer imports the FortiGate VM files and configures the VM as specified in the OVF template. Depending on your computer's hardware speed and resource load, and also on the file size and speed of the network connection, this might take several minutes to complete.

When VM import is complete, the XenCenter left pane includes the FortiGate VM in the list of deployed VMs for your Citrix XenServer.

Configure virtual hardware

Before you start your FortiGate-VM for the first time, you need to adjust your virtual machine's virtual hardware settings to meet your network requirements.

Configuring number of CPUs and memory size

Your FortiGate-VM license limits the number CPUs and amount of memory that you can use. The amounts you allocate must not exceed your license limits.

To access virtual machine settings

1. Open XenCenter.
2. Select your FortiGate VM in the left pane.
The tabs in the right pane provide access to the virtual hardware configuration. The Console tab provides access to the FortiGate console.
1. To set the number of CPUs
2. In the XenCenter left pane, right-click the FortiGate VM and select Properties.
The Properties window opens.
3. In the left pane, select CPU.

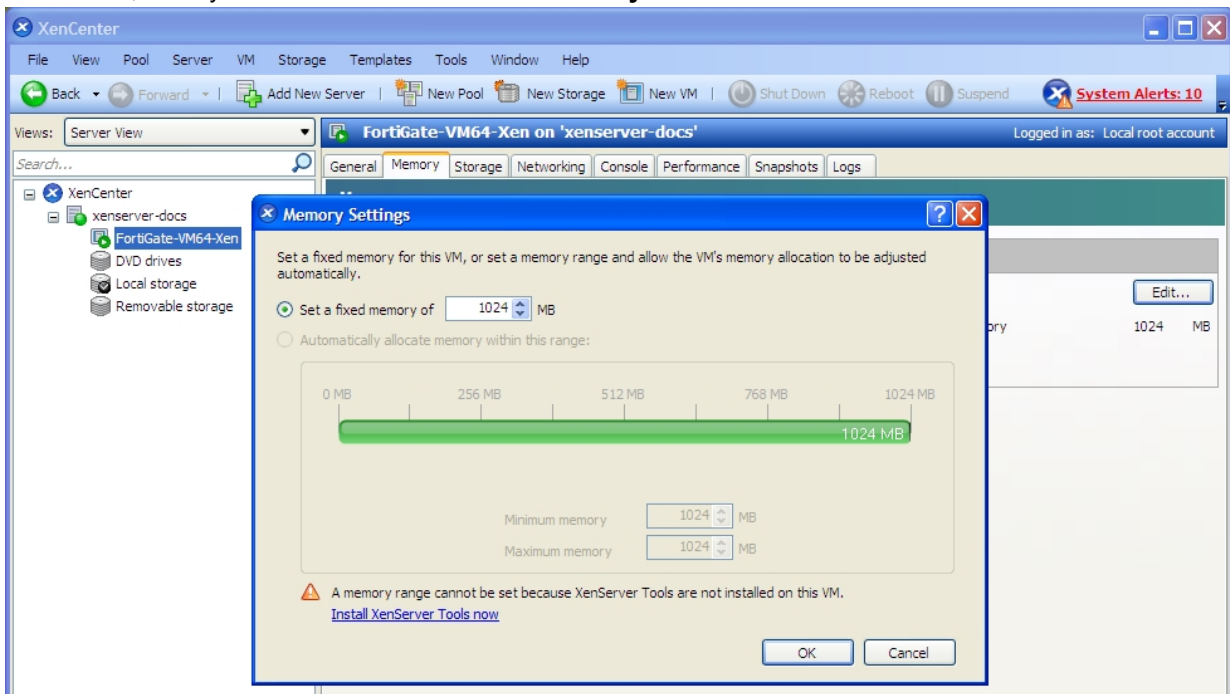

4. Adjust **Number of CPUs** and then select **OK**.

XenCenter will warn if you select more CPUs than the Xen host computer contains. Such a configuration might reduce performance.

To set memory size

1. In the XenCenter left pane, select the FortiGate VM.
2. In the right pane, select the **Memory** tab.

3. Select **Edit**, modify the value in the **Set a fixed memory of** field and select **OK**.

Configuring disk storage

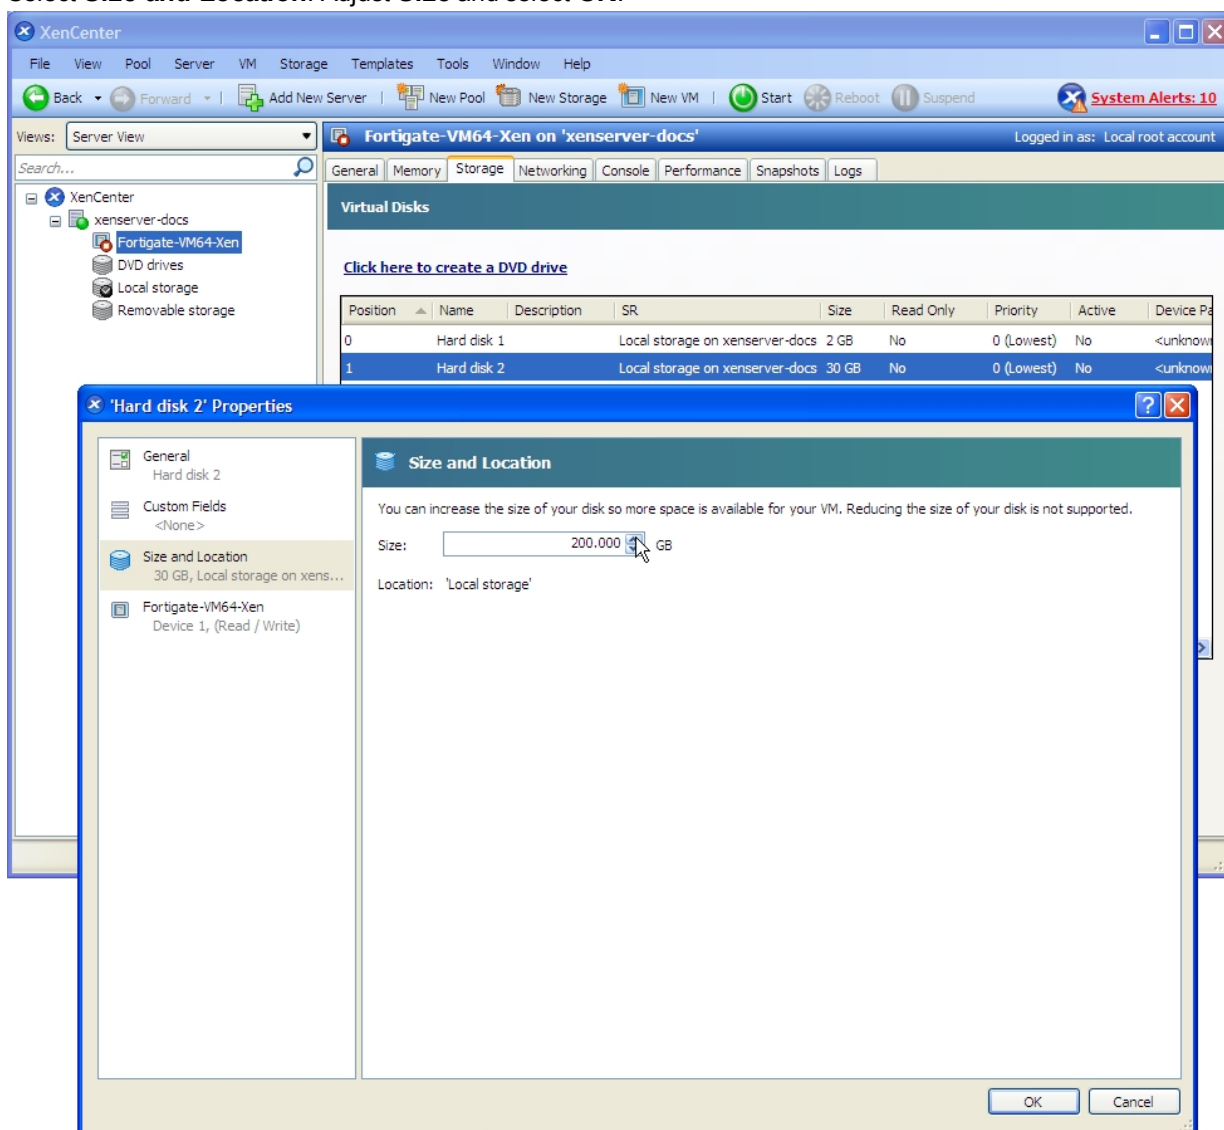

By default the FortiGate VM data disk 30GB. You will probably want to increase this. Disk resizing must be done before you start the VM for the first time.

To resize the FortiGate data disk

1. In the XenCenter left pane, select the FortiGate VM.
2. Select the **Storage** tab. Select **Hard disk 2** (the 30GB drive), then select **Properties**.

The '**Hard disk 2** Properties' window opens.

3. Select **Size and Location**. Adjust **Size** and select **OK**.

FortiGate VM initial configuration

Before you can connect to the FortiGate VM web-based manager you must configure a network interface in the FortiGate VM console. Once an interface with administrative access is configured, you can connect to the FortiGate VM web-based Manager and upload the FortiGate VM license file that you downloaded from the [Customer Service & Support](#) website.

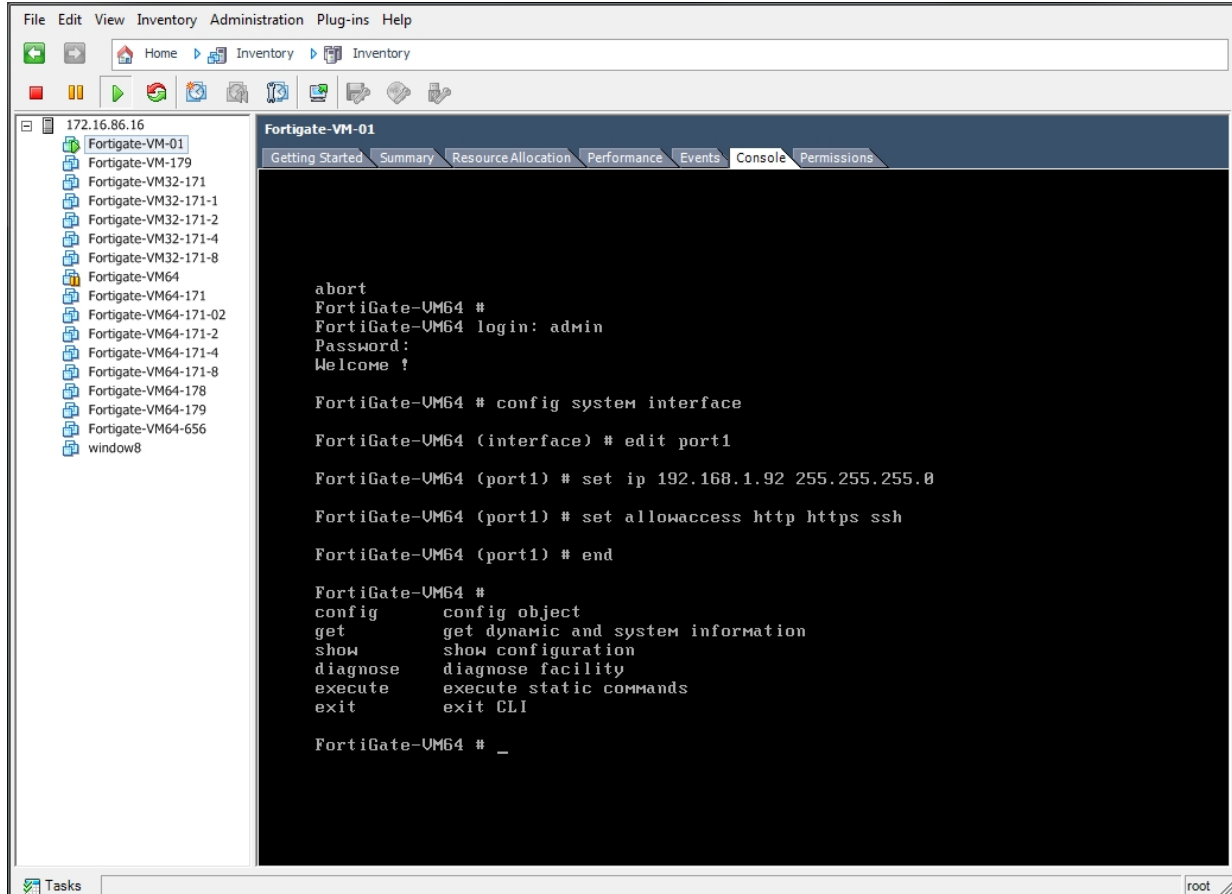

The following topics are included in this section:

Set FortiGate VM port1 IP address

Hypervisor management environments include a guest console window. On the FortiGate VM, this provides access to the FortiGate console, equivalent to the console port on a hardware FortiGate unit. Before you can access the Web-based manager, you must configure FortiGate VM port1 with an IP address and administrative access.

To configure the port1 IP address:

1. In your hypervisor manager, start the FortiGate VM and access the console window. You might need to press Return to see a login prompt.

Example of FortiGate VM console access:

2. At the FortiGate VM login prompt enter the username `admin`. By default there is no password. Just press Return.
3. Using CLI commands, configure the port1 IP address and netmask. Also, HTTP access must be enabled because until it is licensed the FortiGate VM supports only low-strength encryption. HTTPS access will not work.

For example:

```

config system interface
edit port1
set ip 192.168.0.100 255.255.255.0
append allowaccess http
end
  
```

You can also use the `append allowaccess` CLI command to enable other access protocols, such as `auto-ipsec`, `http`, `probe-response`, `radius-acct`, `snmp`, and `telnet`. The `ping`, `https`, `ssh`, and `fgfm` protocols are enabled on the `port1` interface by default.

4. To configure the default gateway, enter the following CLI commands:

```
config router static
edit 1
set device port1
set gateway <class_ip>
end
```

You must configure the default gateway with an IPv4 address. FortiGate VM needs to access the Internet to contact the FortiGuard Distribution Network (FDN) to validate its license.

5. To configure your DNS servers, enter the following CLI commands:

```
config system dns
set primary <Primary DNS server>
set secondary <Secondary DNS server>
end
```

The default DNS servers are 208.91.112.53 and 208.91.112.52.

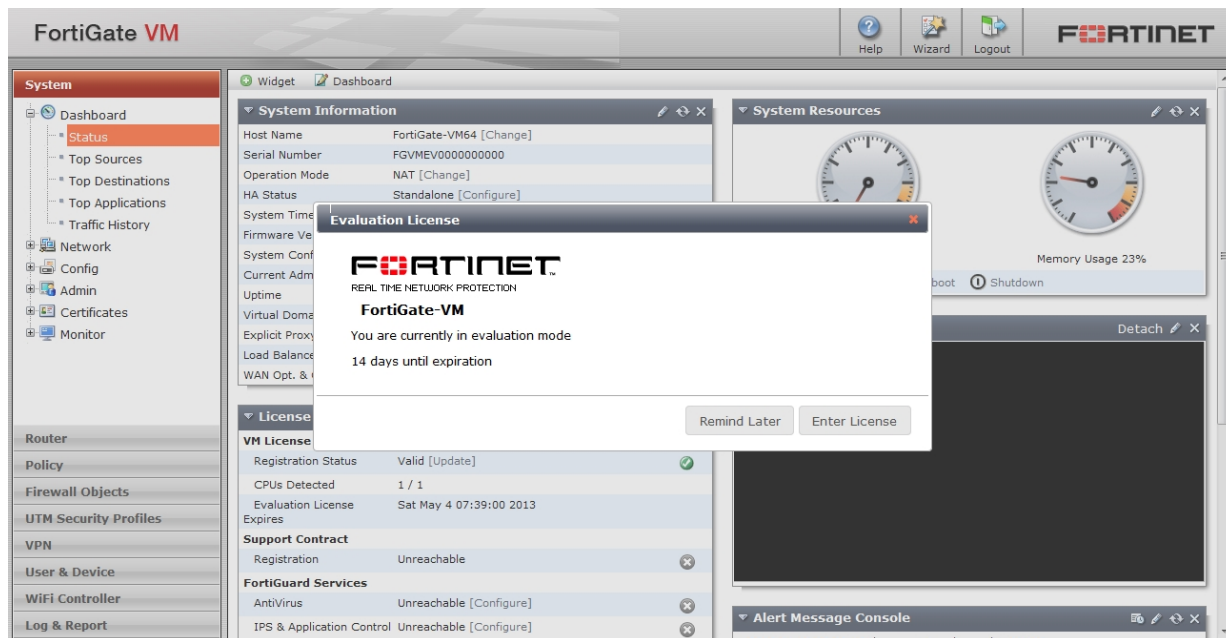

6. To upload the FortiGate VM license from an FTP or TFTP server, use the following CLI command:

```
execute restore vmlicense {ftp | tftp} <VM license file name> <Server IP or FQDN>
[:server port]
```

You can also upload the license in the FortiGate VM Web-based Manager. See [Set FortiGate VM port1 IP address on page 3082](#).

Web-based Manager and Evaluation License dialog box

Connect to the FortiGate VM web-based manager

When you have configured the port1 IP address and netmask, launch a web browser and enter the IP address that you configured for port1. At the login page, enter the username `admin` and password field and select **Login**. The default password is no password. The Web-based Manager will appear with an **Evaluation License** dialog box.

Due to low encryption on the FortiGate side of the connection, some modern browsers will not allow the connection. If that is the case, the adjusting of the browser settings is unlikely to make a difference. There are two options:

- Use FTP or TFTP to apply the license
- Make sure that the interface on the port being accessed has been configured to allow HTTP/HTTPS access

Upload the FortiGate VM license file

Every Fortinet VM includes a 15-day trial license. During this time the FortiGate VM operates in evaluation mode. Before using the FortiGate VM you must enter the license file that you downloaded from the [Customer Service & Support](#) website upon registration.

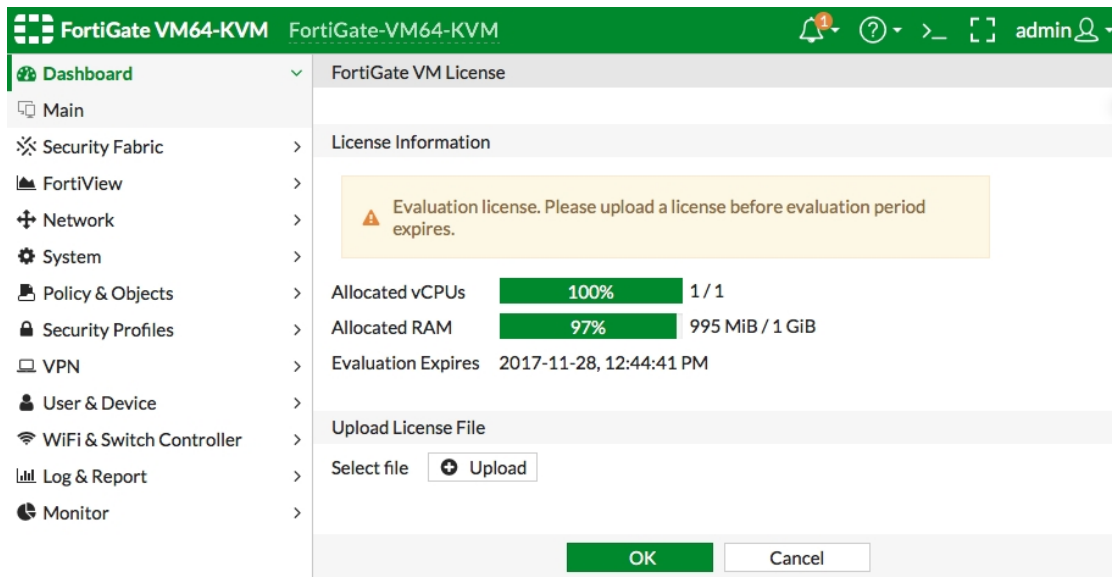

GUI

To upload the FortiGate VM license file:

1. There are 2 ways to get to the License upload window.

- i. In the **Dashboard > Main** window, in the **Virtual Machine** widget, left click on the **FGVMEV** (FortiGate-VM Evaluation) **License** icon. This will reveal a menu of selections to take you to directly to the **FortiGate VM License** window or to the **FortiGuard Details** window.
 - ii. Go to **System > FortiGuard**. In the **Larcentist Information** section, go to the **Virtual Machine** row and click on the link to **FortiGate VM License**.
2. In the **Evaluation License** dialog box, select **Enter License**.
The license upload page opens.

License upload page:

3. Select **Upload** and locate the license file (.lic) on your computer. Select **OK** to upload the license file.
4. Refresh the browser to login.
5. Enter `admin` in the Name field and select **Login**. The VM registration status appears as valid in the License Information widget once the license has been validated by the FortiGuard Distribution Network (FDN) or FortiManager for closed networks.

Modern browsers can have an issue with allowing connecting to a FortiGate if the encryption on the device is too low. Adjusting browser settings does not normally mitigate the issue. If this happens, Admins must use a FTP/TFTP server to apply the license.

CLI

You can also upload the license file via the CLI using the following CLI command:

```
execute restore vmlicense {ftp | tftp} <filename string> <ftp server>[:ftp port]
```

Example:

The following is an example output when using a tftp server to install license.

```
exec restore vmlicense tftp license.lic 10.0.1.2
This operation will overwrite the current VM license!Do you want to continue? (y/n)y
```

```
Please wait...Connect to tftp server 10.0.1.2 ...
Get VM license from tftp server OK.
VM license install succeeded.
Rebooting firewall.
```

The command has the side effect of rebooting the firewall without giving you a chance to back out or delay the reboot, so be careful about the timing of using the command.

Validate the FortiGate VM license with FortiManager

You can validate your FortiGate VM license with some models of FortiManager. To determine whether your FortiManager unit has the VM Activation feature, see Features section of the [FortiManager Product Data sheet](#).

To validate your FortiGate VM with your FortiManager:

1. To configure your FortiManager as a closed network, enter the following CLI command on your FortiManager:

```
config fmupdate publicnetwork
  set status disable
end
```
2. To configure FortiGate VM to use FortiManager as its override server, enter the following CLI commands on your FortiGate VM:

```
config system central-management
  set mode normal
  set type fortimanager
  set fmg <IPv4 address of the FortiManager device>
  set fmg-source-ip <Source IPv4 address when connecting to the FortiManager device>
  set include-default-servers disable
  set vdom <Enter the name of the VDOM to use when communicating with the FortiManager device>
end
```
3. Load the FortiGate VM license file in the Web-based Manager. Go to **System > Dashboard > Status**. In the **License Information** widget, in the **Registration Status** field, select **Update**. Browse for the `.lic` license file and select **OK**.
4. To activate the FortiGate VM license, enter the following CLI command on your FortiGate VM:

```
execute update-now
```
5. To check the FortiGate VM license status, enter the following CLI commands on your FortiGate VM:

```
get system status
```

The following output is displayed:

```
Version: Fortigate-VM v5.0,build0099,120910 (Interim)
Virus-DB: 15.00361(2011-08-24 17:17)
Extended DB: 15.00000(2011-08-24 17:09)
Extreme DB: 14.00000(2011-08-24 17:10)
IPS-DB: 3.00224(2011-10-28 16:39)
FortiClient application signature package: 1.456(2012-01-17 18:27)
Serial-Number: FGVM02Q105060000
License Status: Valid

dup:

```

Licensing timeout

In closed environments without Internet access, it is mandatory to perform offline licensing of the virtual FortiGate using a FortiManager as a license server. If the FortiGate-VM cannot perform license validation within the license timeout period, which is 30 days, the FortiGate will discard all packets and effectively ceasing operation as a firewall.

The status of the license will go through some status changes before it times out.

Status	Description
Valid	The FortiGate can connect and validate against a FortiManager or FDS
Warning	The FortiGate cannot connect and validate against a FortiManager or FDS. A check is made against how many days the Warning status has been continuous. If the number is less the 30 days the status does not change.
Invalid	The FortiGate cannot connect and validate against a FortiManager or FDS. A check is made against how many days the Warning status has been continuous. If the number is 30 days or more, the status changes to Invalid. The firewall ceases to function properly.

There is only a single log entry after the virtual FortiGate cannot access the license server for the license expiration period. This means that when you go searching the logs for a reason for the FortiGate being offline there will not be a long list of error logs that draw attention to the issue. There will only be the one entry.

Configure your FortiGate VM

Once the FortiGate VM license has been validated you can begin to configure your device. You can use the **Wizard** located in the top toolbar for basic configuration including enabling central management, setting the admin password, setting the time zone, and port configuration.

For more information on configuring your FortiGate VM see the FortiOS Handbook at <http://docs.fortinet.com>.

Chapter 30 - VoIP Solutions: SIP

This FortiOS Handbook chapter contains the following sections:

[Inside FortiOS: VoIP Protection](#) introduces FortiOS VoIP Protection

[Common SIP VoIP configurations](#) describes some common SIP configurations.

[SIP messages and media protocols](#) describes SIP messages and some common SIP media protocols.

[The SIP session helper](#) describes how the SIP session helper works and how to configure SIP support using the SIP session helper.

[The SIP ALG](#) describes how the SIP Application Layer Gateway (ALG) works and how to configure SIP support using the SIP ALG.

[Conflicts between the SIP ALG and the session helper](#) describes how to sort out conflicts between the SIP session helper and the ALG.

[Stateful SIP tracking, call termination, and session inactivity timeout](#) describes how the SIP ALG performs SIP stateful tracking, call termination and session activity timeouts.

[SIP and RTP/RTCP](#) describes how SIP relates to RTP and RTCP.

[How the SIP ALG creates RTP pinholes](#) describes how the SIP ALG creates pinholes.

[Configuration example: SIP in transparent mode](#) describes how to configure a FortiGate in transparent mode to support SIP.

[RTP enable/disable \(RTP bypass\)](#) describes RTP bypass.

[Opening and closing SIP register, contact, via and record-route pinholes](#) describes how FortiOS opens and closes these pinholes.

[Accepting SIP register responses](#) describes how to enable accepting SIP register responses.

[How the SIP ALG performs NAT](#) describes how the SIP ALG performs NAT.

[Enhancing SIP pinhole security](#) describes how to open smaller pinholes.

[Hosted NAT traversal](#) describes SIP hosted NAT traversal and how to configure it.

[SIP over IPv6](#) describes how to configure SIP over IPv6.

[Deep SIP message inspection](#) describes how deep SIP message inspection works.

[Blocking SIP request messages](#) describes how to block SIP request messages to prevent some common SIP attacks.

[SIP rate limiting](#) includes more options for preventing SIP attacks.

[SIP logging](#) describes how to enable SIP logging.

[Inspecting SIP over SSL/TLS \(secure SIP\)](#) describes how to inspect encrypted SIP traffic.

[SIP and HA-session failover and geographic redundancy](#) describes how to use FGCP HA to support SIP geographic redundancy.

[SIP and IPS](#) describes how to turn on IPS for SIP sessions.

[SIP debugging](#) describes some tools for debugging your SIP configuration.

What's new in FortiOS 6.0.1

VoIP features appear on the GUI when the FortiGate is operating in Flow mode, see [Enabling VoIP support from the GUI on page 3124](#).

What's new in FortiOS 6.0

By default, FortiOS 6.0 disables the SIP session helper, see [SIP session helper configuration overview on page 3116](#).

Inside FortiOS: Voice over IP (VoIP) protection

The FortiOS SIP Application Layer Gateway (ALG) allows SIP calls to pass through a FortiGate by opening SIP and RTP pinholes and performing source and destination IP address and port translation for SIP and RTP packets.

There are a large number of SIP-related Internet Engineering Task Force (IETF) documents (Request for Comments) that define behavior of SIP and related applications. FortiOS completely support [RFC 3261](#) for SIP, [RFC 4566](#) for SDP and [RFC 3262](#) for Provisional Response Acknowledgment (PRACK). FortiOS also supports other SIP and SIP-related RFCs and performs Deep SIP message inspection for SIP statements defined in other SIP RFCs.

Advanced voice over IP protection

The FortiOS SIP Application Level Gateway (ALG) protects Voice over IP (SIP and SDP) services in Unified Communication and NGN/IMS networks with the following advanced VoIP defense mechanisms.

Deep SIP message inspection (also called deep SIP header inspection)

Verifies SIP and SDP header syntax and protects SIP servers from potential SIP Fuzzing attacks. When a violation is detected, FortiOS can impose counter measures and can also send automatic SIP response messages to offload processing from the SIP server.

SIP message rate limiting

Allows rate limiting of SIP messages per SIP request method. This prevents a SIP server from overload or from DoS attacks using particular SIP methods. For example, FortiOS can protect SIP servers from a flood of SIP REGISTER or INVITE messages, which can be caused by a DoS attack or a flash crowd.

RTP and RTCP pinholing

RTP pinholing only forwards RTP/RTCP packets that conform to the particular session description of the associated SIP dialog. If a SIP dialog is finished, FortiOS automatically closes the pinhole. RTP/RTCP pinholing is supported by FortiASIC acceleration and achieves high packet throughput at low jitter and delay.

Stateful SIP dialog tracking

FortiOS tracks SIP message sequences and prevents unwanted SIP messages that are not related to a particular SIP dialog. For instance, FortiOS can detect malicious SIP BYE messages that do not conform with the associated context of the SIP dialog.

Inspecting SIP over SSL/TLS (secure SIP)

Some SIP phones and SIP servers use SSL or TLS to encrypt SIP signalling traffic. To allow SIP over SSL/TLS calls to pass through the FortiGate unit, the encrypted signalling traffic has to be unencrypted and inspected. FortiOS intercepts and unencrypts and inspects the SIP packets. Allowed packets are then re-encrypted and forwarded to their destination.

Inspecting SIP on multiple ports

FortiOS can detect and inspect SIP and SDP UDP and TCP sessions and SIP SSL sessions and you can configure the ports that the SIP ALG monitors for these sessions. In addition you can configure two different ports for SIP UDP sessions and two different ports for SIP TCP sessions. The port configuration can be changed without affecting other parts of the SIP configuration.

Carrier grade protection

To protect VoIP infrastructure in carrier networks, FortiOS complies with typical carrier requirements for availability and robustness.

High availability

FortiOS supports a hot failover configuration with an active and a standby FortiGate device. FortiOS dynamically updates the context on the standby unit with SIP and RTP related data. This enables the standby unit to takeover stable voice calls in case of a planned or unplanned outage or failover of the active unit.

Geographical redundancy of SIP servers

In FortiOS SIP server cluster configurations the active and standby units can be deployed in different geographical locations. This configuration prevents a total outage of a SIP server infrastructure if one location goes offline. FortiOS supports the detection of SIP server outages (loss of heartbeats) and a redirect of SIP messages to the redundant SIP server location.

Logging and Reporting

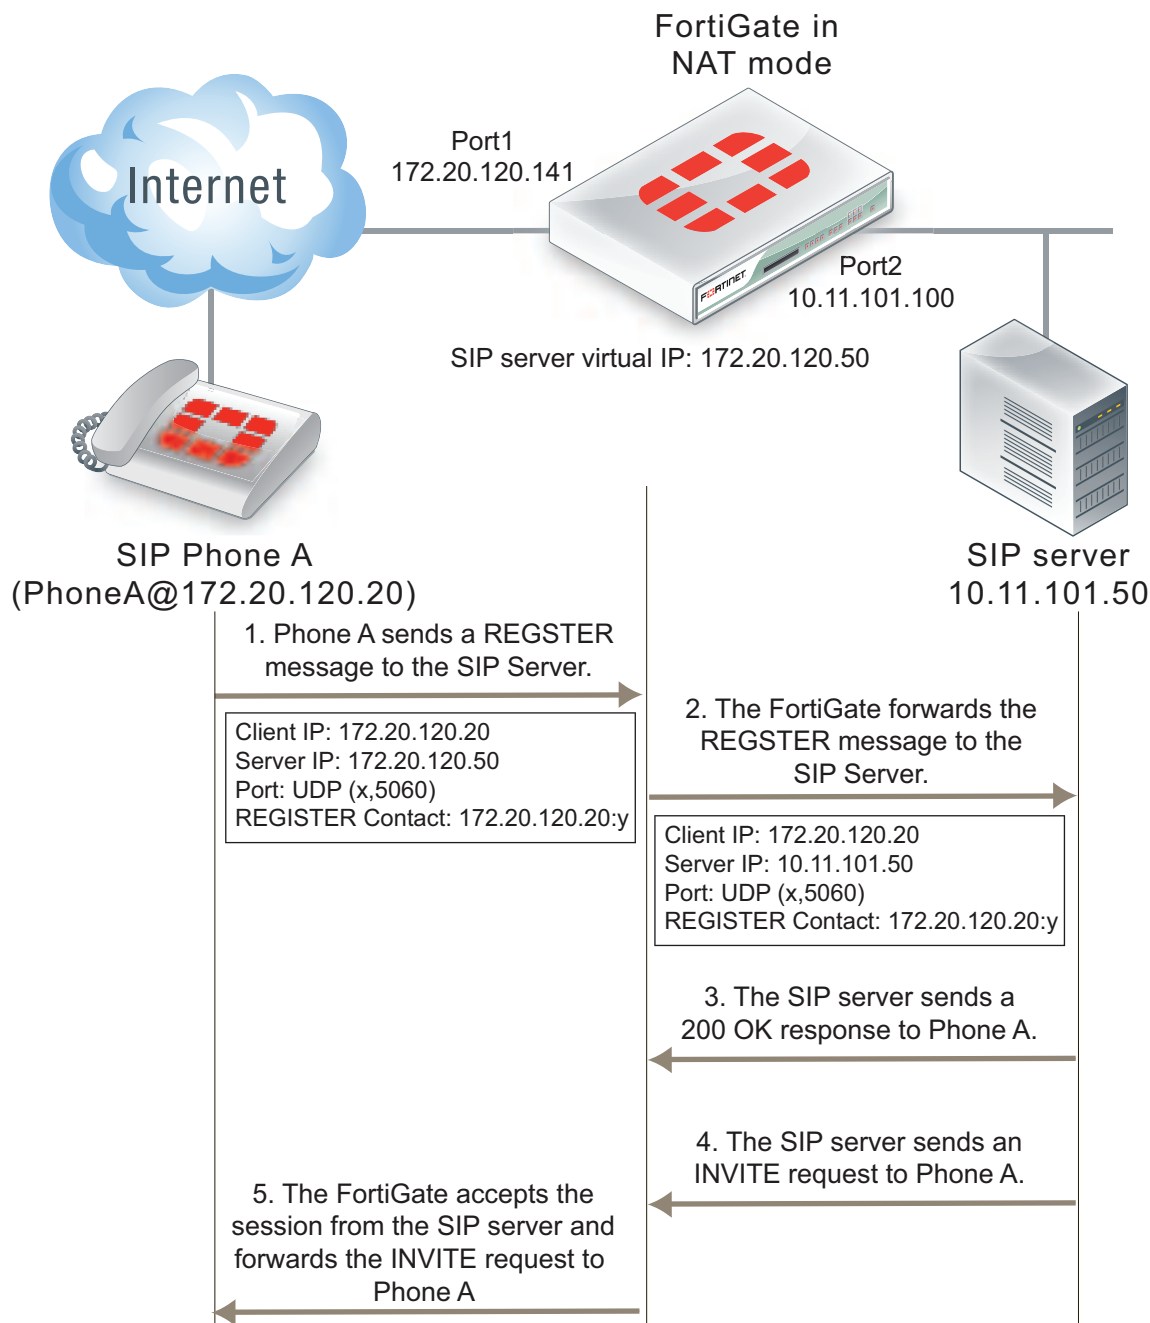

FortiOS can log call related information internally or to an external SYSLOG or FortiAnalyzer unit. This includes event logs that show particular SIP-related attacks or syntax violations with SIP messages or logs that summarize call statistics.

NAT/NAPT

FortiOS performs configurable network address translation for IP addresses in the SIP and SDP header. The SIP ALG follows the configured NAT addresses in firewall virtual IPs and changes SIP header IP addresses accordingly. RTP NAT is controlled by SIP/SDP and the firewall policy. This allows translating an unlimited number of IP addresses without adding specific RTP policies.

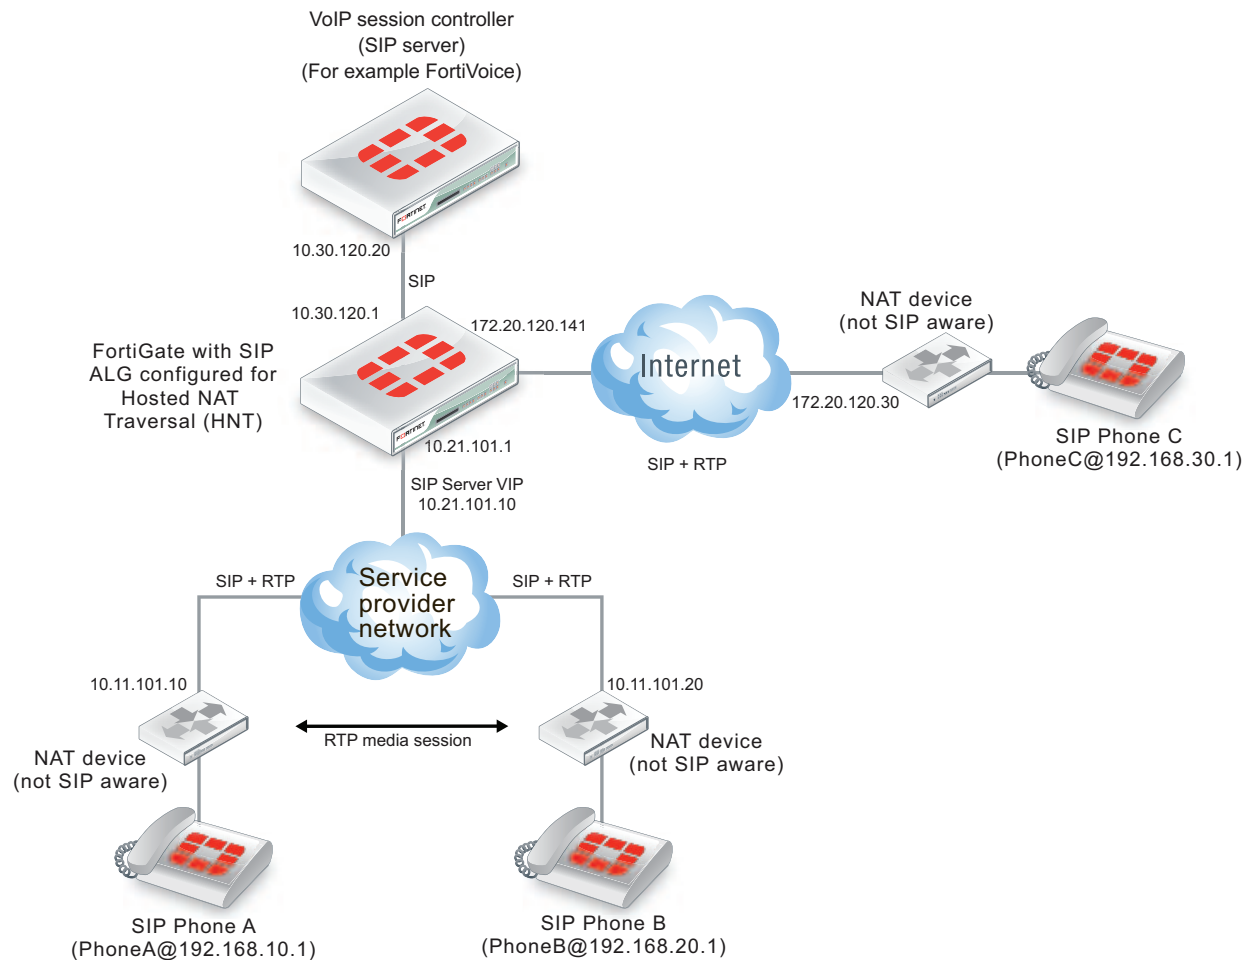

Header manipulation

FortiOS SIP and SDP header manipulation supports SIP Network Address Translation (NAT) through FortiGate units configured as NAT firewalls.

Hosted NAT traversal (HNT)

In many service provider networks, CPE firewall devices provide NAT without application awareness. This causes issues for SIP/SDP and RTP traffic, since UAC IP address information references to the internal network behind the far end firewall. VoIP calls cannot be connected successfully. FortiOS mitigates far end NAT issues (called Hosted NAT traversal) by probing the first RTP packet from the UAC and learning the far end NA(P)T binding. FortiOS then updates the internal NAT binding for RTP accordingly.

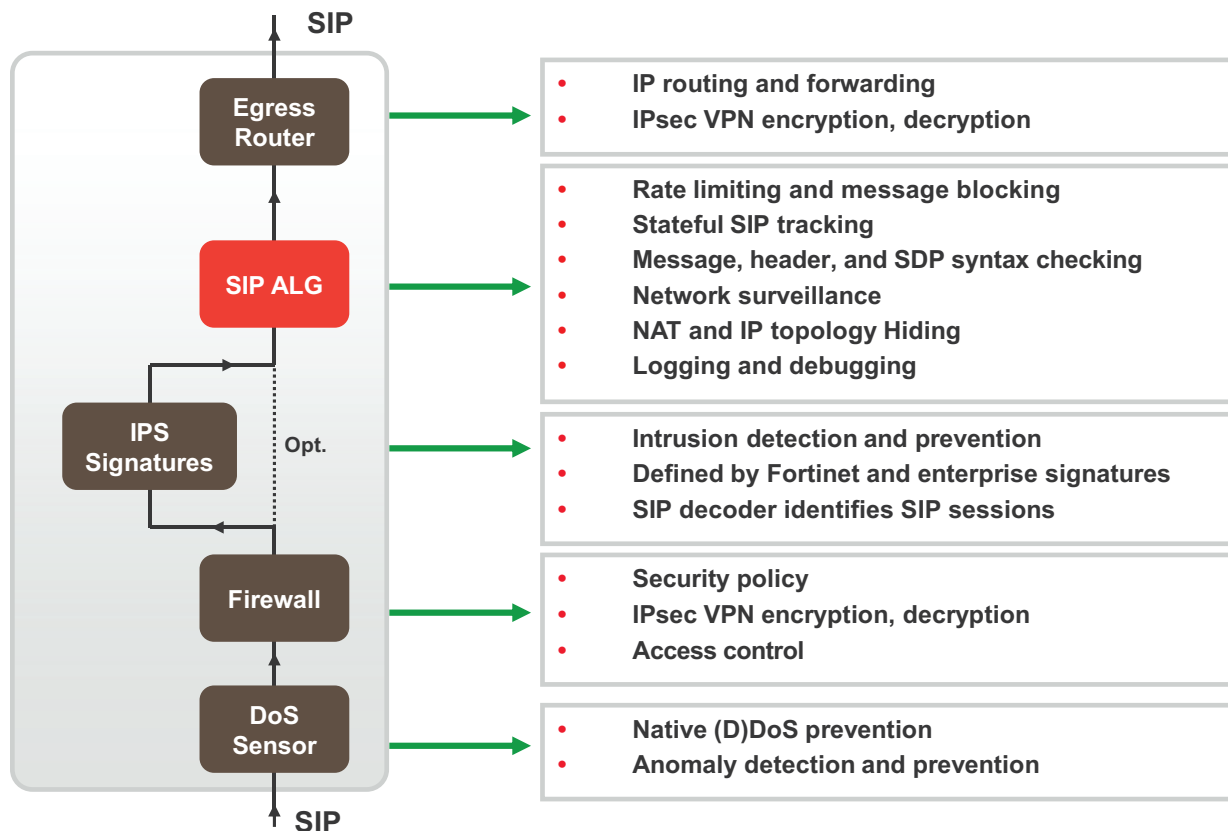

IP address conservation for NAT

In case of SIP and RTP NAT IP the original address information can get lost after translating to the provisioned IP addresses. This IP address information is sometimes required for detailed billing records or debugging purposes. FortiOS can maintain the original IP address information in a translated SIP header by adding it to the SIP/SDP info line (i=) or by adding it to the original attribute (o=). Either option can be selected depending on the SIP billing environment.

SIP ALG activation

The FortiOS SIP ALG is applied to SIP traffic accepted by a firewall policy that includes a VoIP profile. The VoIP profile controls how the SIP ALG processes SIP sessions. FortiOS also includes a high-performance SIP session helper that provides limited SIP functionality. In most cases the SIP ALG should be used because the SIP ALG supports the complete range of FortiOS SIP features.

SIP over IPv6

FortiOS, operating in NAT/Route and in transparent mode supports SIP over IPv6. The SIP ALG can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

Platform support and hardware acceleration

FortiOS supports VoIP protection with the SIP ALG on all FortiGate hardware platforms. Whenever a FortiGate unit provides FortiASIC or SPM HW acceleration, the SIP ALG will use this option to fast-path RTP/RTCP traffic.

As well, since the SIP ALG is proxy-based, SIP control packets are not offloaded to NP4 or NP6 processors. But actual voice or other media traffic can be offloaded to NP4 or NP6 processors after the SIP session is established. Many FortiGate units also support low latency hardware acceleration configurations that also enhance SIP voice transmission.

FortiGate hardware acceleration provides a high throughput solution at very low jitter and delay. FortiOS provides efficient and highly scalable protection for VoIP in emerging Enterprise and Carrier network. This complements Fortinet's NGFW and UTM offerings. VoIP protection can be easily added to any firewall policy just by adding a VoIP profile.

VoIP protection is supported in FortiAnalyzer and FortiManager. Centralized logging and management are essential for carrier and MSSP service provider and are influencing business case calculations.

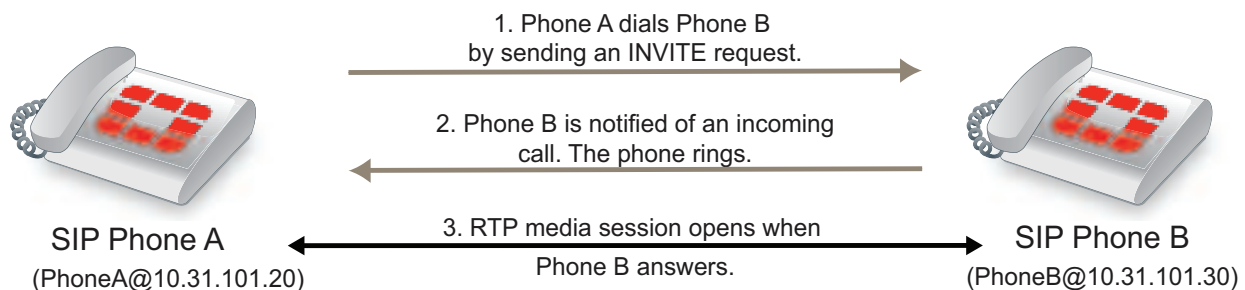

Common SIP VoIP configurations

This section describes some common SIP VoIP configurations and simplified SIP dialogs for these configurations. This section also shows some examples of how adding a FortiGate affects SIP processing.

Peer to peer configuration

In the peer to peer configuration shown below, two SIP phones (in the example, FortiFones) communicate directly with each other. The phones send SIP request and response messages back and forth between each other to establish the SIP session.

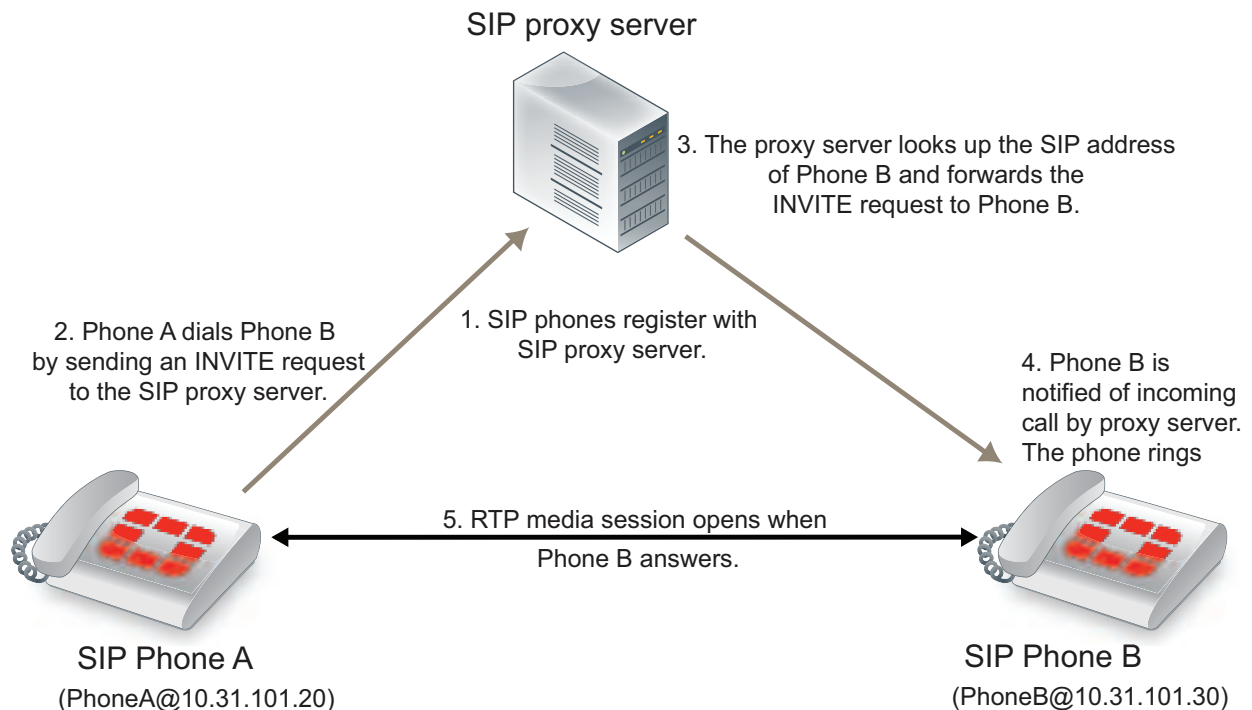

SIP peer to peer configuration

Peer to peer configurations are not very common because they require the SIP phones to keep track of the names and addresses of all of the other SIP phones that they can communicate with. In most cases a SIP proxy or re-direct server maintains addresses of a large number of SIP phones and a SIP phone starts a call by contacting the SIP proxy server.

SIP proxy server configuration

A SIP proxy server acts as an intermediary between SIP phones and between SIP phones (for example, two FortiFones) and other SIP servers. As shown below, SIP phones send request and response messages to the SIP proxy server. The proxy server forwards the messages to other clients or to other SIP proxy servers. Proxy servers can hide SIP phones by proxying the signaling messages. To the other users on the VoIP network, the signaling invitations look as if they come from the SIP proxy server.

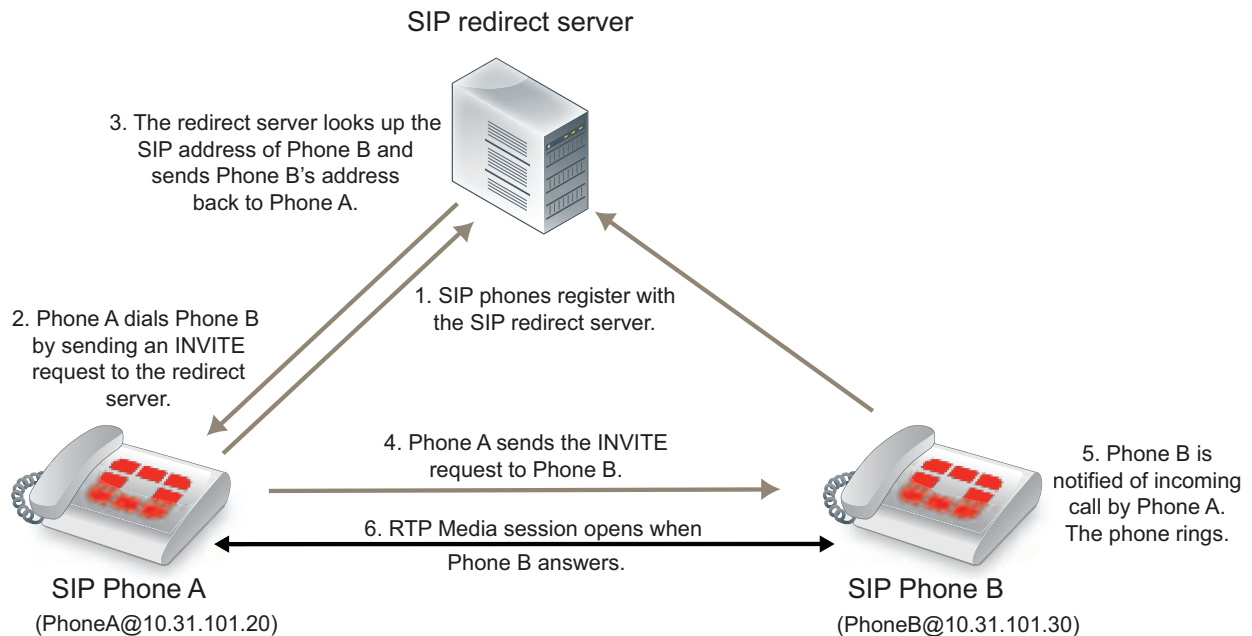

SIP in proxy mode

A common SIP configuration would include multiple networks of SIP phones. Each of the networks would have its own SIP server. Each SIP server would proxy the communication between phones on its own network and between phones in different networks.

SIP redirect server configuration

A SIP redirect server accepts SIP requests, maps the addresses in the request into zero or more new addresses and returns those addresses to the client. The redirect server does not initiate SIP requests or accept calls. As shown below, SIP clients send INVITE requests to the redirect server, which then looks up the destination address. The redirect server returns the destination address to the client. The client uses this address to send the INVITE request directly to the destination SIP client.

SIP in redirect model

SIP registrar configuration

A SIP registrar accepts SIP REGISTER requests from SIP phones for the purpose of updating a location database with this contact information. This database can then become a SIP location service that can be used by SIP proxy servers and redirect servers to locate SIP clients. As shown below, SIP clients send REGISTER requests to the SIP registrar.

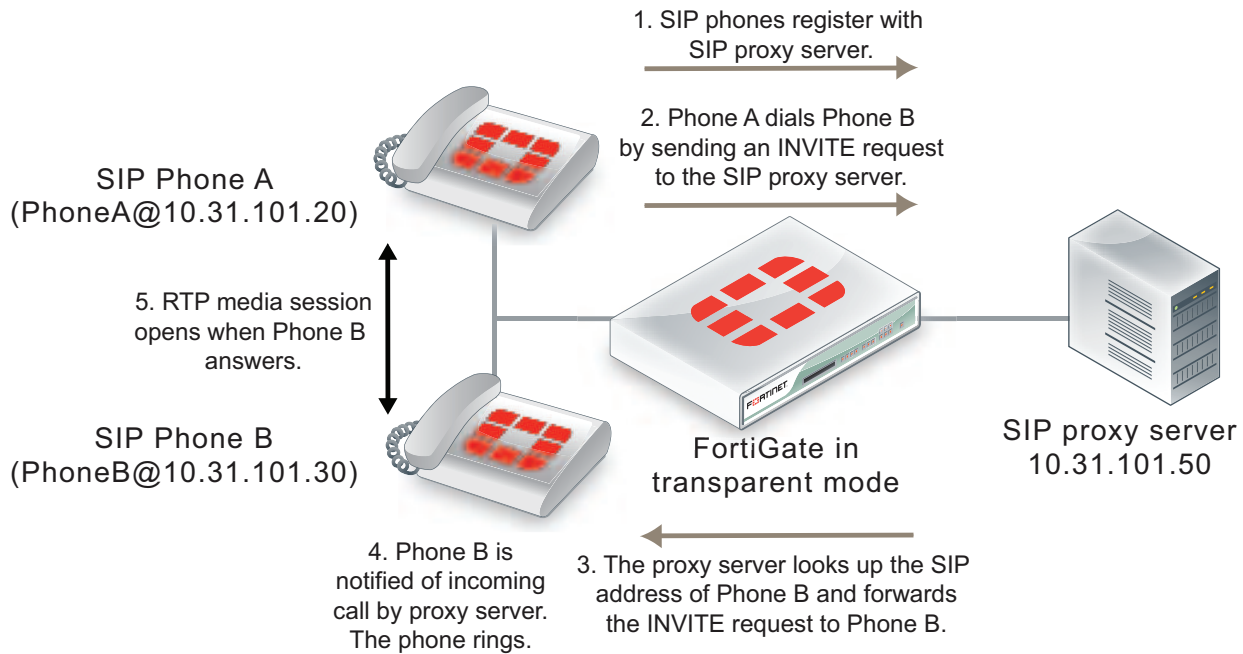

SIP registrar and proxy servers

SIP with a FortiGate

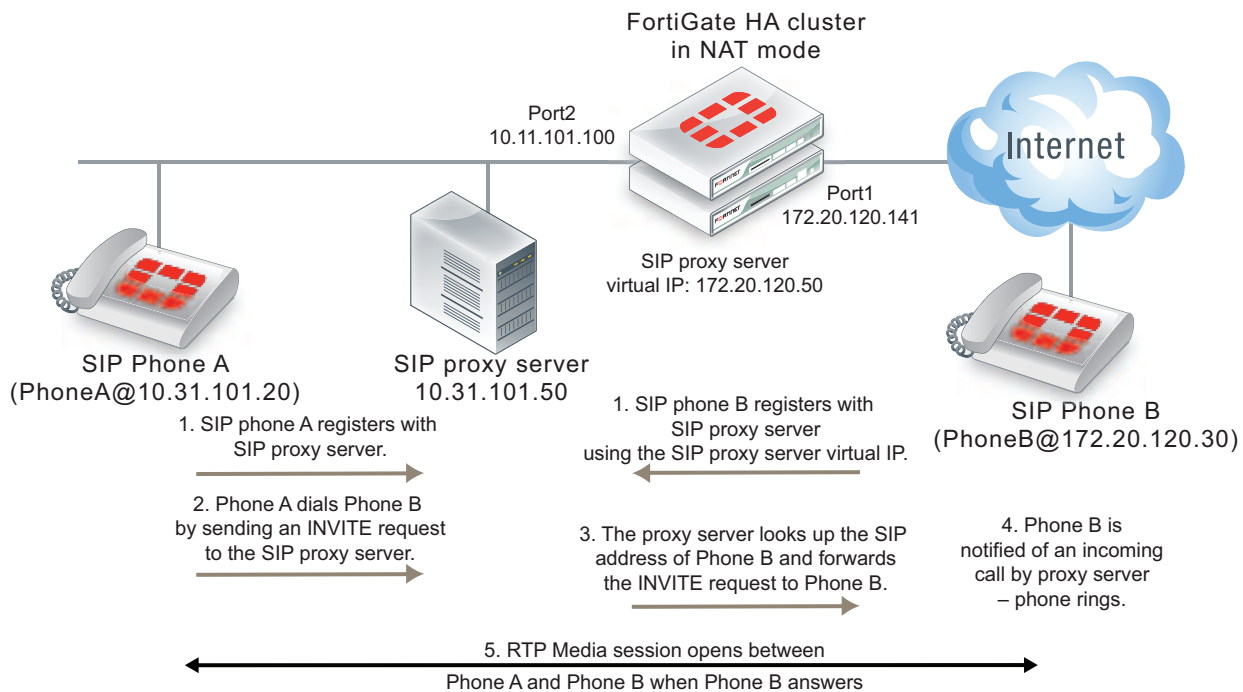

Depending on your security requirements and network configuration FortiGates may be in many different places in a SIP configuration. This section shows a few examples.

The diagram below shows a FortiGate installed between a SIP proxy server and SIP phones on the same network. The FortiGate is operating in transparent mode so both the proxy server and the phones are on the same subnet. In this configuration, called SIP inspection without address translation, the FortiGate could be protecting the SIP proxy server on the private network by implementing SIP security features for SIP sessions between the SIP phones and the SIP proxy server.

SIP network with FortiGate in transparent mode

The phones and server use the same SIP dialogs as they would if the FortiGate was not present. However, the FortiGate can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities.

The following diagram shows a FortiGate operating in NAT/Route mode and installed between a private network and the Internet. Some SIP phones and the SIP proxy server are connected to the private network and some SIP phones are connected to the Internet. The SIP phones on the Internet can connect to the SIP proxy server through the FortiGate and communication between SIP phones on the private network and SIP phones on the Internet must pass through the FortiGate.

SIP network with FortiGate in NAT/Route mode

The phones and server use the same SIP dialog as they would if the FortiGate was not present. However, the FortiGate can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities. In addition, the FortiGate has a firewall virtual IP that forwards packets sent to the SIP proxy server Internet IP address (172.20.120.50) to the SIP proxy server internal network IP address (10.31.101.30).

Since the FortiGate is operating in NAT/Route mode it must translate packet source and destination IP addresses (and optionally ports) as the sessions pass through the FortiGate. Also, the FortiGate must translate the addresses contained in the SIP headers and SDP body of the SIP messages. As well the FortiGate must open SIP and RTP pinholes through the FortiGate. SIP pinholes allow SIP signaling sessions to pass through the FortiGate between phones and between phones and SIP servers. RTP pinholes allow direct RTP communication between the SIP phones once the SIP dialog has established the SIP call. Pinholes are opened automatically by the FortiGate. Administrators do not add security policies for pinholes or for RTP sessions. All that is required is a security policy that accepts SIP traffic.

Opening an RTP pinhole means opening a port on a FortiGate interface to allow RTP traffic to use that port to pass through the FortiGate between the SIP phones on the Internet and SIP phones on the internal network. A pinhole only accepts packets from one RTP session. Since a SIP call involves at least two media streams (one from Phone A to Phone B and one from Phone B to Phone A) the FortiGate opens two RTP pinholes. Phone A sends RTP packets through a pinhole in port2 and Phone B sends RTP packets through a pinhole in port1. The FortiGate opens the pinholes when required by the SIP dialog and closes the pinholes when the SIP call is completed. The FortiGate opens new pinholes for each SIP call.

Each RTP pinhole actually includes two port numbers. The RTP port number as defined in the SIP message and an RTCP port number, which is the RTP port number plus 1. For example, if the SIP call used RTP port 3346 the FortiGate would create a pinhole for ports 3346 and 3347.

SIP messages and media protocols

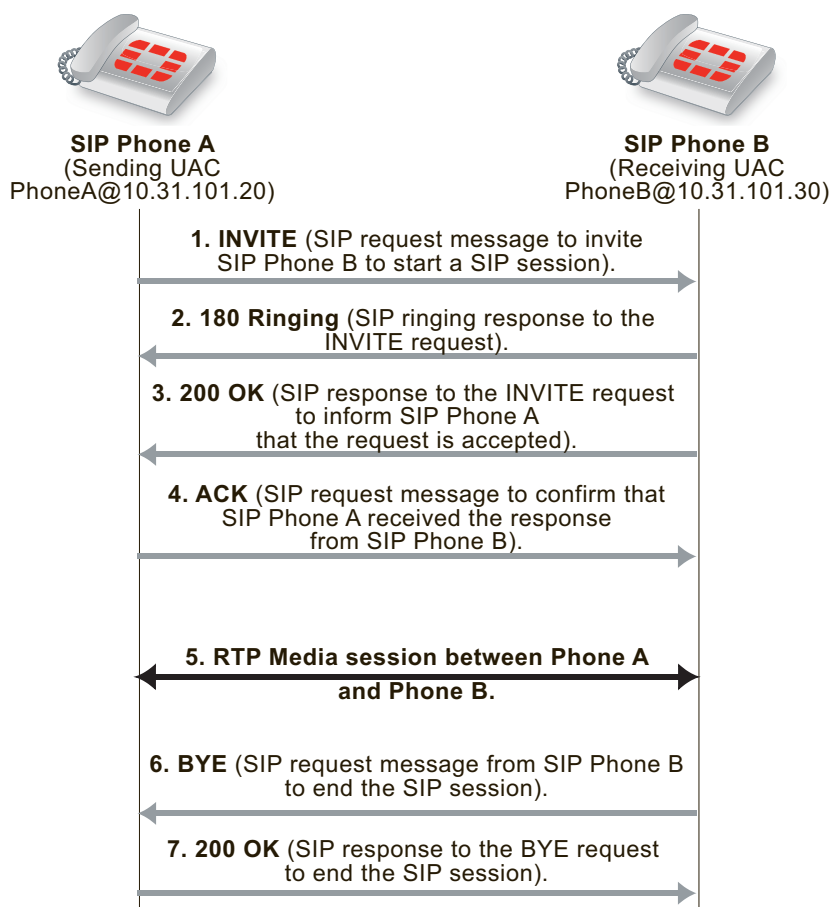

This section provides an overview of SIP messages and how they communicate information about SIP sessions and how SDP, RTP, and RTCP fits in with SIP communications.

SIP uses clear text messages to start, maintain, and end media sessions between SIP user agent clients (UACs) and user agent servers (UASs). These messages form a SIP dialog. A typical SIP dialog begins with an INVITE request message sent from a UAC to another UAC or to a UAS. The first INVITE request message attempts to start a SIP call and includes information about the sending UAC and the receiving UAC as well as information about the communication session.

If only two UACs are involved as shown below, the receiving UAC (Phone B) responds with a 180 Ringing and then a 200 OK SIP response message that informs Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. Phone A and Phone B can then participate in the RTP media session set up by the SIP messages.

When the phone call is complete, one of the UACs (in the example Phone B) hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

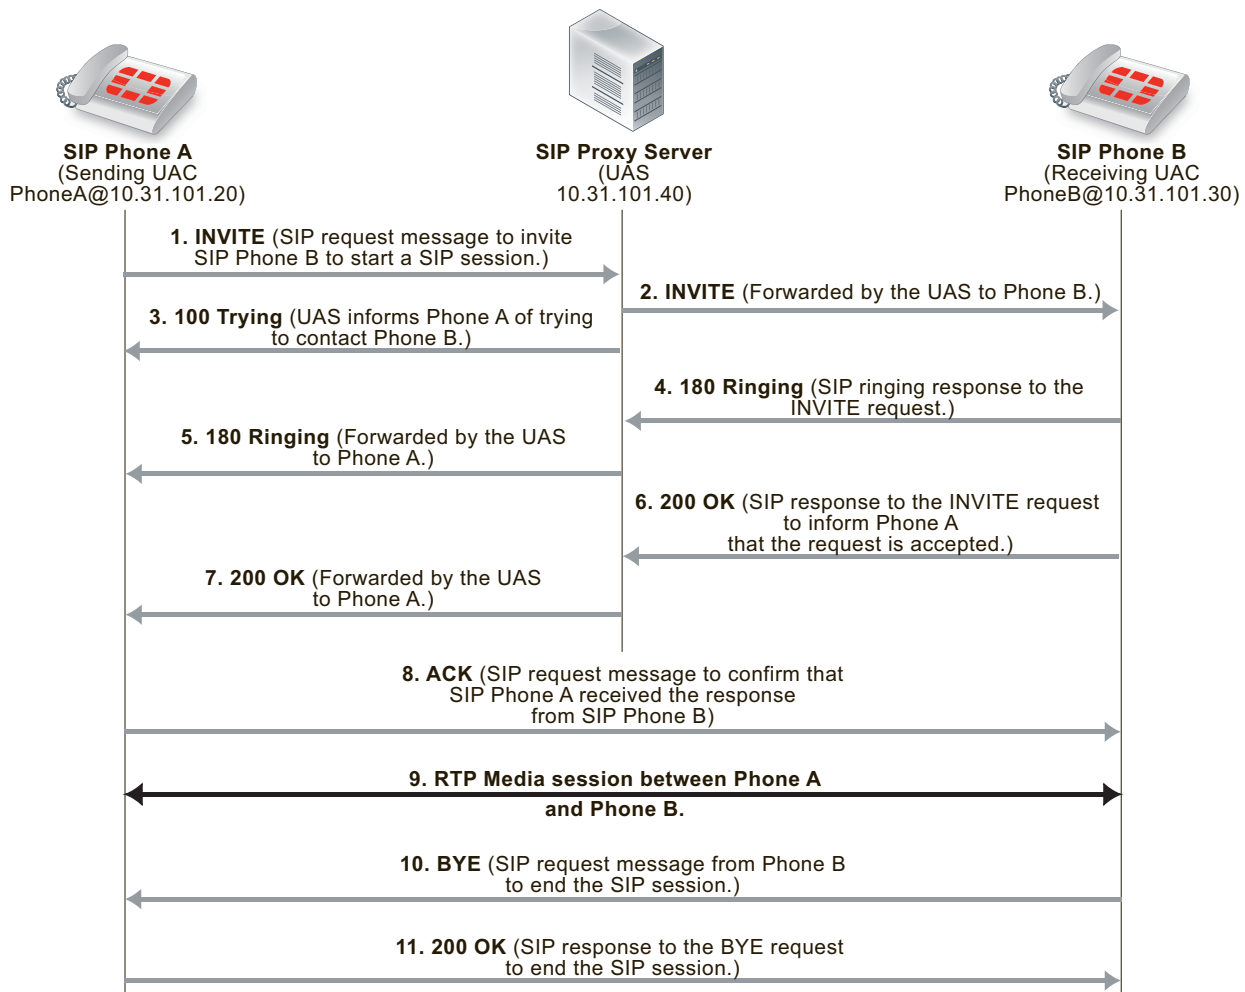

Basic SIP dialog between two UACs

If a UAS in the form of a SIP proxy server is involved, similar messages are sent and received, but the proxy server participates as an intermediary in the initial call setup. In the example below the SIP proxy server receives the INVITE request from Phone A and forwards it to Phone B. The proxy server then sends a 100 Trying response to Phone A. Phone B receives the INVITE request and responds with a 180 Ringing and then a 200 OK SIP response message. These messages are received by the proxy server and forwarded to Phone A to notify Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. This response is received by the proxy server and forwarded to Phone B. Phone A and Phone B can then participate in the media session independently of the proxy server.

When the phone call is complete Phone B hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

Basic SIP dialog between UACs with a SIP proxy server UAS

The SIP messages include SIP headers that contain names and addresses of Phone A, Phone B and the proxy server. This addressing information is used by the UACs and the proxy server during the call set up.

The SIP message body includes Session Description Protocol (SDP) statements that Phone A and Phone B use to establish the media session. The SDP statements specify the type of media stream to use for the session (for example, audio for SIP phone calls) and the protocol to use for the media stream (usually the Real Time Protocol (RTP) media streaming protocol).

Phone A includes the media session settings that it would like to use for the session in the INVITE message. Phone B includes its response to these media settings in the 200 OK response. Phone A's ACK response confirms the settings that Phone A and Phone B then use for the media session.

Hardware accelerated RTP processing

FortiGates can offload RTP packet processing to network processor (NP) interfaces. This acceleration greatly enhances the overall throughput and resulting in near speed RTP performance.

SIP request messages

SIP sessions always start with a SIP request message (also just called a SIP request). SIP request messages also establish, maintain, and terminate SIP communication sessions. The following table lists some common SIP request message types.

Common SIP request message types

Message Type	Description
INVITE	A client sends an INVITE request to invite another client to participate in a multimedia session. The INVITE request body usually contains the description of the session.
ACK	The originator of an INVITE message sends an ACK request to confirm that the final response to an INVITE request was received. If the INVITE request did not contain the session description, it must be included in the ACK request.
PRACK	In some cases, SIP uses provisional response messages to report on the progress of the response to a SIP request message. The provisional response messages are sent before the final SIP response message. Similar to an ACK request message, a PRACK request message is sent to acknowledge that a provisional response message has been received.
OPTIONS	The UA uses OPTIONS messages to get information about the capabilities of a SIP proxy. The SIP proxy server replies with a description of the SIP methods, session description protocols, and message encoding that are supported.
BYE	A client sends a BYE request to end a session. A BYE request from either end of the SIP session terminates the session.
CANCEL	A client sends a CANCEL request to cancel a previous INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE sends a final response to the INVITE before receiving the CANCEL.
REGISTER	A client sends a REGISTER request to a SIP registrar server with information about the current location (IP address and so on) of the client. A SIP registrar server saves the information it receives in REGISTER requests and makes this information available to any SIP client or server attempting to locate the client.

Message Type	Description
Info	For distributing mid-session signaling information along the signaling path for a SIP call. I
Subscribe	For requesting the current state and state updates of a remote node.
Notify	Informs clients and servers of changes in state in the SIP network.
Refer	Refers the recipient (identified by the Request-URI) to a third party according to the contact information in the request.
Update	Opens a pinhole for new or updated SDP information.
Response codes (1xx, 202, 2xx, 3xx, 4xx, 5xx, 6xx)	Indicates the status of a transaction. For example: 200 OK, 202 Accepted, or 400 Bad Request.

SIP response messages

SIP response messages (often just called SIP responses) provide status information in response to SIP request messages. All SIP response messages include a response code and a reason phrase. There are five SIP response message classes. They are described below.

There are also two types of SIP response messages, provisional and final. Final response messages convey the result of the request processing, and are sent reliably. Provisional responses provide information on the progress of the request processing, but may not be sent reliably. Provisional response messages start with 1xx and are also called informational response messages.

Informational (or provisional)

Informational or provisional responses indicate that a request message was received and imply that the endpoint is going to process the request. Information messages may not be sent reliably and may not require an acknowledgment.

If the SIP implementation uses Provisional Response Acknowledgment (PRACK) ([RFC 3262](#)) then informational or provisional messages are sent reliably and require a PRACK message to acknowledge that they have been received.

Informational responses can contain the following reason codes and reason phrases:

```
100 Trying
180 Ringing
181 Call is being forwarded
182 Queued
183 Session progress
```

Success

Success responses indicate that a request message was received, understood, and accepted. Success responses can contain the following reason codes and reason phrases:

```
200 OK
```

202 Accepted

Redirection

Redirection responses indicate that more information is required for the endpoint to respond to a request message. Redirection responses can contain the following reason codes and reason phrases:

300 Multiple choices
301 Moved permanently
302 Moved temporarily
305 Use proxy
380 Alternative service

Client error

Client error responses indicate that a request message was received by a server that contains syntax that the server cannot understand (i.e. contains a syntax error) or cannot comply with. Client error responses include the following reason codes and reason phrases:

400 Bad request	401 Unauthorized
402 Payment required	403 Forbidden
404 Not found	405 Method not allowed
406 Not acceptable	407 Proxy authentication required
408 Request time-out	409 Conflict
410 Gone	411 Length required
413 Request entity too large	414 Request-URL too large
415 Unsupported media type	420 Bad extension
480 Temporarily not available	
481 Call leg/transaction does not exist	
482 Loop detected	
484 Address incomplete	483 Too many hops
486 Busy here	485 Ambiguous
488 Not acceptable here	487 Request canceled

Server error

Server error responses indicate that a server was unable to respond to a valid request message. Server error responses include the following reason codes and reason phrases:

500 Server internal error
501 Not implemented
502 Bad gateway
502 Service unavailable
504 Gateway time-out
505 SIP version not supported

Global failure

Global failure responses indicate that there are no servers available that can respond to a request message. Global failure responses include the following reason codes and reason phrases:

600 Busy everywhere
603 Decline
604 Does not exist anywhere
606 Not acceptable

SIP message start line

The first line in a SIP message is called the start line. The start line in a request message is called the request-line and the start line in a response message is called the status-line.

Request-line	<p>The first line of a SIP request message. The request-line includes the SIP message type, the SIP protocol version, and a Request URI that indicates the user or service to which this request is being addressed. The following example request-line specifies the INVITE message type, the address of the sender of the message (inviter@example.com), and the SIP version:</p> <pre>INVITE sip:inviter@example.com SIP/2.0</pre>
Status-line	<p>The first line of a SIP response message. The status-line includes the SIP protocol version, the response code, and the reason phrase. The example status-line includes the SIP version, the response code (200) and the reason phrase (OK).</p> <pre>SIP/2.0 200 OK</pre>

SIP headers

Following the start line, SIP messages contain SIP headers (also called SIP fields) that convey message attributes and to modify message meaning. SIP headers are similar to HTTP header fields and always have the following format:

```
<header_name>:<value>
```

SIP messages can include the SIP headers listed in the following table:

SIP headers

SIP Header	Description
Allow	<p>Lists the set of SIP methods supported by the UA generating the message. All methods, including ACK and CANCEL, understood by the UA MUST be included in the list of methods in the Allow header field, when present. For example:</p> <pre>Allow: INVITE, ACK, OPTIONS, CANCEL, BYE</pre>
Call-ID	<p>A globally unique identifier for the call, generated by the combination of a random string and the sender's host name or IP address. The combination of the To, From, and Call-ID headers completely defines a peer-to-peer SIP relationship between the sender and the receiver. This relationship is called a SIP dialog.</p> <pre>Call-ID: ddeg45e793@10.31.101.30</pre>

SIP Header	Description
Contact	<p>Included in SIP request messages, the Contact header contains the SIP URI of the sender of the SIP request message. The receiver uses this URI to contact the sender. For example:</p> <pre>Contact: Sender <sip:sender@10.31.100.20>t</pre>
Content-Length	<p>The number of bytes in the message body (in bytes).</p> <pre>Content-Length: 126</pre>
Content-Type	<p>In addition to SIP headers, SIP messages include a message body that contains information about the content or communication being managed by the SIP session. The Content-Type header specifies what the content of the SIP message is. For example, if you are using SIP with SDP, the content of the SIP message is SDP code.</p> <pre>Content-Type: application/sdp</pre>
CSeq	<p>The command sequence header contains a sequence integer that is increased for each new SIP request message (but is not incremented in the response message). This header also includes the request name found in the request message request-line. For example:</p> <pre>CSeq: 1 INVITE</pre>
Expires	<p>Gives the relative time after which the message (or content) expires. The actual time and how the header is used depends on the SIP method. For example:</p> <pre>Expires: 5</pre>
From	<p>Identifies the sender of the message. Responses to a message are sent to the address of the sender. The following example includes the sender's name (<i>Sender</i>) and the sender's SIP address (<i>sender@10.31.101.20</i>):</p> <pre>From: Sender <sip:sender@10.31.101.20></pre>
Max-forwards	<p>An integer in the range 0-255 that limits the number of proxies or gateways that can forward the request message to the next downstream server. Also called the number of hops, this value is decreased every time the message is forwarded. This can also be useful when the client is attempting to trace a request chain that appears to be failing or looping in mid-chain.</p> <pre>For example: Max-Forwards: 30</pre>
P-Asserted-Identity	<p>The P-Asserted-Identity header is used among trusted SIP entities to carry the identity of the user sending a SIP message as it was verified by authentication. See RFC 3325. The header contains a SIP URI and an optional display-name, for example:</p> <pre>P-Asserted-Identity: "Example Person" <sip:10.31.101.50></pre>

SIP Header	Description
RAck	<p>Sent in a PRACK request to support reliability of information or provisional response messages. It contains two numbers and a method tag. For example:</p> <pre>RAck: 776656 1 INVITE</pre>
Record-Route	<p>Inserted into request messages by a SIP proxy to force future requests to be routed through the proxy. In the following example, the host at IP address 10.31.101.50 is a SIP proxy. The <code>lr</code> parameter indicates the URI of a SIP proxy in Record-Route headers.</p> <pre>Record-Route: <sip:10.31.101.50;lr></pre>
Route	<p>Forces routing for a request message through one or more SIP proxies. The following example includes two SIP proxies:</p> <pre>Route: <sip:172.20.120.10;lr>, <sip:10.31.101.50;lr></pre>
RSeq	<p>The RSeq header is used in information or provisional response messages to support reliability of informational response messages. The header contains a single numeric value. For example:</p> <pre>RSeq: 33456</pre>
To	<p>Identifies the receiver of the message. The address in this field is used to send the message to the receiver. The following example includes the receiver's name (<code>Receiver</code>) and the receiver's SIP address (<code>receiver@10.31.101.30</code>):</p> <pre>To: Receiver <sip:receiver@10.31.101.30></pre>
Via	<p>Indicates the SIP version and protocol to be used for the SIP session and the address to which to send the response to the message that contains the Via field. The following example Via field indicates to use SIP version 2, UDP for media communications, and to send the response to 10.31.101.20 using port 5060.</p> <pre>Via: SIP/2.0/UDP 10.31.101.20:5060</pre>

The SIP message body and SDP session profiles

The SIP message body describes the session to be initiated. For example, in a SIP phone call the body usually includes audio codec types, sampling rates, server IP addresses and so on. For other types of SIP session the body could contain text or binary data of any type which relates in some way to the session. The message body is included in request and response messages.

Two possible SIP message body types:

- Session Description Protocol (SDP), most commonly used for SIP VoIP.
- Multipurpose Internet Mail Extensions (MIME)

SDP is most often used for VoIP and FortiGates support SDP content in SIP message bodies. SDP is a text-based protocol used by SIP to control media sessions. SDP does not deliver media but provides a session profile

that contains media details, transport addresses, parameter negotiation, and other session description metadata for the participants in a media session. The participants use the information in the session profile to negotiate how to communicate and to manage the media session. SDP is described by [RFC 4566](#).

An SDP session profile always contains session information and may contain media information. Session information appears at the start of the session profile and media information (using the `m=` attribute) follows.

SDP session profiles can include the attributes listed in the following table.

SDP session profile attributes

Attribute	Description
a=	Attributes to extend SDP in the form <code>a=<attribute></code> or <code>a=<attribute>:<value></code> .
b=	Contains information about the bandwidth required for the session or media in the form <code>b=<bandwidth_type>:<bandwidth></code> .
c=	Connection data about the session including the network type (usually IN for Internet), address type (IPv4 or IPv6), the connection source address, and other optional information. For example: <code>c=IN IPv4 10.31.101.20</code>
i=	A text string that contains information about the session. For example: <code>i=A audio presentation about SIP</code>
k=	Can be used to convey encryption keys over a secure and trusted channel. For example: <code>k=clear:444gdduudjffdee</code>

Attribute	Description
m=	<p>Media information, consisting of one or more lines all starting with m= and containing details about the media including the media type, the destination port or ports used by the media, the protocol used by the media, and a media format description.</p> <pre>m=audio 49170 RTP 0 3 m-video 3345/2 udp 34 m-video 2910/2 RTP/AVP 3 56</pre> <p>Multiple media lines are needed if SIP is managing multiple types of media in one session (for example, separate audio and video streams).</p> <p>Multiple ports for a media stream are indicated using a slash. <code>3345/2 udp</code> means UDP ports 3345 and 3346. Usually RTP uses even-numbered ports for data with the corresponding one-higher odd ports used for the RTCP session belonging to the RTP session. So <code>2910/2 RTP/AVP</code> means ports 2910 and 2912 are used for RTP and 2911 and 2913 are used for RTCP.</p> <p>Media types include <code>udp</code> for an unspecified protocol that uses UDP, <code>RTP</code> or <code>RTP/AVP</code> for standard RTP and <code>RTP/SAVP</code> for secure RTP.</p>
o=	<p>The sender's username, a session identifier, a session version number, the network type (usually IN for Internet), the address type (for example, IPv4 or IPv6), and the sending device's IP address. The o= field becomes a universal identifier for this version of this session description. For example:</p> <pre>o=PhoneA 5462346 332134 IN IP4 10.31.101.20</pre>
r=	<p>Repeat times for a session. Used if a session will be repeated at one or more timed intervals. Not normally used for VoIP calls. The times can be in different formats. For example:</p> <pre>r=7d 1h 0 25h r=604800 3600 0 90000</pre>
s=	<p>Any text that describes the session or s= followed by a space. For example:</p> <pre>s=Call from inviter</pre>
t=	<p>The start and stop time of the session. Sessions with no time restrictions (most VoIP calls) have a start and stop time of 0.</p> <pre>t=0 0</pre>
v=	<p>SDP protocol version. The current SDP version is 0 so the v= field is always:</p> <pre>v=0</pre>
z=	<p>Time zone adjustments. Used for scheduling repeated sessions that span the time between changing from standard to daylight savings time.</p> <pre>z=2882844526 -1h 2898848070 0</pre>

Example SIP messages

The following example SIP INVITE request message was sent by PhoneA to PhoneB. The first nine lines are the SIP headers. The SDP profile starts with v=0 and the media part of the session profile is the last line, starting with m=.

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

The following example shows a possible 200 OK SIP response message in response to the previous INVITE request message. The response includes 200 OK which indicates success, followed by an echo of the original SIP INVITE request followed by PhoneB's SDP profile.

```
SIP/2.0 200 OK
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneB@10.31.101.30
Content-Type: application/sdp
Content-Length: 107
v=0
o=PhoneB 124333 67895 IN IP4 172.20.120.30
s=Hello!
t=0 0
c=IN IP4 172.20.120.30
m=audio 3456 RTP 0
```

SIP can support multiple media streams for a single SIP session. Each media stream will have its own c= and m= lines in the body of the message. For example, the following message includes three media streams:

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.20:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
```

```
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49172 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49174 RTP 0 3
```

The SIP session helper

The SIP session-helper is a high-performance solution that provides basic support for SIP calls passing through the FortiGate by opening SIP and RTP pinholes and by performing NAT of the addresses in SIP messages.

The SIP session helper:

- Understands SIP dialog messages.
- Keeps the states of the SIP transactions between SIP UAs and SIP servers.
- Translates SIP header and SDP information to account for NAT operations performed by the FortiGate.
- Opens up and closes dynamic SIP pinholes for SIP signaling traffic.
- Opens up and closes dynamic RTP and RTSP pinholes for RTP and RTSP media traffic.
- Provides basic SIP security as an access control device.
- Uses the intrusion protection (IPS) engine to perform basic SIP protocol checks.

SIP session helper configuration overview

By default FortiOS uses the SIP ALG for SIP traffic. If you want to use the SIP session helper you need to enter the following commands to disable the SIP ALG and to enable the SIP session helper:

```
config system settings
    set default-voip-alg-mode kernel-helper-based
    set sip-helper enable
end
```

The SIP session helper is disabled by default and must be enabled for the SIP session helper to process VoIP traffic. The SIP session help is set to listen for SIP traffic on TCP or UDP port 5060. SIP sessions using port 5060 accepted by a security policy that does not include a VoIP profile are processed by the SIP session helper.

You might want to disable the SIP session helper and the SIP ALG if you don't want the FortiGate to apply NAT or other SIP session helper features to SIP traffic. With the SIP session helper and the SIP ALG disabled, the FortiGate can still accept SIP sessions if they are allowed by a security policy, but the FortiGate will not be able to open pinholes or NAT the addresses in the SIP messages.

You can enable and disable the SIP session helper, change the TCP or UDP port that the session helper listens on for SIP traffic, and enable or disable SIP NAT tracing. If the FortiGate is operating with multiple VDOMs, each VDOM can have a different SIP session helper configuration.

To have the SIP session helper process SIP sessions you need to add a security policy that accepts SIP sessions on the configured SIP UDP or TCP ports. The security policies can have service set to ANY, or to the SIP pre-defined firewall service, or a custom firewall service. The SIP pre-defined firewall service restricts the security policy to only accepting sessions on UDP port 5060.

If NAT is enabled for security policies that accept SIP traffic, the SIP session helper translates addresses in SIP headers and in the RDP profile and opens up pinholes as required for the SIP traffic. This includes security policies that perform source NAT and security policies that contain virtual IPs that perform destination NAT and port forwarding. No special SIP configuration is required for this address translation to occur, it is all handled automatically by the SIP session helper according to the NAT configuration of the security policy that accepts the SIP session.

To use the SIP session helper you must not add a VoIP profile to the security policy. If you add a VoIP profile, SIP traffic bypasses the SIP session helper and is processed by the SIP ALG.

In most cases you would want to use the SIP ALG since the SIP session helper provides limited functionality. However, the SIP session helper is available and can be useful for high-performance solutions where a high level of SIP security is not a requirement.

Viewing, removing, and adding the SIP session helper configuration

Enter the following command to find the sip session helper entry in the session-helper list:

```
show system session-helper
.
.
.
edit 13
  set name sip
  set port 5060
  set protocol 17
next
.
.
.
```

This command output shows that the sip session helper listens on UDP port 5060 for SIP sessions.

Enter the following command to delete session-helper list entry number 13:

```
config system session-helper
  delete 13
end
```

If you want to use the SIP session helper you can verify whether it is available using the `show system session-helper` command.

If the SIP session helper has been removed from the session-helper list you can use the following command to add it back to the session helper list:

```
config system session-helper
  edit 0
    set name sip
    set port 5060
    set protocol 17
  end
```

Changing the port numbers that the SIP session helper listens on

You can use the following command to change the port number that the SIP session helper listens on for SIP traffic to 5064. The SIP session helper listens on the same port number for UDP and TCP SIP sessions. In this example, the SIP session helper is session helper 13:

```
config system session-helper
  edit 13
    set port 5064
  end
```

The `config system settings options sip-tcp-port, sip-udp-port, and sip-ssl-port` control the ports that the SIP ALG listens on for SIP sessions. See [Changing the port numbers that the SIP ALG listens on on page 3126](#).

Your FortiGate may use a different session helper number for SIP. Enter the following command to view the session helpers:

```
show system session-helper
.
.
.
edit 13
    set name sip
    set port 5060
    set protocol 17
end
.
.
.
```

Configuration example: SIP session helper in transparent mode

The figure below shows an example SIP network consisting of a FortiGate operating in transparent mode between two SIP phones. Since the FortiGate is operating in transparent mode both phones are on the same network and the FortiGate and the SIP session helper does not perform NAT. Even though the SIP session helper is not performing NAT you can use this configuration to apply SIP session helper security features to the SIP traffic.

The FortiGate requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

SIP network with FortiGate in transparent mode

General configuration steps

The following general configuration steps are required for this SIP configuration that uses the SIP session helper. This example includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

This example assumes that you have entered the following command to enable using the SIP session helper:

```
config system settings
    set default-voip-alg-mode kernel-helper-based
end
```

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A.
3. Add a security policy that accepts SIP sessions initiated by Phone B.

Configuration steps - GUI

To add firewall addresses for the SIP phones

1. Go to **Policy & Objects > Addresses**.
2. Select **Create New > Address** to add the following addresses for Phone A and Phone B:

Category	Address
Name	Phone_A
Type	IP/Netmask
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Category	Address
Name	Phone_B
Type	IP/Netmask
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to accept SIP sessions

1. Go to **Policy & Objects > IPv4 Policy**.
2. Select **Create New** to add a security policy.
3. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Incoming Interface	port1
Outgoing Interface	port2
Source	Phone_A
Destination Address	Phone_B
Schedule	always

Service	SIP
Action	ACCEPT

4. Select **OK**.
5. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Incoming Interface	port2
Outgoing Interface	port1
Source Address	Phone_B
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

6. Select **OK**.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to accept SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.
2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall address
  edit Phone_A
    set associated interface port1
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
  edit Phone_B
    set associated interface port2
    set type ipmask
    set subnet 10.31.101.30 255.255.255.255
  end
```

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
  next
  edit 0
    set srcintf port2
```

```
set dstintf port1
set srcaddr Phone_B
set dstaddr Phone_A
set action accept
set schedule always
set service SIP
set utm-status enable
end
```

SIP session helper diagnose commands

You can use the `diagnose sys sip` commands to display diagnostic information for the SIP session helper.

Use the following command to set the debug level for the SIP session helper. Different debug masks display different levels of detail about SIP session helper activity.

```
diagnose sys sip debug-mask <debug_mask_int>
```

Use the following command to display the current list of SIP dialogs being processed by the SIP session help. You can also use the `clear` option to delete all active SIP dialogs being processed by the SIP session helper.

```
diagnose sys sip dialog {clear | list}
```

Use the following command to display the current list of SIP NAT address mapping tables being used by the SIP session helper.

```
diagnose sys sip mapping list
```

Use the following command to display the current SIP session helper activity including information about the SIP dialogs, mappings, and other SIP session help counts. This command can be useful to get an overview of what the SIP session helper is currently doing.

```
diagnose sys sip status
```

The SIP ALG

In most cases you should use the SIP Application Layer Gateway (ALG) for processing SIP sessions. The SIP ALG provides the same basic SIP support as the SIP session helper. Additionally, the SIP ALG provides a wide range of features that protect your network from SIP attacks, apply rate limiting to SIP sessions, check the syntax of SIP and SDP content of SIP messages, and provide detailed logging and reporting of SIP activity.

By default all SIP traffic is processed by the SIP ALG. If the policy that accepts the SIP traffic includes a VoIP profile, the SIP traffic is processed by that profile. If the policy does not include a SIP profile the SIP traffic is processed by the SIP ALG using the default VoIP profile.

If a FortiGate or a VDOM has been configured to use the SIP session helper, you can change this behavior to the default configuration of using the SIP ALG with the following command:

```
config system settings
    set default-voip-alg-mode proxy-based
    set sip-helper disable
end
```

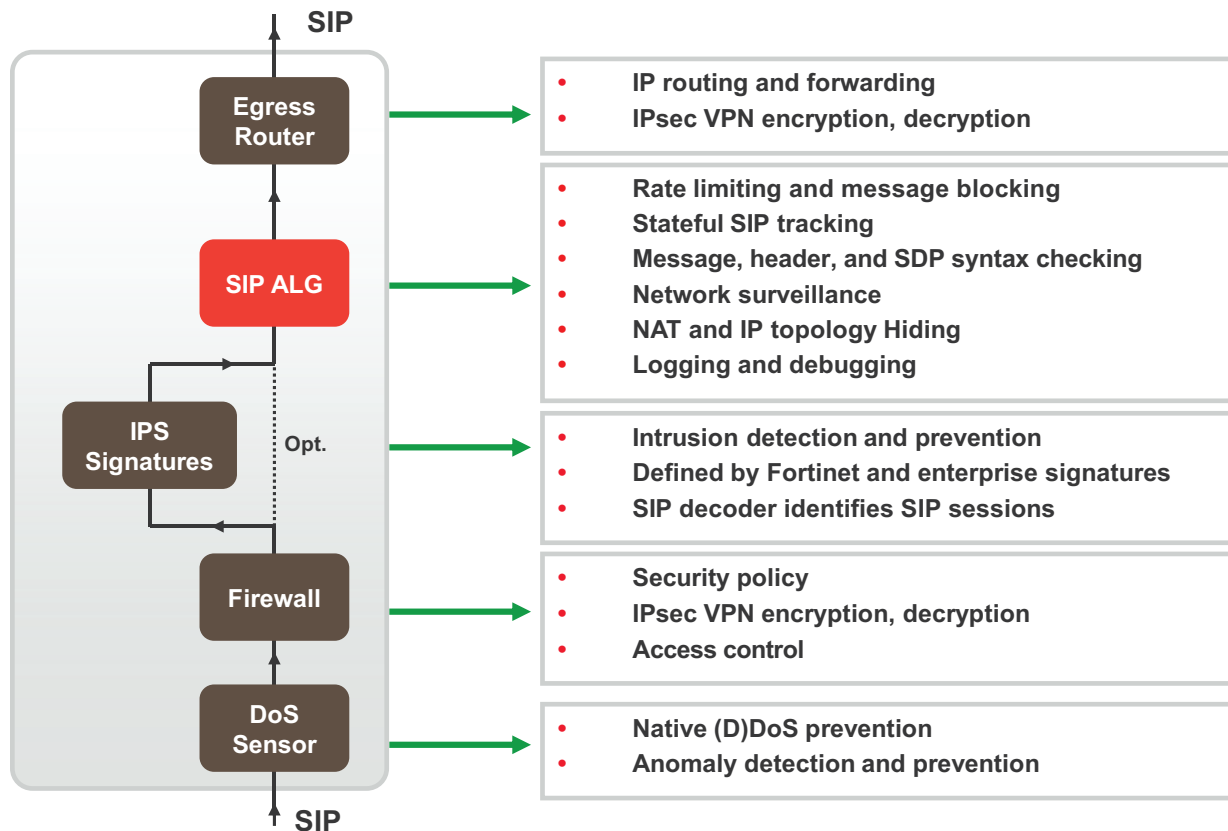

From the GUI you can only configure VoIP security profiles and add them to security policies if VoIP is turned on under **System > Feature Visibility**. However, you can always configure VoIP profiles and add them to security profiles from the CLI. And if the `default-voip-alg` mode is set to `proxy-based` the default SIP profile will still be used even if VoIP security profiles are not visible from the GUI.

As shown in the figure below, the FortiGate SIP ALG intercepts SIP packets after they have been routed by the routing module, accepted by a security policy and passed through DoS and IPS Sensors (if DoS and IPS are enabled). The ALG raises SIP packets to the application layer, analyzes the SIP and SDP addressing information in the SIP messages, makes adjustments (for example, NAT) to this addressing if required, and then sends the packets out the egress interface to their destination.

The SIP ALG provides:

- All the same features as the SIP session helper including NAT and SIP and RTP Pinholes.
- In addition for the ALG you can enable or disable RTP pinholing, SIP register pinholing and SIP contact pinholing. In a signaling only environment where the RTP stream bypasses the FortiGate, you can disable RTP pinholing to improve performance.
- SIP TCP and UDP support
- SIP Message order checking
- Configurable Header line length maximums

The SIP ALG works at the application level after ingress packets are accepted by a security policy

- Message fragment assembly (TCP)
- If SIP messages are fragmented across multiple packets, the FortiGate assembles the fragments, does inspection and pass the message in its entirety to the SIP server as one packet. This offloads the server from doing all the TCP processing of fragments.
- L4 Protocol Translation
- Message Flood Protection
- Protects a SIP server from intentional or unintentional DoS of flooding INVITE, REGISTER, and other SIP methods by allowing control of the rate that these messages pass through the FortiGate.
- SIP message type filtering
- The FortiGate can prevent specified SIP message types from passing through the FortiGate to a SIP server. For example In a voice only SIP implementation, there may be no need to permit a SUBSCRIBE message to ever make it's way to the SIP call processor. Also, if a SIP server cannot process some SIP message types you can use SIP message type filtering to block them. For example, a SIP server could have a bug that prevents it from processing certain SIP messages. In this case you can temporarily block these message types until problem with the SIP server has been fixed.
- SIP statistics and logging
- SIP over IPv6
- SIP over SSL/TLS

- Deep SIP message syntax checking (also called deep SIP header inspection or SIP fuzzing protection). Prevents attacks that use malformed SIP messages. Can check many SIP headers and SDP statements. Configurable bypass and modification options.
- Hosted NAT traversal, Resolves IP address issue in SIP and SDP lines due to NAT-PT in far end firewall. Important feature for VoIP access networks.
- SIP High Availability (HA), including active-passive clustering and session pickup (session failover) for SIP sessions.
- Geographical Redundancy. In an HA configuration, if the active SIP server fails (missing SIP heartbeat messages or SIP traffic) SIP sessions can be redirected to a secondary SIP server in another location.
- SIP per request method message rate limitation with configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.
- RTP Bypass, Supports configurations with and without RTP pinholing. May inspect and protect SIP signaling only.
- SIP NAT with IP address conservation. Performs SIP and RTP aware IP Network Address translation. Preserves the lost IP address information in the SDP profile i= line for later processing/debugging in the SIP server. See [NAT with IP address conservation on page 3159](#).
- IP topology hiding
 - The IP topology of a network can be hidden through NAT and NAPT manipulation of IP and SIP level addressing. For example, see [SIP NAT scenario: source address translation \(source NAT\) on page 3145](#).
- SIP inspection without address translation
 - The SIP ALG inspects SIP messages but addresses in the messages are not translated. This feature can be applied to a FortiGate operating in transparent mode or in NAT/Route mode. In transparent mode you add normal transparent mode security policies that enable the SIP ALG and include a VoIP profile that causes the SIP ALG to inspect SIP traffic as required. For an example configuration, see [Configuration example: SIP in transparent mode on page 3134](#).
- For a FortiGate operating in NAT/Route mode, if SIP traffic can pass between different networks without requiring NAT because is supported by the routing configuration, you can add security policies that accept SIP traffic without enabling NAT. In the VoIP profile you can configure the SIP ALG to inspect SIP traffic as required.

Enabling VoIP support from the GUI

Before you begin to configure VoIP security profiles, including SIP, from the GUI you should go to **System > Feature Visibility** and turn on **VoIP** (under **Additional Features**). VoIP settings are visible in both Inspection modes (flow and proxy).

SIP ALG configuration overview

To apply the SIP ALG, you add a SIP VoIP profile to a security policy that accepts SIP sessions. All SIP sessions accepted by the security policy will be processed by the SIP ALG using the settings in the VoIP profile. The VoIP profile contains settings that are applied to SIP, Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE) and Skinny Call Control Protocol (SCCP) sessions. All SCCP sessions accepted by the security policy are also processed by the ALG. You configure SIP and SCCP settings separately. SIP settings also apply to SIMPLE sessions.

VoIP profiles

You can customize the default VoIP profile or add new VoIP profiles.

To add a new VoIP profile from the GUI go to **Security Profiles > VoIP** and select **Create New** (the + button).

For SIP, from the GUI you can configure the VoIP profile to limit the number of SIP REGISTER and INVITE requests. Many additional options for configuring how the ALG processes SIP sessions are available from the CLI.

For SCCP you can limit the call setup time. Additional SCCP options are available from the CLI.

Use the following command to add a VoIP profile named VoIP_Pro_1 from the CLI:

```
config voip profile
  edit VoIP_Pro_1
end
```

FortiGates include two pre-defined VoIP profiles. On the GUI these profiles look identical. However, the CLI-only settings result in the following functionality.

default	<p>The most commonly used VoIP profile. This profile enables both SIP and SCCP and places the minimum restrictions on what calls will be allowed to negotiate. This profile allows normal SCCP, SIP and RTP sessions and enables the following security settings:</p> <ul style="list-style-type: none"> • <code>strict-register</code> to open smaller more secure pinholes (see Enhancing SIP pinhole security on page 3165). • <code>block-long-lines</code> to block SIP messages with lines that exceed maximum line lengths. • <code>block-unknown</code> to block unrecognized SIP request messages. • <code>open-record-route-pinhole</code> to open pinholes for Record-Route messages. • <code>nat-trace</code> (see NAT with IP address conservation on page 3159). • <code>contact-fixup</code> perform NAT on the IP addresses and port numbers in SIP headers in SIP CONTACT messages even if they don't match the session's IP address and port numbers. • <code>ips-rtp</code> to enable IPS in security policies that also accept SIP sessions to protect the SIP traffic from SIP-based attacks.
strict	<p>This profile is available for users who want to validate SIP messages and to only allow SIP sessions that are compliant with RFC 3261. In addition to the settings in the default VoIP profile, the strict profile sets all SIP deep message inspection header checking options (for example, <code>malformed-request-line</code> and many others) to <code>discard</code>. So the strict profile blocks and drops SIP messages that contain malformed SIP or SDP lines that can be detected by the ALG. For more information about SIP deep header inspection, see Deep SIP message inspection on page 3175.</p>

Neither of the default profiles applies SIP rate limiting. To apply more ALG features to SIP sessions you can clone (copy) the pre-defined VoIP profiles and make your own modifications to them. You can clone VoIP profiles from the GUI or the CLI. For example, from the CLI, to clone the default profile and configure the limit for SIP NOTIFY request messages to 1000 messages per second per security policy and block SIP INFO request messages.

```
config voip profile
  clone default to my_voip_pro
  edit my_voip_pro
    config sip
      set notify-rate 1000
      set block-info enable
    end
  end
```

Changing the port numbers that the SIP ALG listens on

Most SIP configurations use TCP or UDP port 5060 for SIP sessions and port 5061 for SIP SSL sessions. If your SIP network uses different ports for SIP sessions you can use the following command to configure the SIP ALG to listen on a different TCP, UDP, or SSL ports. For example, to change the TCP port to 5064, the UDP port to 5065, and the SSL port to 5066.

```
config system settings
  set sip-tcp-port 5064
  set sip-udp-port 5065
  set sip-ssl-port 5066
end
```

You also configure the SIP ALG to listen in two different TCP ports and two different UDP ports for SIP sessions. For example, if you receive SIP TCP traffic on port 5060 and 5064 and UDP traffic on ports 5061 and 5065 you can enter the following command to receive the SIP traffic on all of these ports:

```
config system settings
  set sip-tcp-port 5060 5064
  set sip-udp-port 5061 5065
end
```

Disabling the SIP ALG in a VoIP profile

SIP is enabled by default in a VoIP profile. If you are just using the VoIP profile for SCCP you can use the following command to disable SIP in the VoIP profile.

```
config voip profile
  edit VoIP_Pro_2
    config sip
      set status disable
    end
```

SIP ALG diagnose commands

You can use the `diagnose sys sip-proxy` command to display diagnostic information for the SIP ALG. A number of options are available including:

Use the following command to list all active SIP calls being processed by the SIP ALG. You can also use the `clear` option to delete all active SIP calls being processed by the SIP ALG, the `idle` option to list idle SIP calls, and the `invite` option to list SIP invite transactions.

```
diagnose sys sip-proxy calls {clear | list | idle | invite}
```

Use the following commands to employ filters to display specific information about the SIP ALG and the session that it is processing. You can build up a filter by including a number of options such as source address, VoIP profile, policy, and so on.

```
diagnose sys sip-proxy filter <filter_options>
```

```
diagnose sys sip-proxy log-filter <filter_options>
```

Use the following command to display the active SIP rate limiting meters and their current settings.

```
diagnose sys sip-proxy meters list
```

Use the following command to display status information about the SIP sessions being processed by the SIP ALG. You can also clear all SIP ALG statistics.

```
diagnose sys sip-proxy stats {clear | list}
```

Conflicts between the SIP ALG and the session helper

If you suspect that the SIP session helper is being used instead of the ALG, you can use the `diagnose sys sip` command to determine if the SIP session helper is processing SIP sessions. For example, the following command displays the overall status of the SIP sessions being processed by the SIP session helper:

The `diagnose sys sip` command only displays current status information. To see activity the SIP session helper has to actually be processing SIP sessions when you enter the command. For example, if the SIP session helper had been used for processing calls that ended 5 minutes ago, the command output would show no SIP session helper activity.

```
diagnose sys sip status
dialogs: max=32768, used=0
mappings: used=0
dialog hash by ID: size=2048, used=0, depth=0
dialog hash by RTP: size=2048, used=0, depth=0
mapping hash: size=2048, used=0, depth=0
count0: 0
count1: 0
count2: 0
count3: 0
count4: 0
```

This command output shows that the session helper is not processing SIP sessions because all of the used and count fields are 0. If any of these fields contains non-zero values then the SIP session helper may be processing SIP sessions.

Also, you can check to see if some ALG-only features are not being applied to all SIP sessions. For example, FortiView pages displays statistics for SIP and SCCP calls processed by the ALG but not for calls processed by the session helper. So if you see fewer calls than expected the session helper may be processing some of them.

Finally, you can check the policy usage and session information dashboard widgets to see if SIP sessions are being accepted by the wrong security policies.

Stateful SIP tracking, call termination, and session inactivity timeout

The SIP ALG tracks SIP dialogs over their lifespan between the first INVITE message and the Final 200 OK and ACK messages. For every SIP dialog, stateful SIP tracking reviews every SIP message and makes adjustment to SIP tracking tables as required. These adjustments include source and destination IP addresses, address translation, dialog expiration information, and media stream port changes. Such changes can also result in dynamically opening and closing pinholes. You can use the `diagnose sys sip-proxy stats list` and the `diagnose sys sip-proxy filter` command to view the SIP call data being tracked by the SIP ALG.

The SIP ALG uses the SIP Expires header line to time out a SIP dialog if the dialog is idle and a Re-INVITE or UPDATE message is not received. The SIP ALG gets the Session-Expires value, if present, from the 200 OK response to the INVITE message. If the SIP ALG receives an INVITE before the session times out, all timeout values are reset to the settings in the new INVITE message or to default values. As a precautionary measure, the SIP ALG uses hard timeout values to set the maximum amount of time a call can exist. This ensures that the FortiGate is protected if a call ends prematurely.

When a SIP dialog ends normally, the SIP ALG deletes the SIP call information and closes open pinholes. A SIP call can also end abnormally due to an unexpected signaling or transport event that cuts off the call. When a call ends abnormally the SIP messages to end the call may not be sent or received. A call can end abnormally for the following reasons:

- Phones or servers crash during a call and a BYE message is not received.
- To attack a SIP system, a malicious user never send a BYE message.
- Poor implementations of SIP fail to process Record-Route messages and never send a BYE message.
- Network failures prevent a BYE message from being received.

Any phone or server in a SIP call can cancel the call by sending a CANCEL message. When a CANCEL message is received by the FortiGate, the SIP ALG closes open pinholes. Before terminating the call, the ALG waits for the final 200 OK message.

The SIP ALG can be configured to terminate SIP calls if the SIP dialog message flow or the call RTP (media) stream is interrupted and does not recover. You can use the following commands to configure terminating inactive SIP sessions and to set timers or counters to control when the call is terminated by the SIP ALG.

Adding a media stream timeout for SIP calls

Use the following command in a VoIP profile to terminate SIP calls accepted by a security policy containing the VoIP profile when the RTP media stream is idle for 100 seconds.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set call-keepalive 100
    end
  end
```

You can adjust this setting between 1 and 10,080 seconds. The default call keepalive setting of 0 disables terminating a call if the media stream is interrupted. Set call keepalive higher if your network has latency problems that could temporarily interrupt media streams. If you have configured call keepalive and the FortiGate terminates calls unexpectedly you can increase the call keepalive time to resolve the problem.

Call keep alive should be used with caution because enabling this feature results in extra FortiGate CPU overhead and can cause delay/jitter for the VoIP call. Also, the FortiGate terminates the call without sending SIP messages to end the call. And if the SIP endpoints send SIP messages to terminate the call they will be blocked by the FortiGate if they are sent after the FortiGate terminates the call.

Adding an idle dialog setting for SIP calls

Use the following command in a VoIP profile to terminate SIP calls when for a single security policy, when the configured number of SIP calls (or dialogs) has stopped receiving SIP messages or has not received legitimate SIP messages. Using this command you can configure how many dialogs that have been accepted by a security policy that the VoIP profile is added to become idle before the SIP ALG deletes the oldest ones. The following command sets the maximum number of idle dialogs to 200:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-idle-dialogs 200
    end
  end
```

Idle dialogs would usually be dialogs that have been interrupted because of errors or problems or as the result of a SIP attack that opens a large number of SIP dialogs without closing them. This command provides a way to remove these dialogs from the dialog table and recover memory and resources being used by these open and idle dialogs.

You can adjust this setting between 1 and a very high number. The default maximum idle dialogs setting of 0 disables this feature. Set maximum dialogs higher if your network has latency problems that could temporarily interrupt SIP messaging. If you have configured max idle dialogs and the FortiGate terminates calls unexpectedly you can increase the max idle dialogs number to resolve the problem.

Changing how long to wait for call setup to complete

In some cases and some configurations your SIP system may experience delays during call setup. If this happens, some SIP ALG timers may expire before call setup is complete and drop the call. In some cases you may also want to reduce the amount of time the SIP ALG allows for call setup to complete.

You can use the `provisional-invite-expiry-time` SIP VoIP profile option to control how long the SIP ALG waits for provisional INVITE messages before assuming that the call setup has been interrupted and the SIP call should be dropped. The default value for this timer is 210 seconds. You can change it to between 10 and 3600 seconds.

Use the following command to change the expiry time to 100 seconds.

```
config voip profile
  edit Profile_name
    config sip
      set provisional-invite-expiry-time 100
    end
  end
```

SIP and RTP/RTCP

FortiGates support the Real Time Protocol (RTP) application layer protocol for the VoIP call audio stream. RTP uses dynamically assigned port numbers that can change during a call. SIP control messages that start a call and that are sent during the call inform callers of the port number to use and of port number changes during the call.

During a call, each RTP session will usually have a corresponding Real Time Control Protocol (RTCP) session. By default, the RTCP session port number is one higher than the RTP port number.

The RTP port number is included in the `m=` part of the SDP profile. In the example above, the SIP INVITE message includes RTP port number is 49170 so the RTCP port number would be 49171. In the SIP response message the RTP port number is 3456 so the RTCP port number would be 3457.

How the SIP ALG creates RTP pinholes

The SIP ALG requires the following information to create a pinhole. The SIP ALG finds this information in SIP messages and some is provided by the SIP ALG:

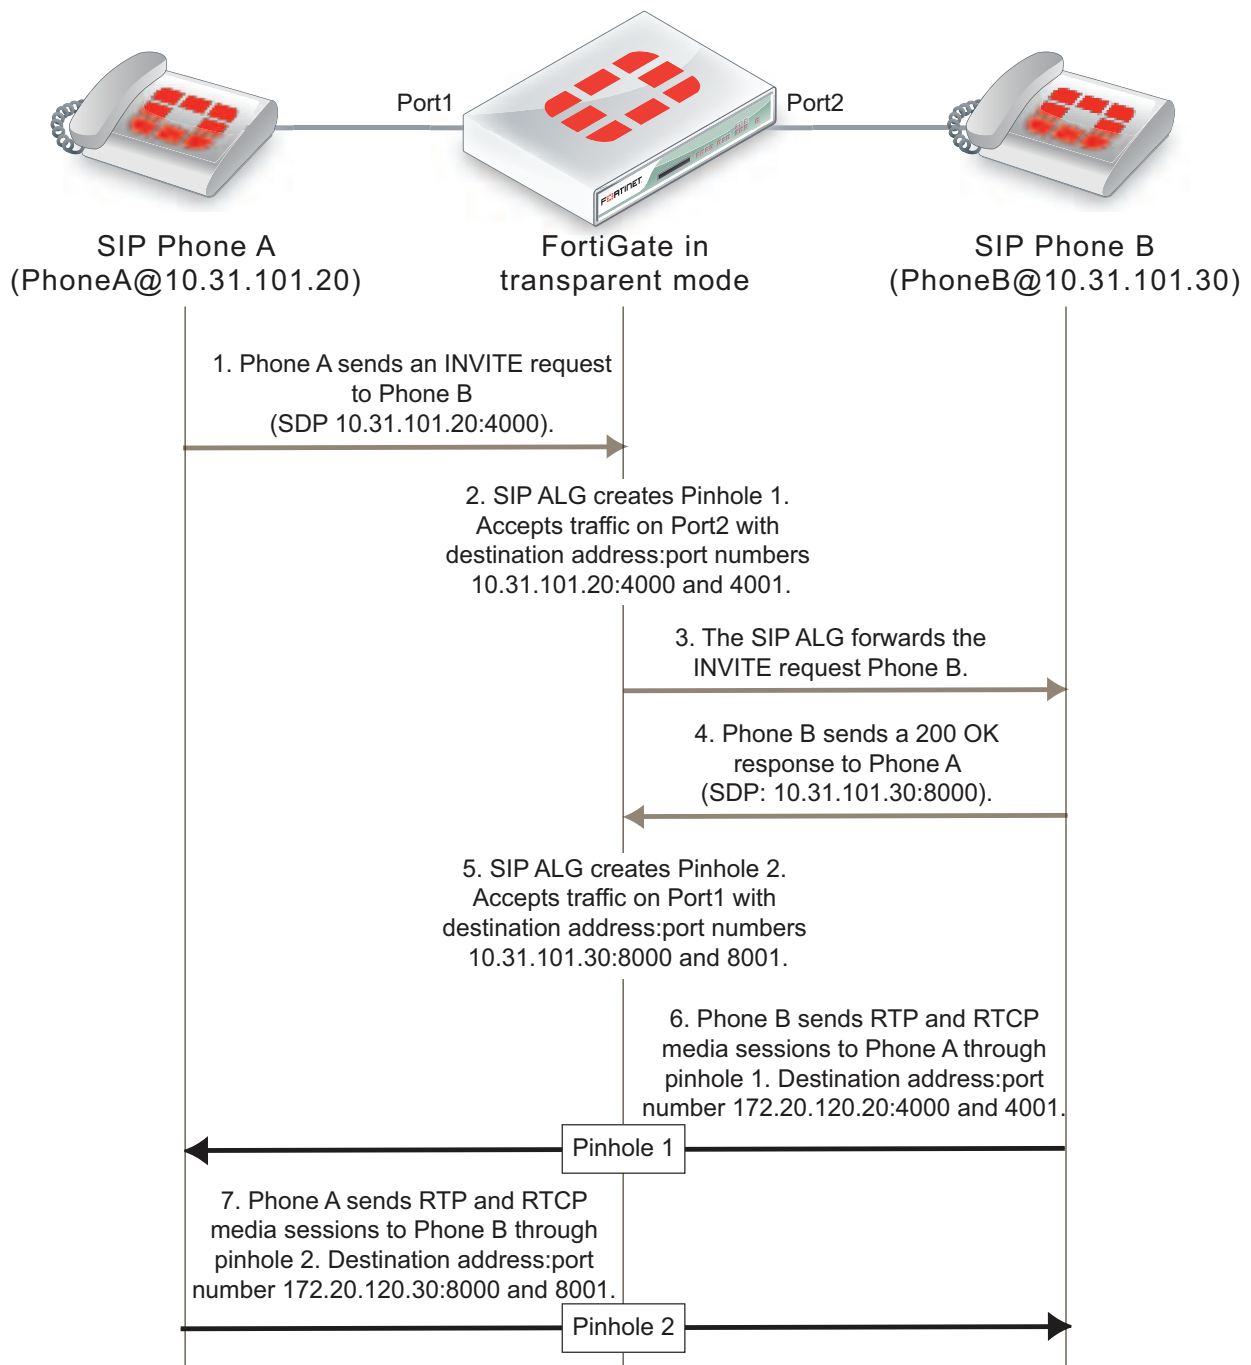

Protocol	UDP (Extracted from SIP messages by the SIP ALG.)
Source IP	Any
Source port	Any
Destination IP	The SIP ALG extracts the destination IP address from the c= line in the SDP profile. The c= line can appear in either the session or media part of the SDP profile. The SIP ALG uses the IP address in the c= line of the media part of the SDP profile first. If the media part does not contain a c= line, the SIP ALG checks the c= line in the session part of the SDP profile. If the session part of the profile doesn't contain a c= line the packet is dropped. Pinholes for RTP and RTCP sessions share the same destination IP address.
Destination port	The SIP ALG extracts the destination port number for RTP from the m= field and adds 1 to this number to get the RTCP port number.
Lifetime	The length of time during which the pinhole will be open. When the lifetime ends, the SIP ALG removes the pinhole.

The SIP ALG keeps RTP pinholes open as long as the SIP session is alive. When the associated SIP session is terminated by the SIP ALG or the SIP phones or servers participating in the call, the RTP pinhole is closed.

The figure below shows a simplified call setup sequence that shows how the SIP ALG opens pinholes. Phone A and Phone B are installed on either side of a FortiGate operating in transparent mode. Phone A and Phone B are on the same subnet. The FortiGate includes a security policy that accepts SIP sessions from port1 to port2 and from port2 to port1. The FortiGate does not require an RTP security policy, just the SIP policy.

You can see from this diagram that the SDP profile in the INVITE request from Phone A indicates that Phone A is expecting to receive a media stream sent to its IP address using port 4000 for RTP and port 4001 for RTCP. The SIP ALG creates pinhole 1 to allow this media traffic to pass through the FortiGate. Pinhole 1 is opened on the Port2 interface and will accept media traffic sent from Phone B to Phone A.

When Phone B receives the INVITE request from Phone A, Phone B will know to send media streams to Phone A using destination IP address 10.31.101.20 and ports 4000 and 4001. The 200 OK response sent from Phone B indicates that Phone B is expecting to receive a media stream sent to its IP address using ports 8000 and 8001. The SIP ALG creates pinhole 2 to allow this media traffic to pass through the FortiGate. Pinhole 2 is opened on the Port1 interface and will accept media traffic sent from Phone A to Phone B.

SIP call setup with a FortiGate in transparent mode

Configuration example: SIP in transparent mode

The figure below shows an example SIP network consisting of a FortiGate operating in transparent mode between two SIP phones. Since the FortiGate is operating in transparent mode both phones are on the same network and the FortiGate and the SIP ALG does not perform NAT. Even though the SIP ALG is not performing NAT you can use this configuration to apply SIP security features to the SIP traffic.

The FortiGate requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

SIP network with FortiGate in transparent mode

General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the security service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - GUI

Before you begin this procedure you may have to go to **System > Feature Visibility** and turn on VoIP.

To add firewall addresses for the SIP phones

1. Go to **Policy & Objects > Addresses**.
2. Add the following addresses for Phone A and Phone B:

Category	Address
Name	Phone_A
Type	IP/Netmask
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Category	Address
Name	Phone_B
Type	IP/Netmask
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to apply the SIP ALG to SIP sessions

1. Go to **Policy & Objects > IPv4 Policy**.
2. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Incoming Interface	port1
Outgoing Interface	port2
Source	Phone_A
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

3. Turn on **VoIP** and select the **default** VoIP profile.
4. Select **OK**.
5. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Incoming Interface	port2
Outgoing Interface	port1
Source	Phone_B
Destination Address	Phone_A

Schedule	always
Service	SIP
Action	ACCEPT

6. Turn on **VoIP** and select the **default** VoIP profile.
7. Select **OK**.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
edit Phone_A
set associated-interface port1
set type ipmask
set subnet 10.31.101.20 255.255.255.255
next
edit Phone_B
set associated-interface port2
set type ipmask
set subnet 10.31.101.30 255.255.255.255
end
```

2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
edit 0
set srcintf port1

RTP enable/disable (RTP bypass)

You can configure the SIP ALG to stop from opening RTP pinholes. Called RTP bypass, this configuration can be used when you want to apply SIP ALG features to SIP signaling messages but do not want the RTP media streams to pass through the FortiGate. The FortiGate only acts as a signaling firewall and RTP media session bypass the FortiGate and no pinholes need to be created.

Enter the following command to enable RTP bypass in a VoIP profile by disabling opening RTP pinholes:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set rtp disable
    end
  end
```

Opening and closing SIP register, contact, via and record-route pinholes

You can use the `open-register-pinhole`, `open-contact-pinhole`, `open-via-port`, and `open-record-route-pinhole` VoIP profile CLI options to control whether the FortiGate opens various pinholes.

If `open-register-pinhole` is enabled (the default setting) the FortiGate opens pinholes for SIP Register request messages. You can disable `open-register-pinhole` so that the FortiGate does not open pinholes for SIP Register request messages.

If `open-contact-pinhole` is enabled (the default setting) the FortiGate opens pinholes for non-Register SIP request messages. You can disable `open-contact-pinhole` so that the FortiGate does not open pinholes for non-register requests. Non-register pinholes are usually opened for SIP INVITE requests.

If `open-via-pinhole` is disabled (the default setting) the FortiGate does not open pinholes for Via messages. You can enable `open-via-pinhole` so that the FortiGate opens pinholes for Via messages.

If `open-record-route-pinhole` is enabled (the default setting) the FortiGate opens pinholes for Record-Route messages. You can disable `open-record-route-pinhole` so that the FortiGate does not open pinholes for Record-Route messages.

Usually you would want to open these pinholes. Keeping them closed may prevent SIP from functioning properly through the FortiGate. They can be disabled, however, for interconnect scenarios (where all SIP traffic is between proxies and traveling over a single session). In some cases these settings can also be disabled in access scenarios if it is known that all users will be registering regularly so that their contact information can be learned from the register request.

You might want to prevent pinholes from being opened to avoid creating a pinhole for every register or non-register request. Each pinhole uses additional system memory, which can affect system performance if there are hundreds or thousands of users, and requires refreshing which can take a relatively long amount of time if there are thousands of active calls.

To configure a VoIP profile to prevent opening register and non-register pinholes:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set open-register-pinhole disable
      set open-contact-pinhole disable
    end
  end
```

In some cases you may not want to open pinholes for the port numbers specified in SIP Contact headers. For example, in an interconnect scenario when a FortiGate is installed between two SIP servers and the only SIP traffic through the FortiGate is between these SIP servers pinholes may not need to be opened for the port numbers specified in the Contact header lines.

If you disable `open-register-pinhole` then pinholes are not opened for ports in Contact header lines in SIP Register messages. If you disable `open-contact-pinhole` then pinholes are not opened for ports in Contact header lines in all SIP messages except SIP Register messages.

Accepting SIP register responses

You can enable the VoIP profile `open-via-pinhole` options to accept a SIP Register response message from a SIP server even if the source port of the Register response message is different from the destination port.

Most SIP servers use 5060 as the source port in the SIP register response. Some SIP servers, however, may use a different source port. If your SIP server uses a different source port, you can enable `open-via-pinhole` and the SIP ALG will create a temporary pinhole when the Register request from a SIP client includes a different source port. The FortiGate will accept a SIP Register response with any source port number from the SIP server.

Enter the following command to enable accepting any source port from a SIP server:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set open-via-pinhole enable
    end
  end
end
```

How the SIP ALG performs NAT

In most Network Address Translation (NAT) configurations, multiple hosts in a private network share a single public IP address to access the Internet. For sessions originating on the private network for the Internet, NAT replaces the private IP address of the PC in the private subnet with the public IP address of the NAT device. The NAT device converts the public IP address for responses from the Internet back into the private address before sending the response over the private network to the originator of the session.

Using NAT with SIP is more complex because of the IP addresses and media stream port numbers used in SIP message headers and bodies. When a caller on the private network sends a SIP message to a phone or SIP server on the Internet, the SIP ALG must translate the private network addresses in the SIP message to IP addresses and port numbers that are valid on the Internet. When the response message is sent back to the caller, the SIP ALG must translate these addresses back to valid private network addresses.

In addition, the media streams generated by the SIP session are independent of the SIP message sessions and use varying port numbers that can also change during the media session. The SIP ALG opens pinholes to accept these media sessions, using the information in the SIP messages to determine the pinholes to open. The ALG may also perform port translation on the media sessions.

When an INVITE message is received by the SIP ALG, the FortiGate extracts addressing and port number information from the message header and stores it in a SIP dialog table. Similar to an IP session table the data in the dialog table is used to translate addresses in subsequent SIP messages that are part of the same SIP call.

When the SIP ALG receives a response to the INVITE message arrives, (for example, an ACK or 200 OK), the SIP ALG compares the addresses in the message fields against the entries in the SIP dialog table to identify the call context of the message. The SIP ALG then translates addresses in the SIP message before forwarding them to their destination.

The addressing and port number information in SDP fields is used by the ALG to reserve ports for the media session and create a NAT mapping between them and the ports in the SDP fields. Because SDP uses sequential ports for the RTP and RTCP channels, the ALG provides consecutive even-odd ports.

SIP ALG source address translation

When a SIP call is started by a phone on a private network destined for a phone on the Internet, only source address translation is required. The phone on the private network attempts to contact the actual IP address of the phone on the Internet. However, the source address of the phone on the private network is not routable on the Internet so the SIP ALG must translate all private IP addresses in the SIP message into public IP addresses.

To configure the FortiGate for source address translation you add security policy that accepts sessions from the internal network destined for the Internet. You must enable NAT for the security policy and add a VoIP profile.

When a SIP request is received from the internal to the external network, the SIP ALG replaces the private network IP addresses and port numbers in the SIP message with the IP address of the FortiGate interface connected to the Internet. Depending on the content of the message, the ALG translates addresses in the Via:, Contact:, Route:, and Record-Route: SIP header fields. The message is then forwarded to the destination (either a VoIP phone or a SIP server on the Internet).

The VoIP phone or server in the Internet sends responses to these SIP messages to the external interface of the FortiGate. The addresses in the response messages are translated back into private network addresses and the response is forwarded to the originator of the request.

For the RTP communication between the SIP phones, the SIP ALG opens pinholes to allow media through the FortiGate on the dynamically assigned ports negotiated based on information in the SDP and the Via:, Contact:, and Record-Route: header fields. The pinholes also allow incoming packets to reach the Contact:, Via:, and Record-Route: IP addresses and ports. When processing return traffic, the SIP ALG inserts the original Contact:, Via:, Route:, and Record-Route: SIP fields back into the packets.

SIP ALG destination address translation

Incoming calls are directed from a SIP phone on the Internet to the interface of the FortiGate connected to the Internet. To receive these calls you must add a security policy to accept SIP sessions from the Internet. The security policy requires a firewall virtual IP. SIP INVITE messages from the Internet connect to the external IP address of the virtual IP. The SIP ALG uses the destination address translation defined in the virtual IP to translated the addresses in the SIP message to addresses on the private network.

When a 200 OK response message arrives from the private network, the SIP ALG translates the addresses in the message to Internet addresses and opens pinholes for media sessions from the private network to the Internet.

When the ACK message is received for the 200 OK, it is also intercepted by the SIP ALG. If the ACK message contains SDP information, the SIP ALG checks to determine if the IP addresses and port numbers are not changed from the previous INVITE. If they are, the SIP ALG deletes pinholes and creates new ones as required. The ALG also monitors the Via:, Contact:, and Record-Route: SIP fields and opens new pinholes as required.

SIP call re-invite messages

SIP Re-INVITE messages can dynamically add and remove media sessions during a call. When new media sessions are added to a call the SIP ALG opens new pinholes and update SIP dialog data. When media sessions are ended, the SIP ALG closes pinholes that are no longer needed and removes SIP dialog data.

How the SIP ALG translates IP addresses in SIP headers

The SIP ALG applies NAT to SIP sessions by translating the IP addresses contained in SIP headers. For example, the following SIP message contains most of the SIP fields that contain addresses that need to be translated:

```
INVITE PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 172.20.120.50:5434
From: PhoneA@10.31.101.20
To: PhoneB@172.20.120.30
Call-ID: a12abcde@172.20.120.50
Contact: PhoneA@10.31.101.20:5434
Route: <sip:example@172.20.120.50:5060>
Record-Route: <sip:example@172.20.120.50:5060>
```

How IP address translation is performed depends on whether source NAT or destination NAT is applied to the session containing the message:

Source NAT translation of IP addresses in SIP messages

Source NAT translation occurs for SIP messages sent from a phone or server on a private network to a phone or server on the Internet. The source addresses in the SIP header fields of the message are typically set to IP addresses on the private network. The SIP ALG translates these addresses to the address the FortiGate interface connected to the Internet.

Source NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	None
From:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Call-ID:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Via:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Request-URI:	None
Contact:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Record-Route:	Replace private network address with IP address of FortiGate interface connected to the Internet.
Route:	Replace private network address with IP address of FortiGate interface connected to the Internet.

Response messages from phones or servers on the Internet are sent to the FortiGate interface connected to the Internet where the destination addresses are translated back to addresses on the private network before forwarding the SIP response message to the private network.

Source NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None
From:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Call-ID:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Via:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Request-URI:	N/A
Contact:	None

SIP header	NAT action
Record-Route:	Replace IP address of FortiGate interface connected to the Internet with private network address.
Route:	Replace IP address of FortiGate interface connected to the Internet with private network address.

Destination NAT translation of IP addresses in SIP messages

Destination NAT translation occurs for SIP messages sent from a phone or server on the Internet to a firewall virtual IP address. The destination addresses in the SIP header fields of the message are typically set to the virtual IP address. The SIP ALG translates these addresses to the address of a SIP server or phone on the private network on the other side of the FortiGate.

Destination NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
From:	None
Call-ID:	None
Via:	None
Request-URI:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
Contact:	None
Record-Route:	None
Route:	None

SIP response messages sent in response to the destination NAT translated messages are sent from a server or a phone on the private network back to the originator of the request messages on the Internet. These reply messages are accepted by the same security policy that accepted the initial request messages. The firewall VIP in the original security policy contains the information that the SIP ALG uses to translate the private network source addresses in the SIP headers into the firewall virtual IP address.

Destination NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None

SIP header	NAT action
From:	Replace private network address with firewall VIP address.
Call-ID:	None
Via:	None
Request-URI:	N/A
Contact:	Replace private network address with firewall VIP address.
Record-Route:	Replace private network address with firewall VIP address.
Route:	None

How the SIP ALG translates IP addresses in the SIP body

The SDP session profile attributes in the SIP body include IP addresses and port numbers that the SIP ALG uses to create pinholes for the media stream.

The SIP ALG translates IP addresses and port numbers in the `o=`, `c=`, and `m=` SDP lines. For example, in the following lines the ALG could translate the IP addresses in the `o=` and `c=` lines and the port number (49170) in the `m=` line.

```
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

If the SDP session profile includes multiple RTP media streams, the SIP ALG opens pinholes and performs the required address translation for each one.

The two most important SDP attributes for the SIP ALG are `c=` and `m=`. The `c=` attribute is the connection information attribute. This field can appear at the session or media level. The syntax of the connection attribute is:

```
c=IN {IPv4 | IPv6} <destination_ip_address>
```

Where

- `IN` is the network type. FortiGates support the `IN` or Internet network type.
- `{IPv4 | IPv6}` is the address type. FortiGates support IPv4 or IPv6 addresses in SDP statements. However, FortiGates do not support all types of IPv6 address translation. See [SIP over IPv6 on page 3174](#).
- `<destination_IP_address>` is the unicast numeric destination IP address or domain name of the connection in either IPv4 or IPv6 format.

The syntax of the media attribute is:

```
m=audio <port_number> RTP <format_list>
```

Where

- `audio` is the media type. FortiGates support the `audio` media type.
- `<port_number>` is the destination port number used by the media stream.
- `RTP` is the application layer transport protocol used for the media stream. FortiGates support the Real Time Protocol (RTP) transport protocol.

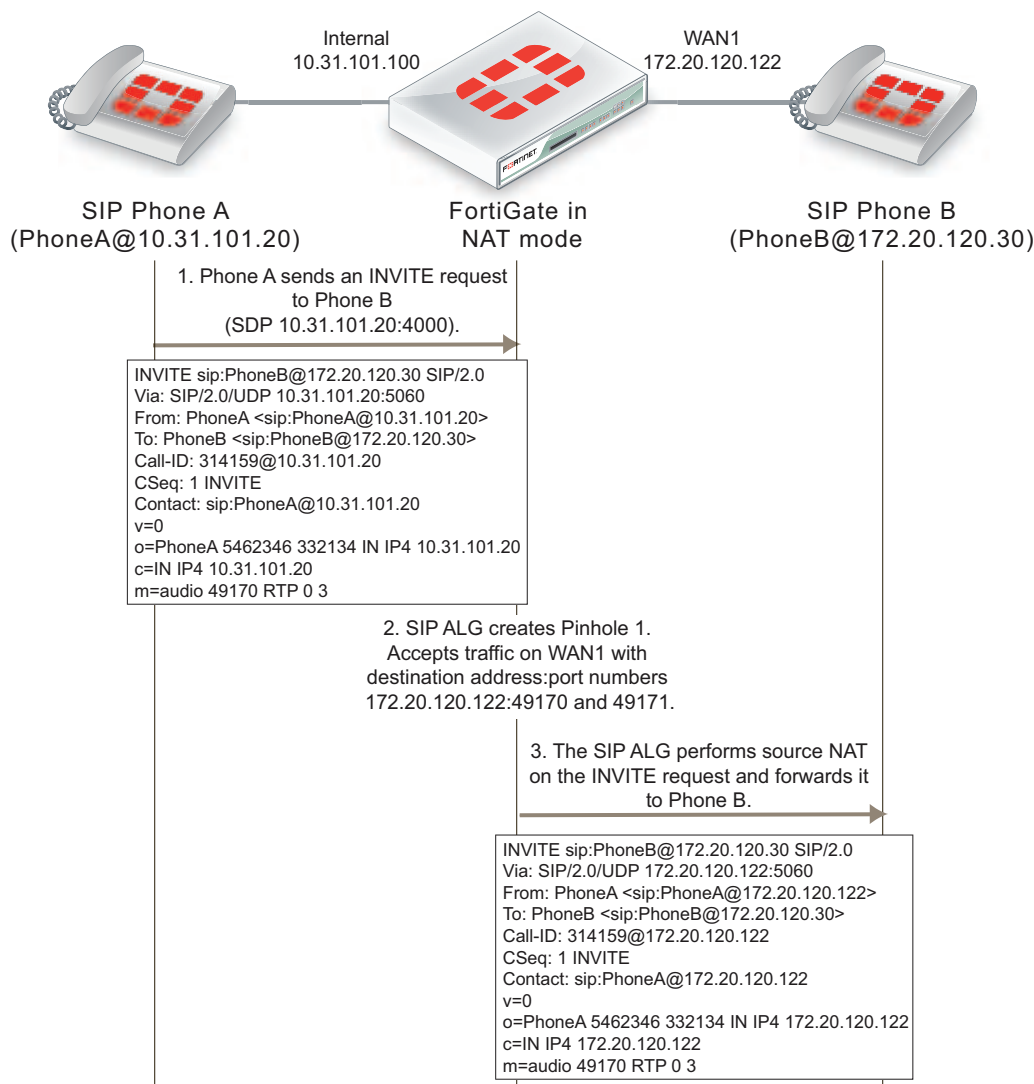

- `<format_list>` is the format list that provides information about the application layer protocol that the media uses.

SIP NAT scenario: source address translation (source NAT)

The following figures show a source address translation scenario involving two SIP phones on different networks, separated by a FortiGate. In the scenario, SIP Phone A sends an INVITE request to SIP Phone B and SIP Phone B replies with a 200 OK response and then the two phones start media streams with each other.

To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

SIP source NAT scenario part 1: INVITE request sent from Phone A to Phone B

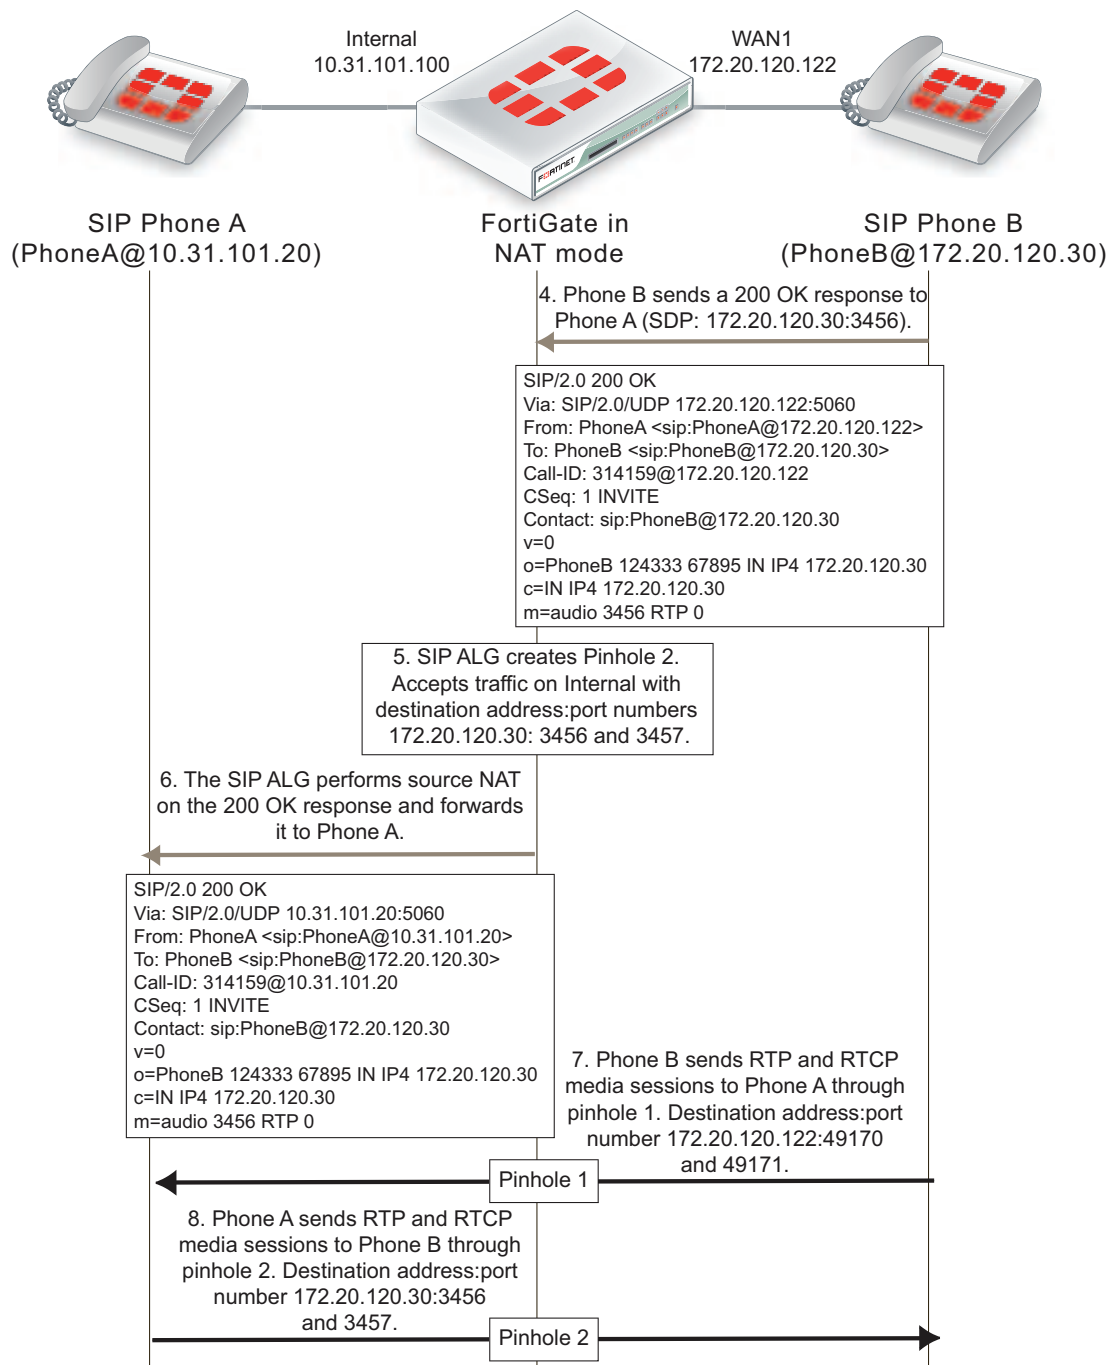

For the replies to SIP packets sent by Phone A to be routable on Phone B's network, the FortiGate uses source NAT to change their source address to the address of the WAN1 interface. The SIP ALG makes similar changes to the source addresses in the SIP headers and SDP profile. For example, the original INVITE request from Phone A includes the address of Phone A (10.31.101.20) in the from header line. After the INVITE request passes through

the FortiGate, the address of Phone A in the From SIP header line is translated to 172.20.120.122, the address of the FortiGate WAN1 interface. As a result, Phone B will reply to SIP messages from Phone A using the WAN1 interface IP address.

The FortiGate also opens a pinhole so that it can accept media sessions sent to the WAN1 IP address using the port number in the m= line of the INVITE request and forward them to Phone A after translating the destination address to the IP address of Phone A.

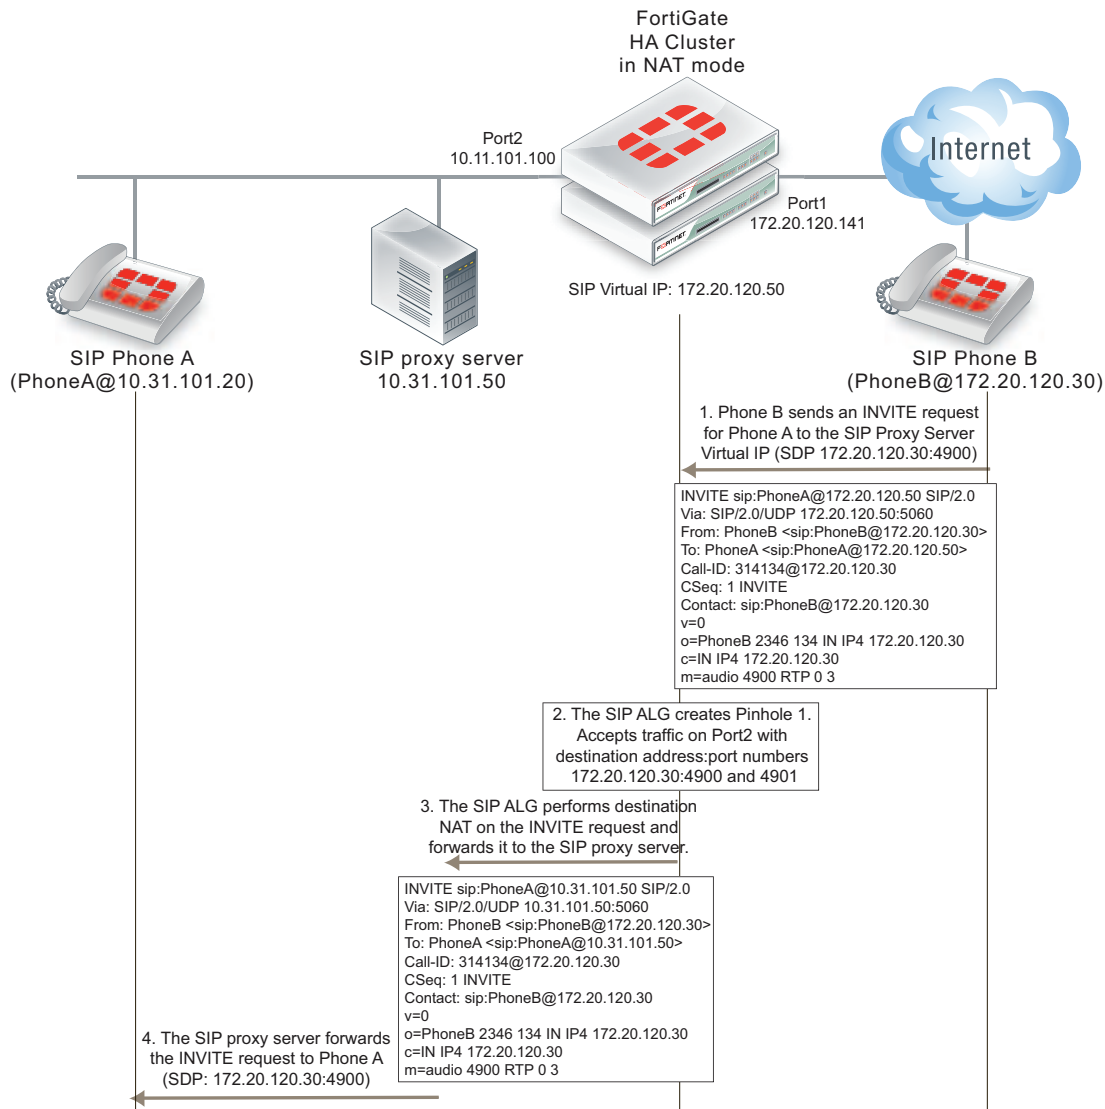

Phone B sends the 200 OK response to the INVITE message to the WAN1 interface. The SDP profile includes the port number that Phone B wants to use for its media stream. The FortiGate forwards 200 OK response to Phone A after translating the addresses in the SIP and SDP lines back to the IP address of Phone A. The SIP ALG also opens a pinhole on the Internal interface that accepts media stream sessions from Phone A with destination address set to the IP address of Phone B and using the port that Phone B added to the SDP m= line.

SIP source NAT scenario part 2: 200 OK returned and media streams established**SIP NAT scenario: destination address translation (destination NAT)**

The following figures show how the SIP ALG translates addresses in a SIP INVITE message sent from SIP Phone B on the Internet to SIP Phone A on a private network using the SIP proxy server. Because the addresses on the private network are not visible from the Internet, the security policy on the FortiGate that accepts SIP sessions

includes a virtual IP. Phone A sends SIP the INVITE message to the virtual IP address. The FortiGate accepts the INVITE message packets and using the virtual IP, translates the destination address of the packet to the IP address of the SIP proxy server and forwards the SIP message to it.

SIP destination NAT scenario part 1: INVITE request sent from Phone B to Phone A

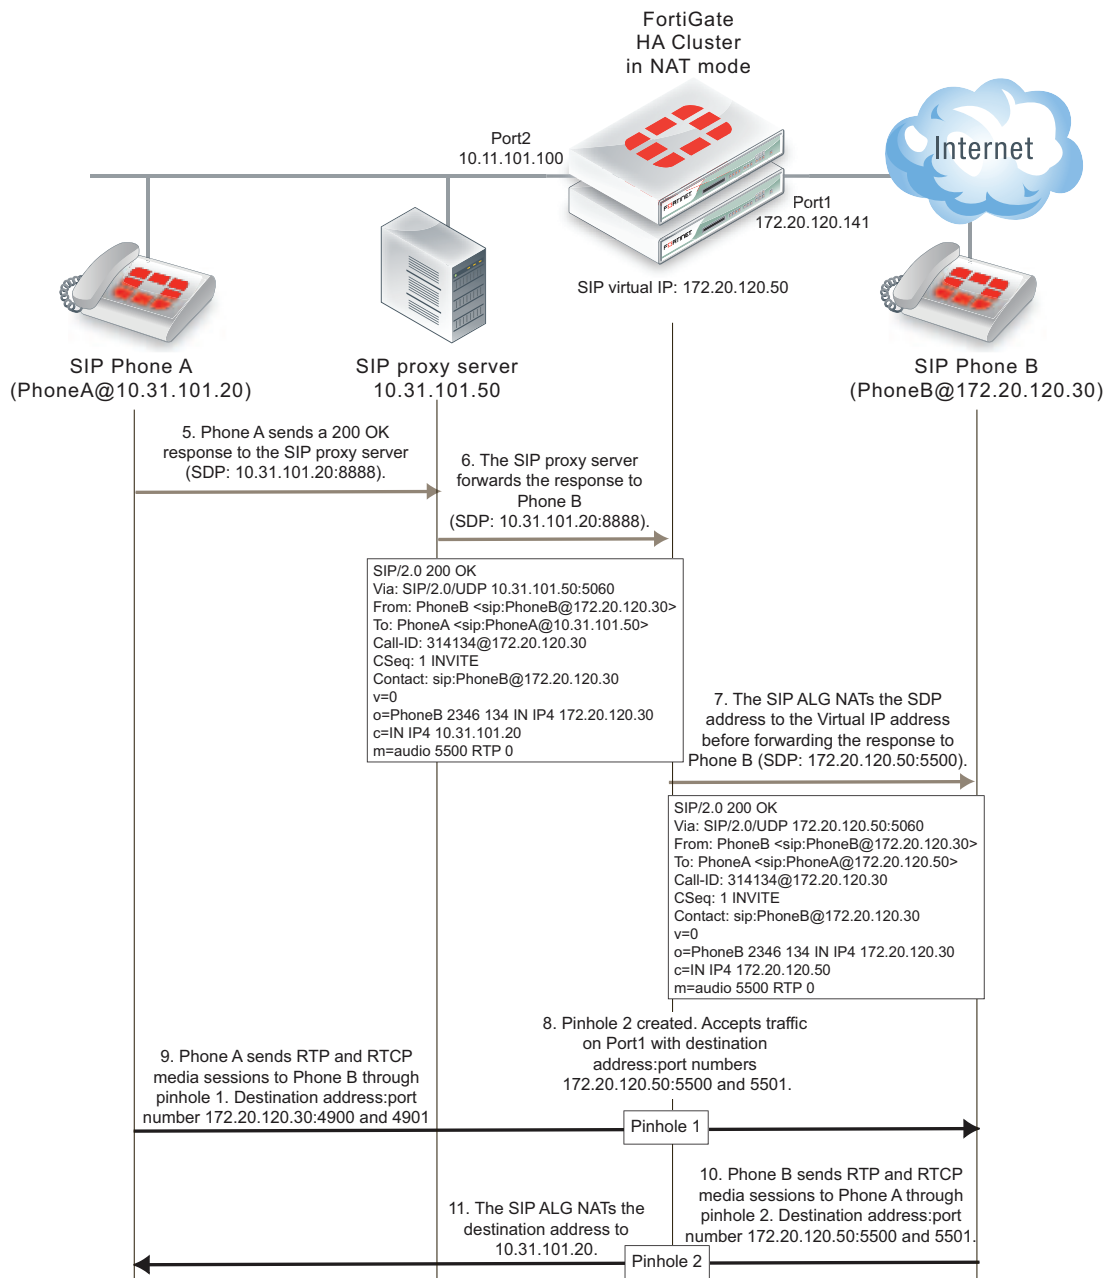

To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

The SIP ALG also translates the destination addresses in the SIP message from the virtual IP address (172.20.120.50) to the SIP proxy server address (10.31.101.50). For this configuration to work, the SIP proxy server must be able to change the destination addresses for Phone A in the SIP message from the address of the SIP proxy server to the actual address of Phone A.

The SIP ALG also opens a pinhole on the Port2 interface that accepts media sessions from the private network to SIP Phone B using ports 4900 and 4901.

Phone A sends a 200 OK response back to the SIP proxy server. The SIP proxy server forwards the response to Phone B. The FortiGate accepts the 100 OK response. The SIP ALG translates the Phone A addresses back to the SIP proxy server virtual IP address before forwarding the response back to Phone B. The SIP ALG also opens a pinhole using the SIP proxy server virtual IP which is the address in the o= line of the SDP profile and the port number in the m= line of the SDP code.

SIP destination NAT scenario part 2: 200 OK returned to Phone B and media streams established

The media stream from Phone A is accepted by pinhole one and forwarded to Phone B. The source address of this media stream is changed to the SIP proxy server virtual IP address. The media stream from Phone B is accepted by pinhole 2 and forwarded to Phone B. The destination address of this media stream is changed to the IP address of Phone A.

SIP NAT configuration example: source address translation (source NAT)

This configuration example shows how to configure the FortiGate to support the source address translation scenario shown below. The FortiGate requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A. Both of these policies must include source NAT. In this example the networks are not hidden from each other so destination NAT is not required.

SIP source NAT configuration

General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - GUI

To add firewall addresses for the SIP phones

1. Go to **Policy & Objects > Addresses**.
2. Add the following addresses for Phone A and Phone B:

Category	Address
Name	Phone_A
Type	IP/Netmask
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	Internal

Category	Address
Name	Phone_B
Type	IP/Netmask
Subnet / IP Range	172.20.120.30/255.255.255.255
Interface	wan1

To add security policies to apply the SIP ALG to SIP sessions

1. Go to **Policy & Objects > Policy > IPv4**.
2. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Incoming Interface	internal
Outgoing Interface	wan1
Source	Phone_A
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

3. Turn on **NAT** and select **Use Outgoing Interface Address**.
4. Turn on **VoIP** and select the **default** VoIP profile.
5. Select **OK**.
6. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Incoming Interface	wan1
Outgoing Interface	internal
Source	Phone_B
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

7. Turn on **NAT** and select **Use Outgoing Interface Address**.
8. Turn on **VoIP** and select the **default** VoIP profile.
9. Select **OK**.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
  edit Phone_A
    set associated interface internal
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
  edit Phone_B
    set associated interface wan1
    set type ipmask
    set subnet 172.20.120.30 255.255.255.255
end
```

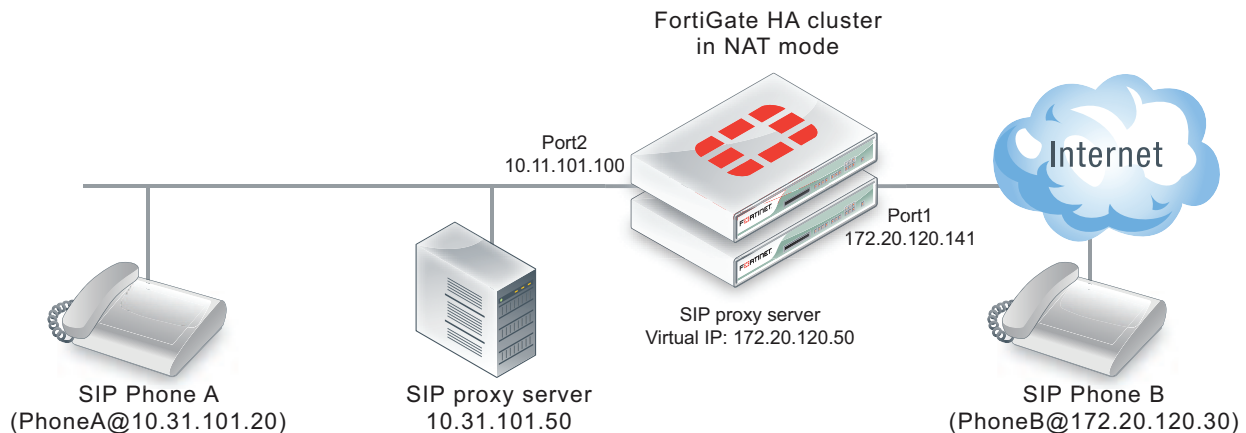

2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set voip-profile default
  next
  edit 0
    set srcintf wan1
    set dstintf internal
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set voip-profile default
end
```

SIP NAT configuration example: destination address translation (destination NAT)

This configuration example shows how to configure the FortiGate to support the destination address translation scenario shown in the figure below. The FortiGate requires two SIP security policies:

- A destination NAT security policy that allows SIP messages to be sent from the Internet to the private network. This policy must include destination NAT because the addresses on the private network are not routable on the Internet.
- A source NAT security policy that allows SIP messages to be sent from the private network to the Internet.

SIP destination NAT scenario part two: 200 OK returned to Phone B and media streams established**General configuration steps**

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1. Add the SIP proxy server firewall virtual IP.
2. Add a firewall address for the SIP proxy server on the private network.
3. Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.
4. Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - GUI**To add the SIP proxy server firewall virtual IP**

1. Go to **Policy & Objects > Virtual IPs**.
2. Add the following SIP proxy server virtual IP.

VIP Type	IPv4
Name	SIP_Proxy_VIP
Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1. Go to **Policy & Objects > Addresses**.
2. Add the following for the SIP proxy server:

Address Name	SIP_Proxy_Server
Type	Subnet
Subnet/IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1. Go to **Policy & Objects > IPv4 Policy**.
2. Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Incoming Interface	port1
Outgoing Interface	port2
Source	all
Destination Address	SIP_Proxy_VIP
Schedule	always
Service	SIP
Action	ACCEPT

3. Turn on **NAT** and select **Use Outgoing Interface Address**.
4. Turn on **VoIP** and select the **default** VoIP profile.
5. Select **OK**.
6. Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Incoming Interface	port2
Destination Address	all
Source	SIP_Proxy_Server
Schedule	always
Service	SIP
Action	ACCEPT

7. Turn on **NAT** and select **Use OutgoingInterface Address**.
8. Turn on **VoIP** and select the **default** VoIP profile.
9. Select **OK**.

Configuration steps - CLI

To add the SIP proxy server firewall virtual IP and firewall address

1. Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
edit SIP_Proxy_VIP
set type static-nat
set extip 172.20.120.50
set mappedip 10.31.101.50
set extintf port1
end
```

2. Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
edit SIP_Proxy_Server
set associated interface port2
set type ipmask
set subnet 10.31.101.50 255.255.255.255
end
```

To add security policies

1. Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

```
config firewall policy
edit 0
set srcintf port1
set dstintf port2
set srcaddr all
set dstaddr SIP_Proxy_VIP
set action accept
set schedule always
set service SIP
set nat enable
set utm-status enable
set voip-profile default
end
```

2. Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

```
config firewall policy
edit 0
set srcintf port2
set dstintf port1
set srcaddr SIP_Proxy_Server
set dstaddr all
set action accept
set schedule always
set service SIP
set nat enable
set utm-status enable
set voip-profile default
end
```

SIP and RTP source NAT

In the source NAT scenario shown below, a SIP phone connects to the Internet through a FortiGate with an IP address configured using PPPoE. The SIP ALG translates all private IPs in the SIP contact header into public IPs.

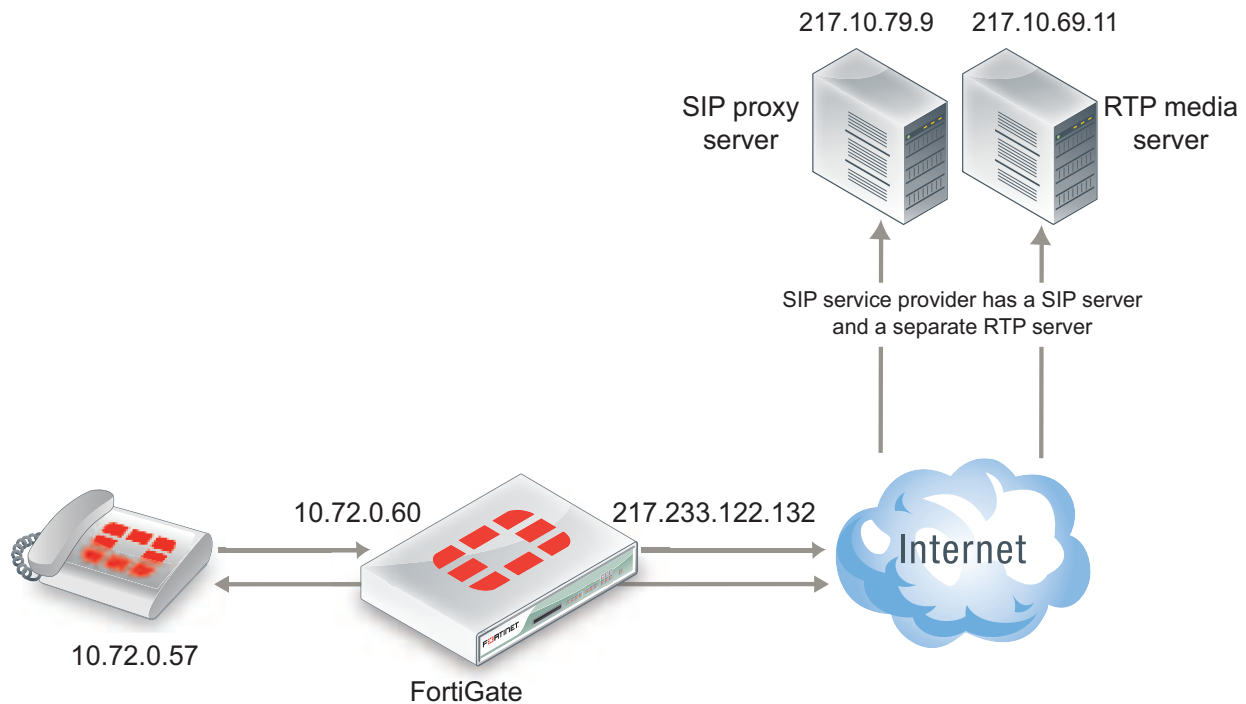

You need to configure an internal to external SIP security policy with NAT selected, and include a VoIP profile with SIP enabled.

SIP source NAT

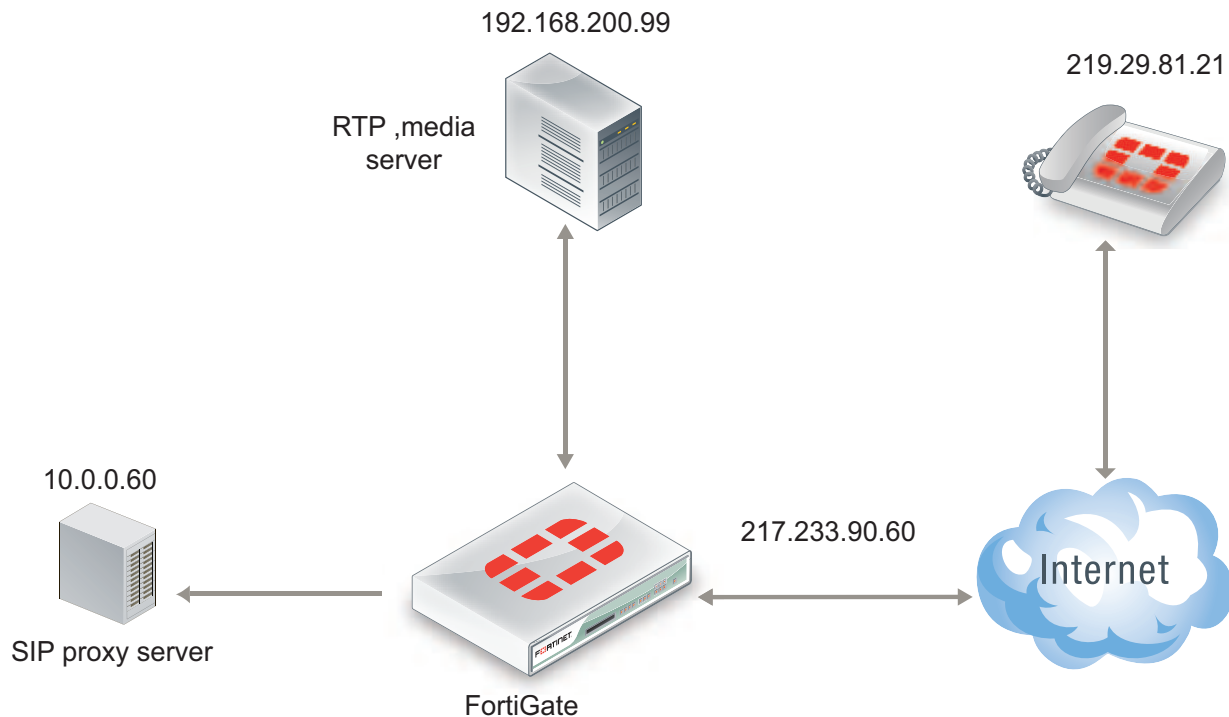

SIP and RTP destination NAT

In the following destination NAT scenario, a SIP phone can connect through the FortiGate to a private IP address using a firewall virtual IP (VIP). The SIP ALG translates the SIP contact header to the IP of the real SIP proxy server located on the Internet.

SIP destination NAT

In the scenario, shown above, the SIP phone connects to a VIP (10.72.0.60). The SIP ALG translates the SIP contact header to 217.10.79.9, opens RTP pinholes, and manages NAT.

The FortiGate also supports a variation of this scenario where the RTP media server's IP address is hidden on a private network or DMZ.

SIP destination NAT-RTP media server hidden

In the scenario shown above, a SIP phone connects to the Internet. The VoIP service provider only publishes a single public IP. The FortiGate is configured with a firewall VIP. The SIP phone connects to the FortiGate (217.233.90.60) and using the VIP the FortiGate translates the SIP contact header to the SIP proxy server IP address (10.0.0.60). The SIP proxy server changes the SIP/SDP connection information (which tells the SIP phone which RTP media server IP it should contact) also to 217.233.90.60.

Source NAT with an IP pool

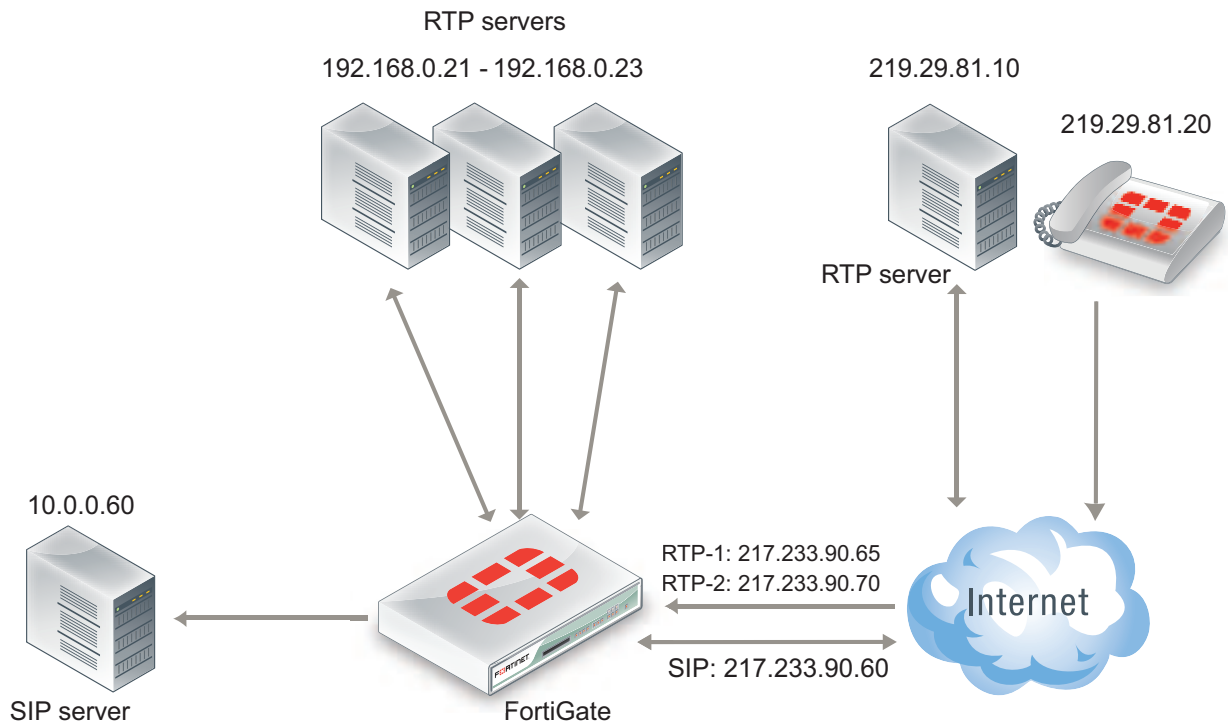

You can choose **NAT** with the **Dynamic IP Pool** option when configuring a security policy if the source IP of the SIP packets is different from the interface IP. The FortiGate ALG interprets this configuration and translates the SIP header accordingly.

This configuration also applies to destination NAT.

Different source and destination NAT for SIP and RTP

This is a more complex scenario that a SIP service provider may use. It can also be deployed in large-scale SIP environments where RTP has to be processed by the FortiGate and the RTP server IP has to be translated differently than the SIP server IP.

Different source and destination NAT for SIP and RTP

In this scenario, shown above, assume there is a SIP server and a separate media gateway. The SIP server is configured so that the SIP phone (219.29.81.20) will connect to 217.233.90.60. The media gateway (RTP server: 219.29.81.10) will connect to 217.233.90.65.

What happens is as follows:

1. The SIP phone connects to the SIP VIP. The FortiGate ALG translates the SIP contact header to the SIP server: 219.29.81.20 > 217.233.90.60 (> 10.0.0.60).
2. The SIP server carries out RTP to 217.233.90.65.
3. The FortiGate ALG opens pinholes, assuming that it knows the ports to be opened.
4. RTP is sent to the RTP-VIP (217.233.90.65.) The FortiGate ALG translates the SIP contact header to 192.168.0.21.

NAT with IP address conservation

In a source or destination NAT security policy that accepts SIP sessions, you can configure the SIP ALG or the SIP session helper to preserve the original source IP address of the SIP message in the `i=` line of the SDP profile. NAT with IP address conservation (also called SIP NAT tracing) changes the contents of SIP messages by adding the source IP address of the originator of the message into the SDP `i=` line of the SIP message. The SDP `i=` line is used for free-form text. However, if your SIP server can retrieve information from the SDP `i=` line, it can be useful for keeping a record of the source IP address of the originator of a SIP message when operating in a NAT environment. You can use this feature for billing purposes by extracting the IP address of the originator of the message.

Configuring SIP IP address conservation for the SIP ALG

You can use the following command to enable or disable SIP IP address conservation in a VoIP profile for the SIP ALG. SIP IP address conservation is enabled by default in a VoIP profile.

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set nat-trace disable
    end
  end
```

If the SIP message does not include an `i=` line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate would add the following `i=` line.

```
i=(o=IN IP4 10.31.101.20)
```

You can also use the `preserve-override` option to configure the SIP ALG to either add the original `o=` line to the end of the `i=` line or replace the `i=` line in the original message with a new `i=` line in the same form as above for adding a new `i=` line.

By default, `preserve-override` is disabled and the SIP ALG adds the original `o=` line to the end of the original `i=` line. Use the following command to configure the SIP ALG to replace the original `i=` line:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set preserve-override enable
    end
  end
```

Configuring SIP IP address conservation for the SIP session helper

You can use the following command to enable or disable SIP IP address conservation for the SIP session helper. IP address conservation is enabled by default for the SIP session helper.

```
config system settings
  set sip-nat-trace disable
end
```

If the SIP message does not include an `i=` line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate would add the following `i=` line.

```
i=(o=IN IP4 10.31.101.20)
```

Controlling how the SIP ALG NATs SIP contact header line addresses

You can enable `contact-fixup` so that the SIP ALG performs normal SIP NAT translation to SIP contact headers as SIP messages pass through the FortiGate.

Disable `contact-fixup` if you do not want the SIP ALG to perform normal NAT translation of the SIP contact header if a Record-Route header is also available. If `contact-fixup` is disabled, the FortiGate ALG does the following with contact headers:

- For Contact in Requests, if a Record-Route header is present and the request comes from the external network, the SIP Contact header is not translated.
- For Contact in Responses, if a Record-Route header is present and the response comes from the external network, the SIP Contact header is not translated.

If `contact-fixup` is disabled, the SIP ALG must be able to identify the external network. To identify the external network, you must use the `config system interface` command to set the `external` keyword to `enable` for the interface that is connected to the external network.

Enter the following command to perform normal NAT translation of the SIP contact header:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set contact-fixup enable
    end
  end
```

Controlling NAT for addresses in SDP lines

You can use the `no-sdp-fixup` option to control whether the FortiGate performs NAT on addresses in SDP lines in the SIP message body.

The `no-sdp-fixup` option is disabled by default and the FortiGate performs NAT on addresses in SDP lines. Enable this option if you don't want the FortiGate to perform NAT on the addresses in SDP lines.

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set no-sdp-fixup enable
    end
  end
```

Translating SIP session destination ports

Using port forwarding virtual IPs you can change the destination port of SIP sessions as they pass through the FortiGate.

Translating SIP sessions to a different destination port

To configure translating SIP sessions to a different destination port you must add a static NAT virtual IP that translates the SIP destination port to another port destination. In the example the destination port is translated from 5060 to 50601. This configuration can be used if SIP sessions use different destination ports on different networks.

Example translating SIP sessions to a different destination port**To translate SIP sessions to a different destination port**

1. Add the static NAT virtual IP.

This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

```
config firewall vip
  edit "sip_port_trans_vip"
    set type static-nat
    set portforward enable
    set protocol tcp
    set extip 172.20.120.20
    set extport 5060
    set extintf "port1"
    set mappedip 192.168.10.20
    set mappedport 50601
    set comment "Translate SIP destination port"
  end
```

2. Add a security policy that includes the virtual IP and the default VoIP profile.

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "all"
```

```

set dstaddr "sip_port_trans_vip"
set action accept
set schedule "always"
set service "ANY"
set utm-status enable
set profile-protocol-options default
set comments "Translate SIP destination port"
end

```

Translating SIP sessions to multiple destination ports

You can use a load balance virtual IP to translate SIP session destination ports to a range of destination ports. In this example the destination port is translated from 5060 to the range 50601 to 50603. This configuration can be used if your SIP server is configured to receive SIP traffic on multiple ports.

Example translating SIP traffic to multiple destination ports

To translated SIP sessions to multiple destination ports

1. Add the load balance virtual IP.

This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

```
config firewall vip
```

```

edit "sip_port_ldbl_vip"
    set type load-balance
    set portforward enable
    set protocol tcp
    set extip 172.20.120.20
    set extport 5060
    set extintf "port1"
    set mappedip 192.168.10.20
    set mappedport 50601-50603
    set comment "Translate SIP destination port range"
end

```

2. Add a security policy that includes the virtual IP and VoIP profile.

```

config firewall policy
    edit 1
        set srcintf "port1"
        set dstintf "port2"
        set srcaddr "all"
        set dstaddr "sip_port_ldbl_vip"
        set action accept
        set schedule "always"
        set service "ANY"
        set utm-status enable
        set voip-profile default
        set comments "Translate SIP destination port"
    end

```

Adding the original IP address and port to the SIP message header after NAT

In some cases your SIP configuration may require that the original IP address and port from the SIP contact request is kept after NAT. For example, the original SIP contact request could include the following:

```
Contact: <sip:0150302438@172.20.120.110:5060>;
```

After the packet goes through the FortiGate and NAT is performed, the contact request could normally look like the following (the IP address translated to a different IP address and the port to a different port):

```
Contact: <sip:0150302438@10.10.10.21:33608>;
```

You can enable `register-contact-trace` in a VoIP profile to have the SIP ALG add the original IP address and port in the following format:

```
Contact: <sip:0150302438@<nated-ip>:<nated-port>;o=<original-ip>: <original-port>>;
```

So the contact line after NAT could look like the following:

```
Contact: <sip:0150302438@10.10.10.21:33608;o=172.20.120.110:5060>;
```

Enter the following command to enable keeping the original IP address and port:

```

config voip profile
    edit Profile_name
        config sip
            set register-contract-trace enable
        end
    end

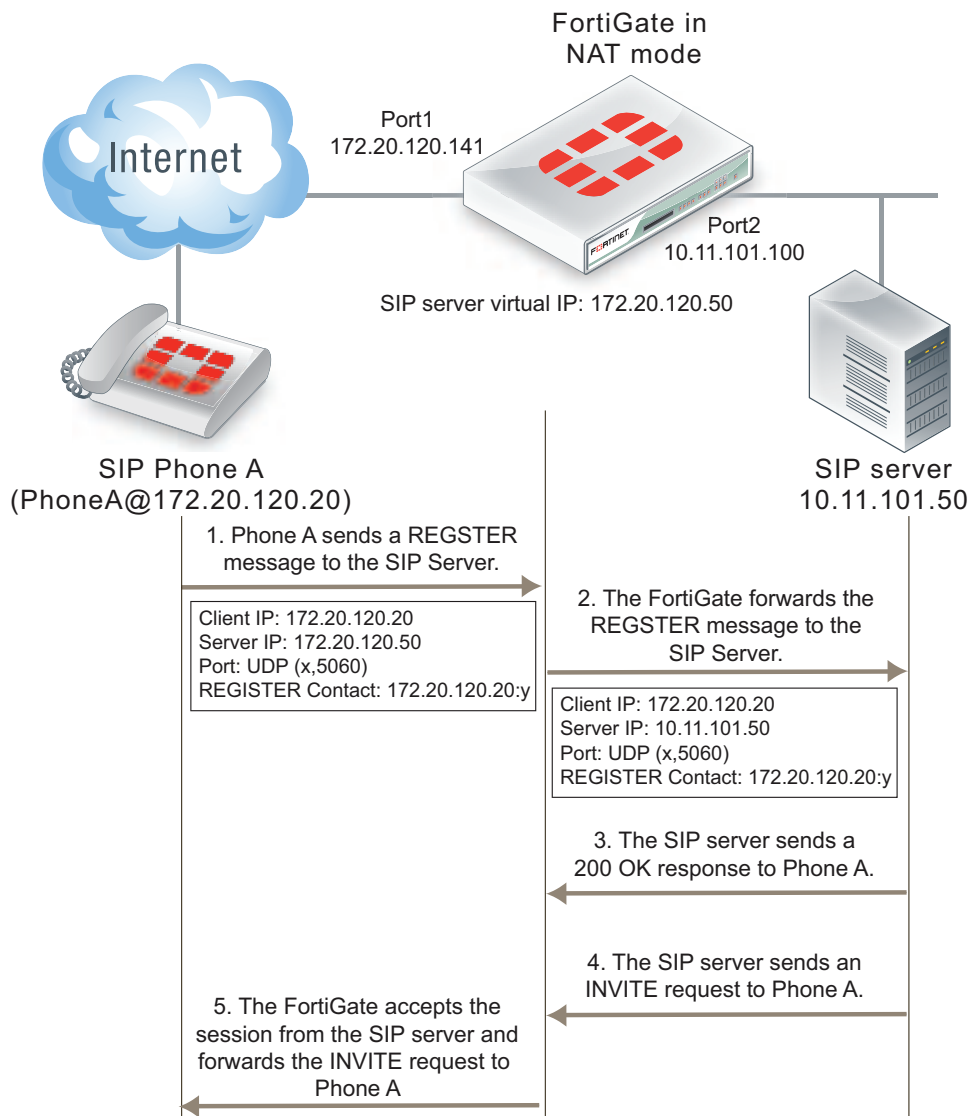

```

Enhancing SIP pinhole security

You can use the `strict-register` option in a SIP VoIP profile to open smaller pinholes. This option is enabled by default on the default VoIP profiles and in all new VoIP profiles that you create.

As shown below, when FortiGate is protecting a SIP server on a private network, the FortiGate does not have to open a pinhole for the SIP server to send INVITE requests to a SIP Phone on the Internet after the SIP Phone has registered with the server.

FortiGate protecting a SIP server on a private network

In the example, a client (SIP Phone A) sends a REGISTER request to the SIP server with the following information:

```
Client IP: 10.31.101.20
Server IP: 10.21.101.50
```

```
Port: UDP (x,5060)
REGISTER Contact: 10.31.101.20:y
```

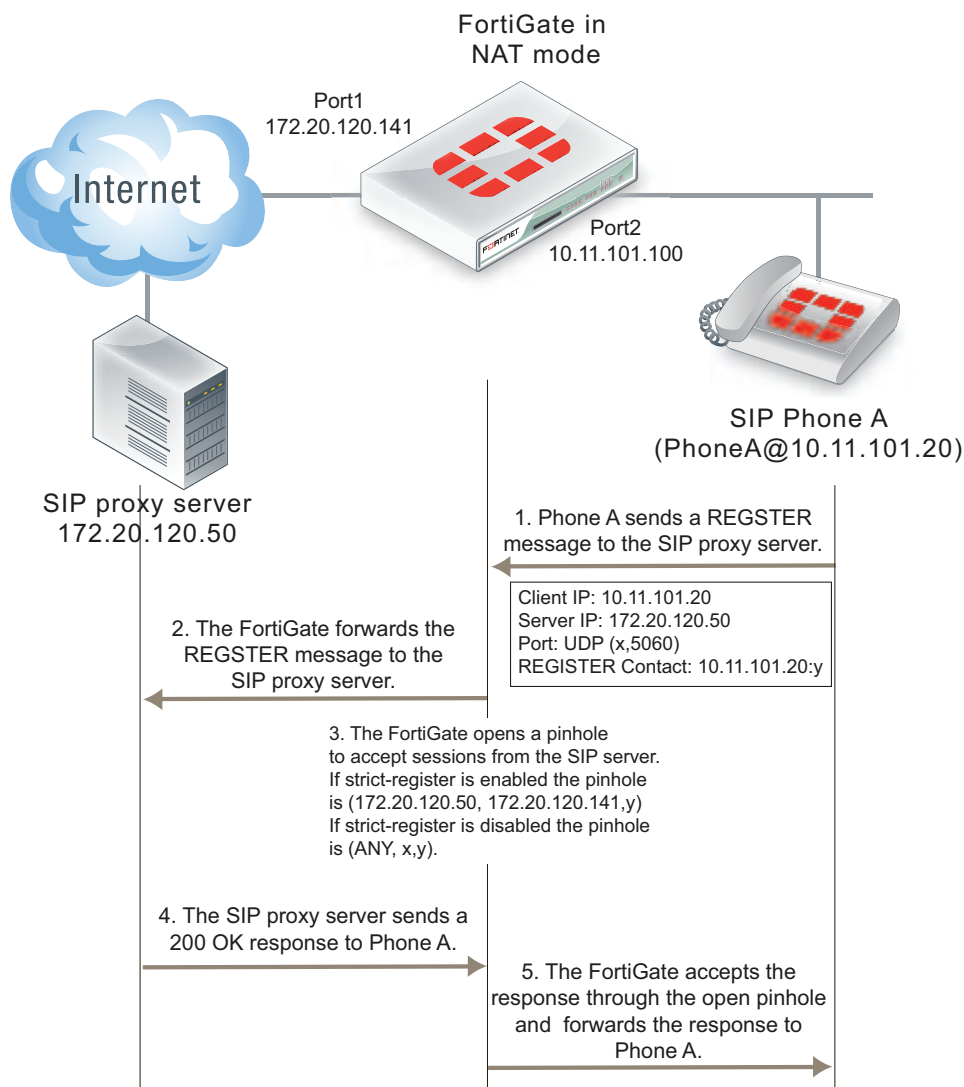

Where *x* and *y* are ports chosen by Phone A.

As soon as the server sends the 200 OK reply it can forward INVITE requests from other SIP phones to SIP Phone A. If the SIP proxy server uses the information in the REGISTER message received from SIP Phone A the INVITE messages sent to Phone A will only get through the FortiGate if a policy has been added to allow the server to send traffic from the private network to the Internet. Or the SIP ALG must open a pinhole to allow traffic from the server to the Internet. In most cases the FortiGate is protecting the SIP server so there is no reason not to add a security policy to allow the SIP server to send outbound traffic to the Internet.

In a typical SOHO scenario, shown below, SIP Phone A is being protected from the Internet by a FortiGate. In most cases the FortiGate would not allow incoming traffic from the Internet to reach the private network. So the only way that an INVITE request from the SIP server can reach SIP Phone A is if the SIP ALG creates an incoming pinhole. All pinholes have three attributes:

```
(source address, destination address, destination port)
```

SOHO configuration, FortiGate protecting a network with SIP phones

The more specific a pinhole is the more secure it is because it accept less traffic. In this situation, the pinhole would be more secure if it only accepted traffic from the SIP server. This is what happens if `strict-register` is enabled in the VoIP profile that accepts the REGISTER request from Phone A.

(SIP server IP address, client IP address, destination port)

If `strict-register` is disabled (the default configuration) the pinhole is set up with the following attributes

(ANY IP address, client IP address, destination port)

This pinhole allows connections through the FortiGate from ANY source address which is a much bigger and less secure pinhole. In most similar network configurations you should enable `strict-register` to improve pinhole security.

Enabling `strict-register` can cause problems when the SIP registrar and SIP proxy server are separate entities with separate IP addresses.

Enter the following command to enable `strict-register` in a VoIP profile.

```
config voip profile
  edit Profile_name
    config sip
      set strict-register enable
    end
```

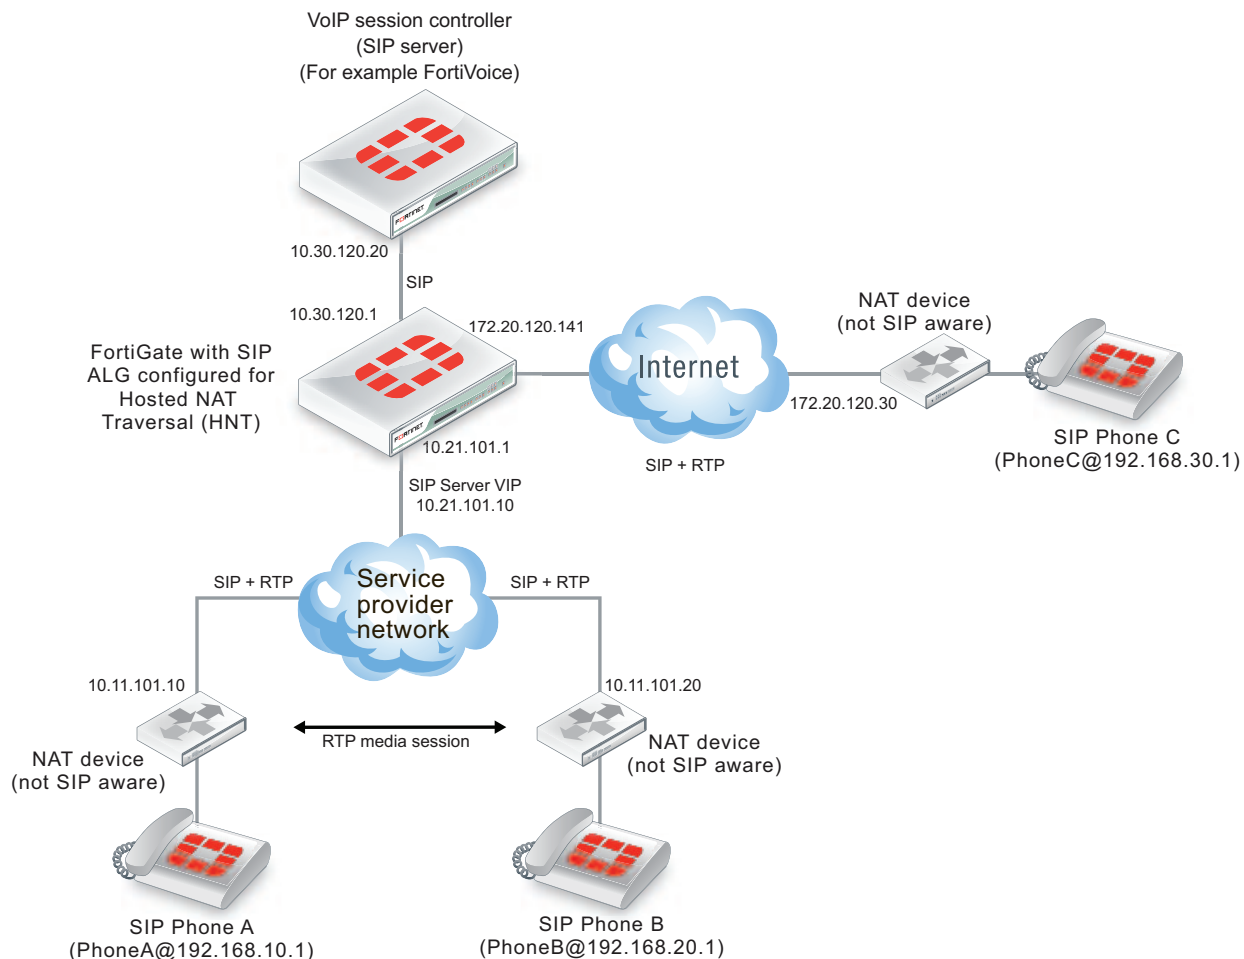

Hosted NAT traversal

With the increase in the use of VoIP and other media traffic over the Internet, service provider network administrators must defend their networks from threats while allowing voice and multimedia traffic to flow transparently between users and servers and among users. A common scenario could involve providing SIP VoIP services for customers with SIP phones installed behind NAT devices that are not SIP aware. NAT devices that are not SIP aware cannot translate IP addresses in SIP headers and SDP lines in SIP packets but can and do perform source NAT on the source or addresses of the packets. In this scenario the user's SIP phones would communicate with a SIP proxy server to set up calls between SIP phones. Once the calls are set up RTP packets would be communicated directly between the phones through each user's NAT device.

The problem with this configuration is that the SIP headers and SDP lines in the SIP packets sent from the phones and received by the SIP proxy server would contain the private network addresses of the VoIP phones that would not be routable on the service provider network or on the Internet. One solution could be to for each customer to install and configure SIP aware NAT devices. If this is not possible, another solution requires implement hosted NAT traversal.

In a hosted NAT traversal (HNT) configuration, a FortiGate is installed between the NAT device and the SIP proxy server and configured with a VoIP profile that enables SIP hosted NAT traversal. Security policies that include the VoIP profile also support destination NAT using a firewall virtual IP. When the SIP phones connect to the SIP server IP address the security policy accepts the SIP packets, the virtual IP translates the destination addresses of the packets to the SIP server IP address, and the SIP ALG NAT traversal configuration translates the source IP addresses on the SIP headers and SDP lines to the source address of the SIP packets (which would be the external IP address of the NAT devices). The SIP server then sees the SIP phone IP address as the external IP address of the NAT device. As a result SIP and RTP media sessions are established using the external IP addresses of the NAT devices instead of the actual IP addresses of the SIP phones.

FortiGate SIP Hosted NAT Traversal configuration

Configuration example: Hosted NAT traversal for calls between SIP Phone A and SIP Phone B

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone B in the above diagram.

1. SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1, destination IP address: 10.21.101.10.
2. The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.20.
3. The SIP packets are received by the FortiGate which translates the packet destination IP address to 10.30.120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.
4. The SIP server accepts the Invite message and forwards it to SIP Phone B at IP address 10.11.101.20. The SIP server has this address for SIP Phone B because SIP packets from SIP Phone B have also been translated using the hosted NAT traversal configuration of the SIP ALG.

5. When the SIP call is established, the RTP session is between 10.11.101.10 and 10.11.101.20 and does not pass through the FortiGate. The NAT devices translated the destination address of the RTP packets to the private IP addresses of the SIP phones.

General configuration steps

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1. Add a VoIP profile that enables hosted NAT translation.
2. Add a SIP proxy server firewall virtual IP.
3. Add a firewall address for the SIP proxy server on the private network.
4. Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.
5. Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - GUI

To add the SIP proxy server firewall virtual IP

1. Go to **Policy & Objects > Virtual IPs**.
2. Add the SIP proxy server virtual IP.

Name	SIP_Proxy_VIP
External Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1. Go to **Policy & Objects > Addresses**.
2. Add the following for the SIP proxy server:

Category	Address
Name	SIP_Proxy_Server
Type	Subnet
Subnet / IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1. Go to **Policy & Objects > IPv4 Policy**.
2. Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Incoming Interface	port1
Outgoing Interface	port2
Source	all
Destination Address	SIP_Proxy_VIP
Schedule	always
Service	SIP
Action	ACCEPT

3. Turn on **NAT** and select **Use Outgoing Interface Address**.
4. Turn on **VoIP** and select the **default** VoIP profile.
5. Select **OK**.
6. Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Incoming Interface	port2
Outgoing Interface	port1
Source	SIP_Proxy_Server
Destination Address	all
Schedule	always
Service	SIP
Action	ACCEPT

7. Turn on **NAT** and select **Use Outgoing Interface Address**.
8. Turn on **VoIP** and select the **default** VoIP profile.
9. Select **OK**.

Configuration steps - CLI**To add a VoIP profile that enables hosted NAT translation**

1. Enter the following command to add a VoIP profile named HNT that enables hosted NAT traversal. This command shows how to clone the default VoIP profile and enable hosted NAT traversal.

```
config voip profile
  clone default to HNT
```

```
edit HNT
  config sip
    set hosted-nat-traversal enable
  end
end
```

To add the SIP proxy server firewall virtual IP and firewall address

1. Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
  edit SIP_Proxy_VIP
    set type static-nat
    set extip 10.21.101.10
    set mappedip 10.30.120.20
    set extintf port1
  end
```

2. Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
  edit SIP_Proxy_Server
    set associated interface port2
    set type ipmask
    set subnet 10.30.120.20 255.255.255.255
  end
```

To add security policies

1. Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone A to send SIP request messages to the SIP proxy server.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr SIP_Proxy_VIP
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile HNT
  end
```

2. Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B:

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr SIP_Proxy_Server
    set dstaddr all
    set action accept
    set schedule always
    set service SIP
    set nat enable
```

```
set utm-status enable
set profile-protocol-options default
set voip-profile default
end
```

Hosted NAT traversal for calls between SIP Phone A and SIP Phone C

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone C in the previous diagram.

1. SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1 and destination IP address: 10.21.101.10.
2. The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.10.
3. The SIP packets are received by the FortiGate which translates the packet destination IP address to 10.30.120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.
4. The SIP server accepts the Invite message and forwards it to SIP Phone C at IP address 172.20.120.30. The SIP server has this address for SIP Phone C because SIP packets from SIP Phone C have also been translated using the hosted NAT traversal configuration of the SIP ALG.
5. When the SIP call is established, the RTP session is between 10.11.101.10 and 172.20.120.30. The packets pass through the FortiGate which performs NAT as required.

Restricting the RTP source IP

Use the following command in a VoIP profile to restrict the RTP source IP to be the same as the SIP source IP when hosted NAT traversal is enabled.

```
config voip profile
  edit VoIP_HNT
    config sip
      set hosted-nat-traversal enable
      set hnt-restrict-source-ip enable
    end
  end
```

SIP over IPv6

FortiGates operating in NAT/Route and in transparent mode support SIP over IPv6. The SIP ALG can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGates cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown in the figure below, a SIP phone connects to the Internet through a FortiGate operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.

SIP support for IPv6

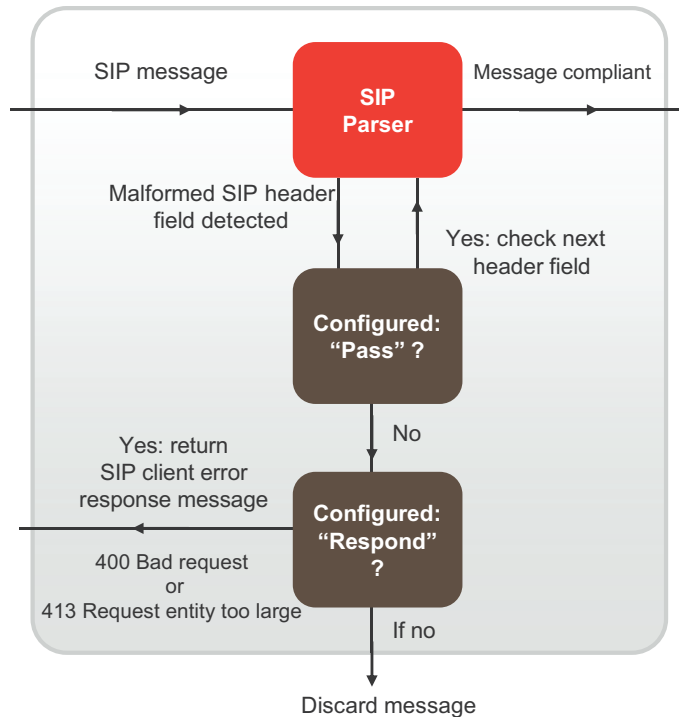

To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

Deep SIP message inspection

Deep SIP message syntax inspection (also called Deep SIP header inspection or SIP fuzzing protection) provides protection against malicious SIP messages by applying SIP header and SDP profile syntax checking. SIP Fuzzing attacks can be used by attackers to discover and exploit vulnerabilities of a SIP entity (for example a SIP proxy server). Most often these attacks could crash or compromise the SIP entity.

Deep SIP message inspection

- Checks the SIP request message Request-line
- Checks the following SIP header fields:
 - Allow, Call-id, Contact, Content-length, Content-type, CSeq, Expires, From, Max-Forwards, P-asserted-identity, Rack, Record-Route, Route, Rseq, To, Via
- Checks all SDP profile lines
- Configurable header and body length checks
- Optional logging of message violations

Deep SIP message inspection checks the syntax of each SIP header and SDP profile line to make sure they conform to the syntax defined in the relevant RFC and IETF standard. You can also configure the SIP ALG to inspect for:

- Unknown SIP message types (message types not defined in a SIP RFC) this option is enabled by default and can be disabled. When enabled unknown message types are discarded. Configured using the `block-unknown` option.
- Unknown line types (message line types that are not defined in any SIP or SDP RFC). Configured using the `unknown-header` option.
- Messages that are longer than a configured maximum size. Configured using the `max-body-length` option.
- Messages that contain one or more lines that are longer than a set maximum line length (default 998 characters). Configured using the `max-line-length` option.

Actions taken when a malformed message line is found

When a malformed message line or other error is found the SIP ALG can be configured to discard the message containing the error, pass the message without any other actions, or responding to the message with a 400 Bad Request or 413 Request entity too large client error SIP response message and then discard the message. (For information about client error SIP response messages, see [Client error on page 3108](#).)

If a message line is longer than the configured maximum, the SIP ALG sends the following message:

```
SIP/2.0 413 Request Entity Too Large, <optional_info>
```

If a message line is incorrect or in an unknown message line is found, the SIP ALG sends the following message:

```
SIP/2.0 400 Bad Request, <optional_info>
```

The `<optional_info>` provides more information about why the message was rejected. For example, if the SIP ALG finds a malformed Via header line, the response message may be:

```
SIP/2.0 400 Bad Request, malformed Via header
```

If the SIP ALG finds a malformed message line, and the action for this message line type is discard, the message is discarded with no further checking or responses. If the action is pass, the SIP ALG continues parsing the SIP message for more malformed message lines. If the action is respond, the SIP ALG sends the SIP response message and discards the message containing the malformed line with no further checking or response. If only malformed message line types with action set to pass are found, the SIP ALG extracts as much information as possible from the message (for example for NAT and opening pinholes, and forwards the message to its destination).

If a SIP message containing a malformed line is discarded the SIP ALG will not use the information in the message for call processing. This could result in the call being terminated. If a malformed line in a SIP message includes information required for the SIP call that the SIP ALG cannot interpret (for example, if an IP address required for SIP NAT is corrupted) the SIP ALG may not be able to continue processing the call and it could be terminated. Discarded messages are counted by SIP ALG static message counters.

Logging and statistics

To record a log message each time the SIP ALG finds a malformed header, enable logging SIP violations in a VoIP profile. In all cases, when the SIP ALG finds an error the FortiGate records a malformed header log message that contains information about the error. This happens even if the action is set to pass.

If, because of recording log messages for deep message inspection, the CPU performance is affected by a certain amount, the FortiGate records a critical log message about this event and stops writing log messages for deep SIP message inspection.

The following information is recorded in malformed header messages:

- The type of message line in which the error was found.
- The content of the message line in which the error was found (it will be truncated if it makes the log message too long)
- The column or character number in which the error was found (to make it easier to determine what caused the error)

Deep SIP message inspection best practices

Because of the risks imposed by SIP header attacks or incorrect data being allowed and because selecting drop or respond does not require more CPU overhead than pass you would want to set all tests to drop or respond.

However, in some cases malformed lines may be less of a threat or risk. For example, the SDP `i=` does not usually contain information that is parsed by any SIP device so a malformed `i=` line may not pose a threat.

You can also use the pre-defined VoIP profiles to apply different levels of deep message inspection. The default VoIP profile sets all deep message inspection options to pass and the strict VoIP profile sets all deep message inspection options to discard. From the CLI you can use the `clone` command to copy these pre-defined VoIP profiles and then customize them for your requirements.

Configuring deep SIP message inspection

You configure deep SIP message inspection in a VoIP profile. All deep SIP message inspection options are available only from the CLI.

Enter the following command to configure deep SIP message inspection to discard messages with malformed Request-lines (the first line in a SIP request message):

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set malformed-request-line respond
    end
  end
```

You cannot configure message inspection for the Status-line, which is the first line in a SIP response message.

The following table lists the SIP header lines that the SIP ALG can inspect and the CLI command for configuring the action for each line type. The table also lists the RFC that the header line is defined in.

SIP header lines that the SIP ALG can inspect for syntax errors

SIP Header line	VoIP profile option	RFC
Allow	<code>malformed-header-allow</code>	RFC 3261
Call-ID	<code>malformed-header-call-id</code>	RFC 3261
Contact	<code>malformed-header-contact</code>	RFC 3261
Content-Length	<code>malformed-header-content-length</code>	RFC 3261
Content-Type	<code>malformed-header-content-type</code>	RFC 3261

P-Asserted-Identity	malformed-header-p-asserted-identity	RFC 3325
RAck	malformed-header-rack	RFC 3262
Record-Route	malformed-header-record-route	RFC 3261
Route	malformed-header-route	RFC 3261
RSeq	malformed-header-rseq	RFC 3262
To	malformed-header-to	RFC 3261
Via	malformed-header-via	RFC 3261

The table below lists the SDP profile lines that the SIP ALG inspects and the CLI command for configuring the action for each line type. SDP profile lines are defined by RFC 4566 and RFC 2327.

SDP profile lines that the SIP ALG can inspect for syntax errors

Attribute	VoIP profile option
a=	malformed-header-sdb-a
b=	malformed-header-sdp-b
c=	malformed-header-sdp-c
i=	malformed-header-sdp-i
k=	malformed-header-sdp-k
m=	malformed-header-sdp-m
o=	malformed-header-sdp-o
r=	malformed-header-sdp-r
s=	malformed-header-sdp-s
t=	malformed-header-sdp-t
v=	malformed-header-sdp-v
z=	malformed-header-sdp-z

Discarding SIP messages with some malformed header and body lines

Enter the following command to configure deep SIP message inspection to discard SIP messages with a malformed Via line, a malformed route line or a malformed m= line but to pass messages with a malformed i= line or a malformed Max-Forwards line

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set malformed-header-via discard
      set malformed-header-route discard
      set malformed-header-sdp-m discard
      set malformed-header-sdp-i pass
      set malformed-header-max-forwards pass
    end
  end
```

Discarding SIP messages with an unknown SIP message type

Enter the following command to discard SIP messages with an unknown SIP message line type as defined in all current SIP RFCs:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set unknown-header discard
    end
  end
```

Discarding SIP messages that exceed a message size

Enter the following command to set the maximum size of a SIP message to 200 bytes. Messages longer than 200 bytes are discarded.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-body-length 200
    end
  end
```

The `max-body-length` option checks the value in the SIP Content-Length header line to determine body length. The Content-Length can be larger than the actual size of a SIP message if the SIP message content is split over more than one packet. SIP message sizes vary widely. The size of a SIP message can also change with the addition of Via and Record-Route headers as the message is transmitted between users and SIP servers.

Discarding SIP messages with lines longer than 500 characters

Enter the following command to set the length of a SIP message line to 500 characters and to block messages that include lines with 500 or more characters:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-line-length 500
      set block-long-lines enable
    end
  end
```

Blocking SIP request messages

You may want to block different types of SIP requests:

- to prevent SIP attacks using these messages.
- If your SIP server cannot process some SIP messages because of a temporary issue (for example a bug that crashes or compromises the server when it receives a message of a certain type).
- Your SIP implementation does not use certain message types.

When you enable message blocking for a message type in a VoIP profile, whenever a security policy containing the VoIP profile accepts a SIP message of this type, the SIP ALG silently discards the message and records a log message about the action.

Use the following command to configure a VoIP profile to block SIP CANCEL and Update request messages:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set block-cancel enable
      set block-update enable
    end
  end
```

SIP uses a variety of text-based messages or requests to communicate information about SIP clients and servers to the various components of the SIP network. Since SIP requests are simple text messages and since the requests or their replies can contain information about network components on either side of the FortiGate, it may be a security risk to allow these messages to pass through.

The following table lists all of the VoIP profile SIP request message blocking options. All of these options are disabled by default.

Blocking SIP OPTIONS messages may prevent a redundant configuration from operating correctly. See [Supporting geographic redundancy when blocking OPTIONS messages on page 3191](#) for information about resolving this problem.

Options for blocking SIP request messages

SIP request message	SIP message blocking CLI Option
ACK	block-ack
BYE	block-bye
Cancel	block-cancel
INFO	block-info
INVITE	block-invite

SIP request message	SIP message blocking CLI Option
Message	block-message
Notify	block-notify
Options	block-options
PRACK	block-prack
Publish	block-publish
Refer	block-refer
Register	block-register
Subscribe	block-subscribe
Update	block-update

SIP rate limiting

Configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.

SIP rate limiting

FortiGate supports rate limiting for the following types of VoIP traffic:

- Session Initiation Protocol (SIP)
- Skinny Call Control Protocol (SCCP) (most versions)
- Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE).

You can use rate limiting of these VoIP protocols to protect the FortiGate and your network from SIP and SCCP Denial of Service (DoS) attacks. Rate limiting protects against SIP DoS attacks by limiting the number of SIP REGISTER and INVITE requests that the FortiGate receives per second. Rate limiting protects against SCCP DoS attacks by limiting the number of SCCP call setup messages that the FortiGate receives per minute.

You configure rate limiting for a message type by specifying a limit for the number of messages that can be received per second. The rate is limited per security policy. When VoIP rate limiting is enabled for a message type, if the a single security policy accepts more messages per second than the configured rate, the extra messages are dropped and log messages are written when the messages are dropped.

Use the following command to configure a VoIP profile to limit the number of INVITE messages accepted by each security policy that the VoIP profile is added to 100 INVITE messages a second:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set invite-rate 100
    end
  end
```

If you are experiencing denial of service attacks from traffic using these VoIP protocols, you can enable VoIP rate limiting and limit the rates for your network. Limit the rates depending on the amount of SIP and SCCP traffic that you expect the FortiGate to be handling. You can adjust the settings if some calls are lost or if the amount of SIP or SCCP traffic is affecting FortiGate performance.

The table below lists all of the VoIP profile SIP rate limiting options. All of these options are set to 0 so are disabled by default.

Blocking SIP OPTIONS messages may prevent a redundant configuration from operating correctly. See [Supporting geographic redundancy when blocking OPTIONS messages on page 3191](#) for information about resolving this problem.

Options for SIP rate limiting

SIP request message	Rate Limiting CLI Option
ACK	ack-rate
BYE	bye-rate
Cancel	cancel-rate
INFO	info-rate
INVITE	invite-rate
Message	message-rate
Notify	notify-rate
Options	options-rate
PRACK	prack-rate
Publish	publish-rate

SIP request message	Rate Limiting CLI Option
Refer	refer-rate
Register	register-rate
Subscribe	subscribe-rate
Update	update-rate

Limiting the number of SIP dialogs accepted by a security policy

In addition to limiting the rates for receiving SIP messages, you can use the following command to limit the number of SIP dialogs (or SIP calls) that the FortiGate accepts.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-dialogs 2000
    end
  end
```

This command sets the maximum number of SIP dialogs that can be open for SIP sessions accepted by any security policy that you add the VoIP profile to. The default setting of 0 does not limit the number of dialogs. You can add a limit to control the number of open dialogs and raise and lower it as required. You might want to limit the number of open dialogs for protection against SIP-based attackers opening large numbers of SIP dialogs. Every dialog takes memory and FortiGate CPU resources to process. Limiting the number of dialogs may improve the overall performance of the FortiGate. Limiting the number of dialogs will not drop calls in progress but may prevent new calls from connecting.

SIP logging

You can enable SIP logging and logging of SIP violations in a VoIP profile.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set log-call-summary enable
      set log-violations enable
    end
  end
```

To view SIP log messages go to **Log & Report > Forward Traffic**.

Inspecting SIP over SSL/TLS (secure SIP)

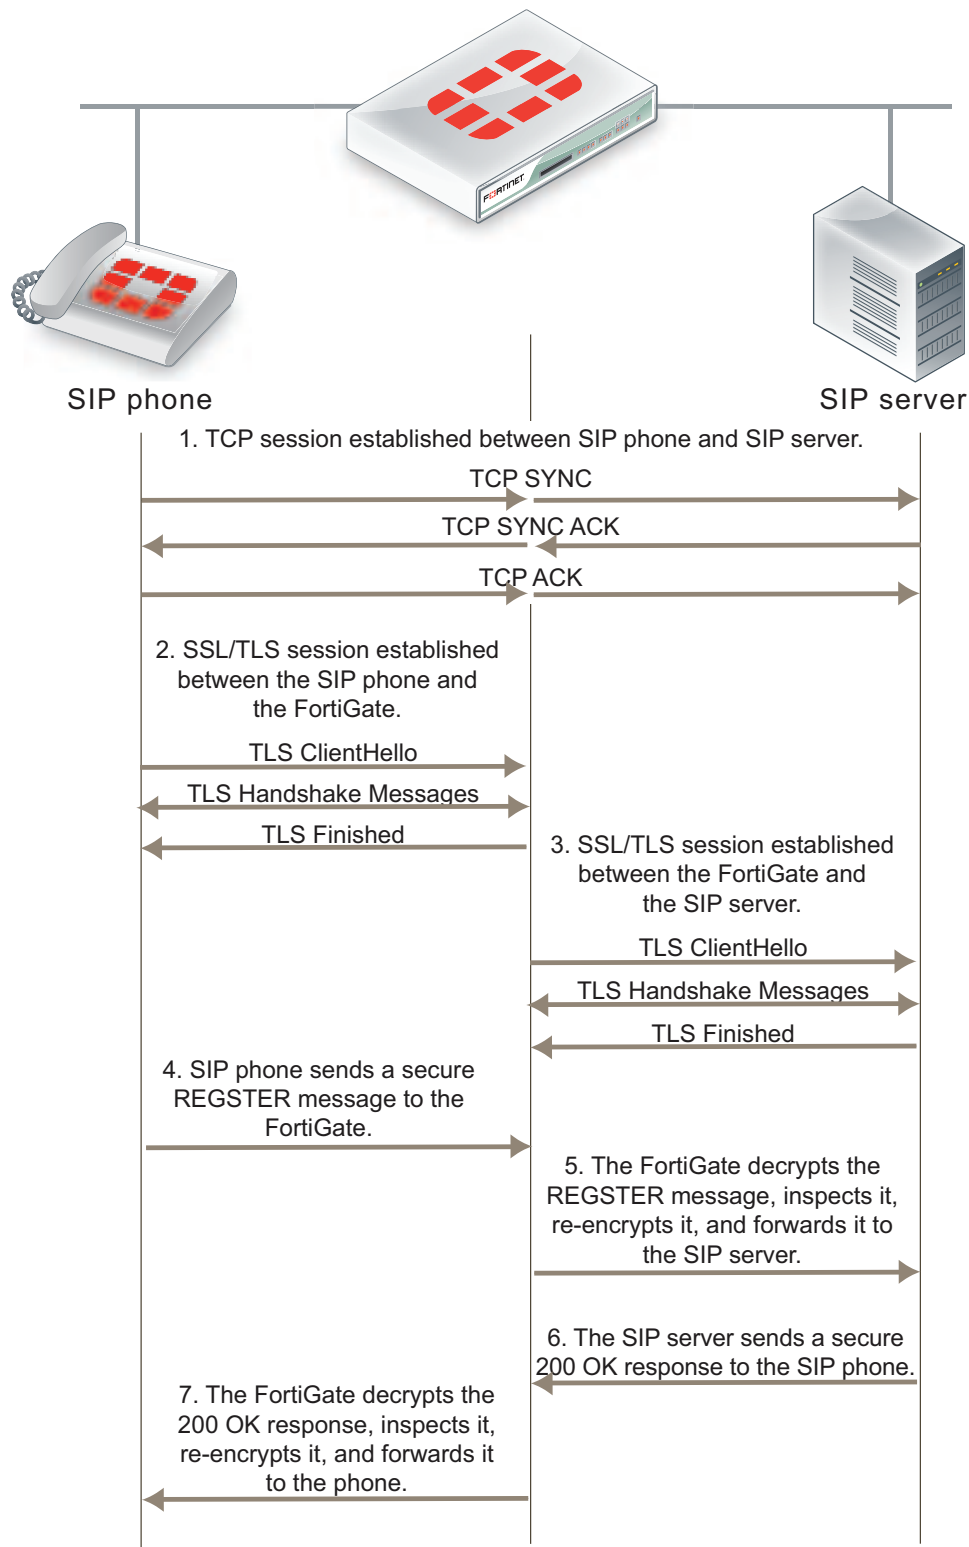

Some SIP phones and SIP servers can communicate using SSL or TLS to encrypt the SIP signaling traffic. To allow SIP over SSL/TLS calls to pass through the FortiGate, the encrypted signaling traffic has to be unencrypted and inspected. To do this, the FortiGate SIP ALG intercepts and unencrypts and inspects the SIP packets. The packets are then re-encrypted and forwarded to their destination.

Normally SIP over SSL/TLS uses port 5061. You can use the following command to change the port that the FortiGate listens on for SIP over SSL/TLS sessions to port 5066:

```
config system settings
    set sip-ssl-port 5066
end
```

The SIP ALG supports full mode SSL/TLS only. Traffic between SIP phones and the FortiGate and between the FortiGate and the SIP server is always encrypted.

You enable SSL/TLS SIP communication by enabling SSL mode in a VoIP profile. You also need to install the SIP server and client certificates on your FortiGate and add them to the SSL configuration in the VoIP profile.

SIP over SSL/TLS between a SIP phone and a SIP server

Other than enabling SSL mode and making sure the security policies accept the encrypted traffic, the FortiGate configuration for SSL/TLS SIP is the same as any SIP configuration. SIP over SSL/TLS is supported for all supported SIP configurations.

Adding the SIP server and client certificates

A VoIP profile that supports SSL/TLS SIP requires one certification for the SIP server and one certificate that is used by all of the clients. Use the following steps to add these certificates to the FortiGate. Before you start, make sure the client and server certificate files and their key files are accessible from the management computer.

1. Go to **System > Certificates** and select **Import**.
2. Set **Type** to **Certificate**.
3. Browse to the **Certificate file** and the **Key file** and select **OK**.
4. Enter a password for the certificate and select **OK**.
The certificate and key are uploaded to the FortiGate and added to the **Local Certificates** List.
5. Repeat to upload the other certificate.

The certificates are added to the list of Local Certificates as the filenames you uploaded. You can add comments to make it clear where its from and how it is intended to be used.

Adding SIP over SSL/TLS support to a VoIP profile

Use the following commands to add SIP over SSL/TLS support to the default VoIP profile. The following command enables SSL mode and adds the client and server certificates and passwords, the same ones you entered when you imported the certificates:

```
config voip profile
  edit default
    config sip
      set ssl-mode full
      set ssl-client-certificate "Client_cert"
      set ssl-server-certificate "Server_cert"
      set ssl-auth-client "check-server"
      set ssl-auth-server "check-server-group"
    end
  end
```

Other SSL mode options are also available:

<code>ssl-send-empty-frags {disable enable}</code>	Enable to send empty fragments to avoid CBC IV attacks. Compatible with SSL 3.0 and TLS 1.0 only. Default is <code>enable</code> .
<code>ssl-client-renegotiation {allow deny secure}</code>	Control how the ALG responds when a client attempts to renegotiate the SSL session. You can allow renegotiation or block sessions when the client attempts to renegotiate. You can also select <code>secure</code> to reject an SSL connection that does not support RFC 5746 secure renegotiation indication. Default is <code>allow</code> .

<code>ssl-algorithm {high low medium}</code>	Select the relative strength of the algorithms that can be selected. You can select <code>high</code> , the default, to allow only AES or 3DES, <code>medium</code> , to allow AES, 3DES, or RC4 or <code>low</code> , to allow AES, 3DES, RC4, or DES.
<code>ssl-pfs {allow deny require}</code>	Select whether to allow, deny, or require perfect forward secrecy (PFS). Default is <code>allow</code> .
<code>ssl-min-version {ssl-3.0 tls-1.0 tls-1.1}</code>	Select the minimum level of SSL support to allow. The default is <code>ssl-3.0</code> .
<code>ssl-max-version {ssl-3.0 tls-1.0 tls-1.1}</code>	Select the maximum level of SSL support to allow. The default is <code>tls-1.1</code> .

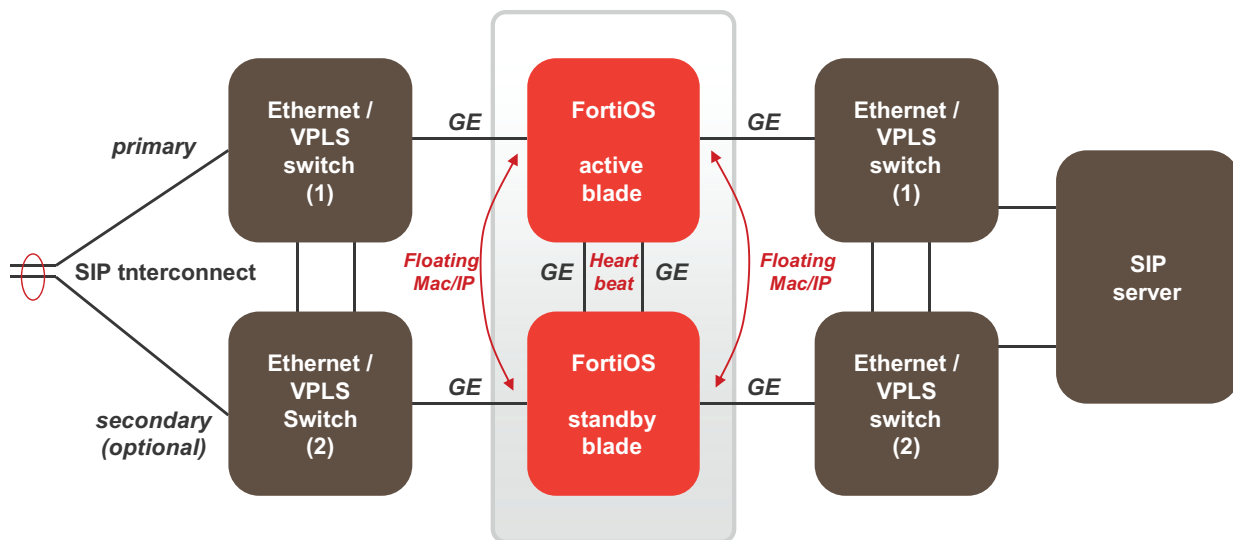

SIP and HA-session failover and geographic redundancy

FortiGate active-passive high availability (HA) supports SIP UDP session failover (also called stateful failover) if the SIP sessions are processed by the SIP ALG. To support SIP UDP session failover, create a standard HA configuration and select the enable **Session Pick-up** option.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in-progress SIP UDP calls (setup complete) and their RTP flows are maintained and the calls continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA failover occurs. But in most cases the call setup should be able to continue after the failover.

SIP HA session failover

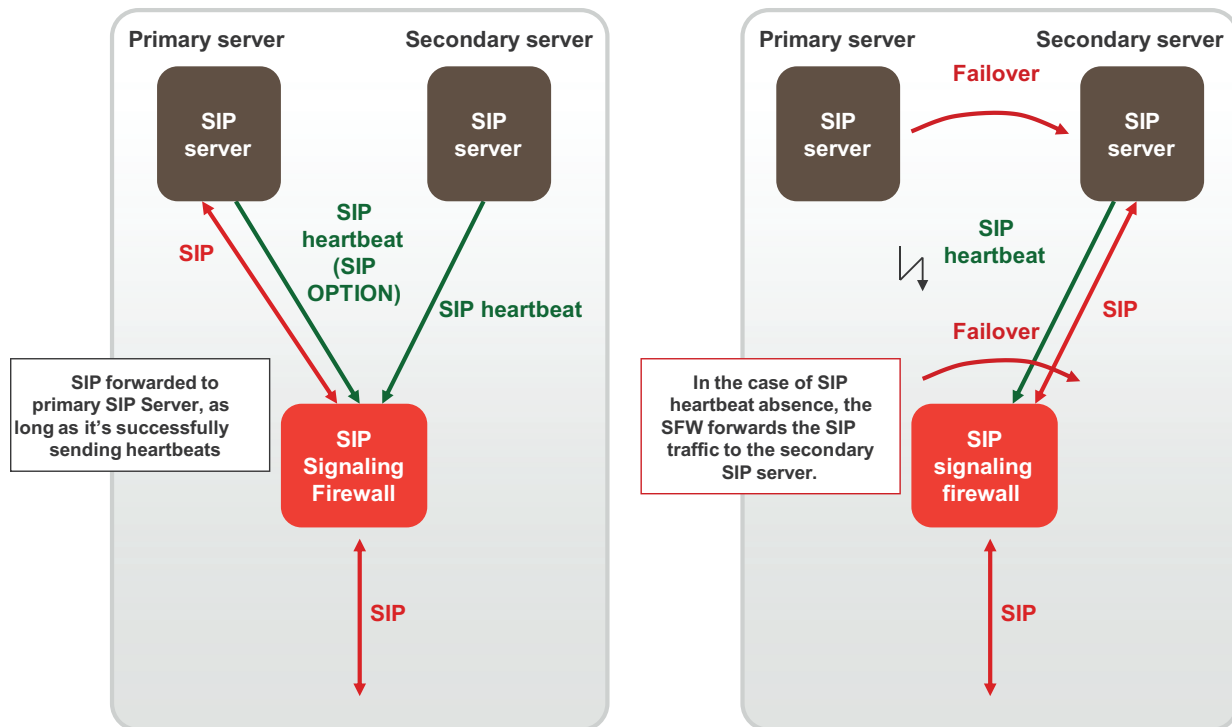

In some cases, failover during call tear down can result in hanging RTP connections that can accumulate over time and use up system memory. If this becomes a problem, you can set a time for the `call-keepalive` SIP VoIP profile setting. This setting causes the FortiGate to terminate calls with no activity after the time limit has exceeded. Range is 1 to 10,080 seconds. This options should be used with caution because it results in extra FortiGate CPU overhead and can cause delay and jitter for the VoIP call. Also, the FortiGate terminates the call without sending SIP messages to end the call. And if the SIP endpoints send SIP messages to terminate the call they will be blocked by the FortiGate if they are sent after the FortiGate terminates the call.

SIP geographic redundancy

Maintains a active-standby SIP server configuration, which even supports geographical distribution. If the active SIP server fails (missing SIP heartbeat messages or SIP traffic) FortiOS will redirect the SIP traffic to a secondary SIP server. No special configuration is required for geographic redundancy, just standard HA configuration.

Geographic redundancy

Supporting geographic redundancy when blocking OPTIONS messages

For some geographic redundant SIP configurations, the SIP servers may use SIP OPTIONS messages as heartbeats to notify the FortiGate that they are still operating (or alive). This is a kind of passive SIP monitoring mechanism where the FortiGate isn't actively monitoring the SIP servers and instead the FortiGate passively receives and analyzes OPTIONS messages from the SIP servers.

If FortiGates block SIP OPTIONS messages because `block-options` is enabled, the configuration may fail to operate correctly because the OPTIONS messages are blocked by one or more FortiGates.

However, you can work around this problem by enabling the `block-geo-red-options` application control list option. This option causes the FortiGate to refresh the local SIP server status when it receives an OPTIONS message before dropping the message. The end result is the heartbeat signals between geographically redundant SIP servers are maintained but OPTIONS messages do not pass through the FortiGate.

Use the following command to block OPTIONS messages while still supporting geographic redundancy:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set block-options disable
      set block-geo-red-options enable
    end
  end
```

The `block-options` option setting overrides the `block-geo-red-options` option. If `block-options` is enabled the FortiGate only blocks SIP OPTIONS messages and does not refresh local SIP server status.

Support for RFC 2543-compliant branch parameters

RFC 3261 is the most recent SIP RFC, it obsoletes RFC 2543. However, some SIP implementations may use RFC 2543-compliant SIP calls.

The `rfc2543-branch` VoIP profile option allows the FortiGate to support SIP calls that include an RFC 2543-compliant branch parameter in the SIP Via header. This option also allows FortiGates to support SIP calls that include Via headers that are missing the branch parameter.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set rfc2543-branch enable
    end
  end
```

SIP and IPS

You can enable IPS in security policies that also accept SIP sessions to protect the SIP traffic from SIP-based attacks. If you enable IPS in this way then by default the pinholes that the SIP ALG creates to allow RTP and RTCP to flow through the firewall will also have IPS enabled.

This inheritance of the IPS setting can cause performance problems if the RTP traffic volume is high since IPS checking may reduce performance in some cases. Also if you are using network processor (NP) interfaces to accelerate VoIP performance, when IPS is enabled for the pinhole traffic is diverted to the IPS and as a result is not accelerated by the network processors.

You can use the following CLI command to disable IPS for the RTP pinhole traffic.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set ips-rtp disable
    end
  end
```

SIP debugging

This chapter includes some information to help with debugging SIP configurations.

SIP debug log format

Assuming that diagnose debug console timestamp is enabled then the following shows the debug that is generated for an INVITE if diag debug appl sip -1 is enabled:

```
2010-01-04 21:39:59 sip port 26 locate session for 192.168.2.134:5061 ->
172.16.67.192:5060
2010-01-04 21:39:59 sip sess 0x979df38 found for 192.168.2.134:5061 ->

SIP-proxy filter per VDOM

You can use the `diagnose sys sip-proxy xxx` command in a VDOM to get info about how SIP is operating in each VDOM.

SIP-proxy filter command

Use the `diagnose system sip-proxy filter` to filter diagnose information for the SIP ALG. The following filters are available:

```
diag sys sip-proxy filter vd
diag sys sip-proxy filter dst-addr4
diag sys sip-proxy filter dst-addr6
diag sys sip-proxy filter dst-port
diag sys sip-proxy filter identity-policy
diag sys sip-proxy filter negate
diag sys sip-proxy filter policy
diag sys sip-proxy filter policy-type
diag sys sip-proxy filter profile-group
diag sys sip-proxy filter src-addr4
diag sys sip-proxy filter src-addr6
diag sys sip-proxy filter src-port
diag sys sip-proxy filter vd
diag sys sip-proxy filter voip-profile
```

You can clear, view and negate/invert the sense of a filter using these commands:

```
diag sys sip-proxy filter clear
diag sys sip-proxy filter list
diag sys sip-proxy filter negate
```

SIP debug setting

Control of the SIP debug output is governed by the following command

```
diagnose debug application sip <debug_level_int>
```

Where the `<debug_level_int>` is a bitmask and the individual values determine whether the listed items are logged or not. The `<debug_level_int>` can be:

- | | |
|---|--|
| 1 | Configuration changes, mainly addition/deletion/modification of virtual domains. |
| 2 | TCP connection accepts or connects, redirect creation. |

4	Create or delete a session.
16	Any IO read or write.
32	An ASCII dump of all data read or written.
64	Include HEX dump in the above output.
128	Any activity related to the use of the FortiCarrier dynamic profile feature to determine the correct profile-group to use.
256	Log summary of interesting fields in a SIP call.
1024	Any activity related to SIP geo-redundancy.
2048	Any activity related to HA syncing of SIP calls.

Display SIP rate-limit data

You can use the `diagnose sys sip-proxy meters` command to display SIP rate limiting data.

For the following command output `rate 1` shows that the current (over last second) measured rate for INVITE/ACK and BYE was 1 per second, the `peak 1` shows that the peak rate recorded is 1 per second, the `max 0` shows that there is no maximum limit set, the `count 18` indicates that 18 messages were received and `drop 0` indicates that none were dropped due to being over the limit.

```

diagnose sys sip-proxy meters
sip
sip vd: 0
sip policy: 1
sip identity-policy: 0
sip policy-type: IPv4
sip profile-group:
sip dialogs: 18
sip dialog-limit: 0
sip UNKNOWN: rate 0 peak 0 max 0 count 0 drop 0
sip ACK: rate 1 peak 1 max 0 count 18 drop 0
sip BYE: rate 1 peak 1 max 0 count 18 drop 0
sip CANCEL: rate 0 peak 0 max 0 count 0 drop 0
sip INFO: rate 0 peak 0 max 0 count 0 drop 0
sip INVITE: rate 1 peak 1 max 0 count 18 drop 0
sip MESSAGE: rate 0 peak 0 max 0 count 0 drop 0
sip NOTIFY: rate 0 peak 0 max 0 count 0 drop 0
sip OPTIONS: rate 0 peak 0 max 0 count 0 drop 0
sip PRACK: rate 0 peak 0 max 0 count 0 drop 0
sip PUBLISH: rate 0 peak 0 max 0 count 0 drop 0
sip REFER: rate 0 peak 0 max 0 count 0 drop 0
sip REGISTER: rate 0 peak 0 max 0 count 0 drop 0
sip SUBSCRIBE: rate 0 peak 0 max 0 count 0 drop 0
sip UPDATE: rate 0 peak 0 max 0 count 0 drop 0
sip PING: rate 0 peak 0 max 0 count 0 drop 0
sip YAHOOREF: rate 0 peak 0 max 0 count 0 drop 0

```

Supported RFCs

This document lists the RFCs that FortiOS supports.

What's new in FortiOS 6.0.1

FortiOS 6.0.1 introduces support for the following RFCs:

- [RFC 4389](#): Neighbor Discovery Proxies (ND Proxy)
- [RFC 5282](#): Using Authenticated Encryption Algorithms with the Encrypted Payload of the Internet Key Exchange version 2 (IKEv2) Protocol

What's new in FortiOS 6.0

FortiOS 6.0 introduces support for the following RFCs:

- [RFC 8031](#): Curve25519 and Curve448 for the Internet Key Exchange Protocol Version 2 (IKEv2) Key Agreement
- [RFC 7634](#): ChaCha20, Poly1305, and Their Use in the Internet Key Exchange Protocol (IKE) and IPsec
- [RFC 5425](#): Transport Layer Security (TLS) Transport Mapping for Syslog

Supported RFCs

FortiOS supports the following RFCs.

BGP

- [RFC 4724](#): Graceful Restart Mechanism for BGP
- [RFC 4456](#): BGP Route Reflection: An Alternative to Full Mesh Internal BGP (IBGP)
- [RFC 4360](#): BGP Extended Communities Attribute
- [RFC 4271](#): A Border Gateway Protocol 4 (BGP-4)
- [RFC 2918](#): Route Refresh Capability for BGP-4
- [RFC 2545](#): Use of BGP-4 Multiprotocol Extensions for IPv6 Inter-Domain Routing
- [RFC 2439](#): BGP Route Flap Damping
- [RFC 1997](#): BGP Communities Attribute
- [RFC 1930](#): Guidelines for creation, selection, and registration of an Autonomous System (AS)
- [RFC 1772](#): Application of the Border Gateway Protocol in the Internet

Cryptography

- [RFC 8031](#): Curve25519 and Curve448 for the Internet Key Exchange Protocol Version 2 (IKEv2) Key Agreement
- [RFC 7634](#): ChaCha20, Poly1305, and Their Use in the Internet Key Exchange Protocol (IKE) and IPsec
- [RFC 7627](#): Transport Layer Security (TLS) Session Hash and Extended Master Secret Extension
- [RFC 7539](#): ChaCha20 and Poly1305 for IETF Protocols
- [RFC 7427](#): Signature Authentication in the Internet Key Exchange Version 2 (IKEv2)
- [RFC 7383](#): Internet Key Exchange Protocol Version 2 (IKEv2) Message Fragmentation
- [RFC 7296](#): Internet Key Exchange Protocol Version 2 (IKEv2)
- [RFC 7027](#): Elliptic Curve Cryptography (ECC) Brainpool Curves for Transport Layer Security (TLS)
- [RFC 6989](#): Additional Diffie-Hellman Tests for the Internet Key Exchange Protocol Version 2 (IKEv2)
- [RFC 6954](#): Using the Elliptic Curve Cryptography (ECC) Brainpool Curves for the Internet Key Exchange Protocol Version 2 (IKEv2)
- [RFC 6290](#): A Quick Crash Detection Method for the Internet Key Exchange Protocol (IKE)
- [RFC 6023](#): A Childless Initiation of the Internet Key Exchange Version 2 (IKEv2) Security Association (SA)
- [RFC 5723](#): Internet Key Exchange Protocol Version 2 (IKEv2) Session Resumption
- [RFC 5282](#): Using Authenticated Encryption Algorithms with the Encrypted Payload of the Internet Key Exchange version 2 (IKEv2) Protocol
- [RFC 5280](#): Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile
- [RFC 4754](#): IKE and IKEv2 Authentication Using the Elliptic Curve Digital Signature Algorithm (ECDSA)
- [RFC 4635](#): HMAC SHA TSIG Algorithm Identifiers
- [RFC 4492](#): Elliptic Curve Cryptography (ECC) Cipher Suites for Transport Layer Security (TLS)
- [RFC 4478](#): Repeated Authentication in Internet Key Exchange (IKEv2) Protocol
- [RFC 4106](#): The Use of Galois/Counter Mode (GCM) in IPsec Encapsulating Security Payload (ESP)
- [RFC 3947](#): Negotiation of NAT-Traversal in the IKE

- [RFC 3602](#): The AES-CBC Cipher Algorithm and Its Use with IPsec
- [RFC 3526](#): More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)
- [RFC 2986](#): PKCS #10: Certification Request Syntax Specification Version 1.7
- [RFC 2845](#): Secret Key Transaction Authentication for DNS (TSIG)
- [RFC 2631](#): Diffie-Hellman Key Agreement Method
- [RFC 2451](#): The ESP CBC-Mode Cipher Algorithms
- [RFC 2410](#): The NULL Encryption Algorithm and Its Use With IPsec
- [RFC 2405](#): The ESP DES-CBC Cipher Algorithm With Explicit IV
- [RFC 2404](#): The Use of HMAC-SHA-1-96 within ESP and AH
- [RFC 2403](#): The Use of HMAC-MD5-96 within ESP and AH
- [RFC 2315](#): PKCS #7: Cryptographic Message Syntax Version 1.5
- [RFC 2104](#): HMAC: Keyed-Hashing for Message Authentication
- [RFC 2085](#): HMAC-MD5 IP Authentication with Replay Prevention
- [RFC 1422](#): Privacy Enhancement for Internet Electronic Mail: Part II: Certificate-Based Key Management
- [RFC 1321](#): The MD5 Message-Digest Algorithm
- [PKCS #12](#): PKCS 12 v1: Personal Information Exchange Syntax

DHCP

- [RFC 4361](#): Node-specific Client Identifiers for Dynamic Host Configuration Protocol Version Four (DHCPv4)
- [RFC 3736](#): Stateless Dynamic Host Configuration Protocol (DHCP) Service for IPv6
- [RFC 3633](#): IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) version 6
- [RFC 3456](#): Dynamic Host Configuration Protocol (DHCPv4) Configuration of IPsec Tunnel Mode
- [RFC 3315](#): Dynamic Host Configuration Protocol for IPv6 (DHCPv6)
- [RFC 2132](#): DHCP Options and BOOTP Vendor Extensions
- [RFC 2131](#): Dynamic Host Configuration Protocol

Diffserv

- [RFC 3260](#): New Terminology and Clarifications for Diffserv
- [RFC 2597](#): Assured Forwarding PHB Group
- [RFC 2475](#): An Architecture for Differentiated Services
- [RFC 2474](#): Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers

DNS

- [RFC 6895](#): Domain Name System (DNS) IANA Considerations
- [RFC 6604](#): xNAME RCODE and Status Bits Clarification
- [RFC 6147](#): DNS64: DNS Extensions for Network Address Translation from IPv6 Clients to IPv4 Servers
- [RFC 4592](#): The Role of Wildcards in the Domain Name System
- [RFC 4035](#): Protocol Modifications for the DNS Security Extensions
- [RFC 4034](#): Resource Records for the DNS Security Extensions
- [RFC 4033](#): DNS Security Introduction and Requirements
- [RFC 3597](#): Handling of Unknown DNS Resource Record (RR) Types

- [RFC 3226](#): DNSSEC and IPv6 A6 aware server/resolver message size requirements
- [RFC 3007](#): Secure Domain Name System (DNS) Dynamic Update
- [RFC 2308](#): Negative Caching of DNS Queries (DNS NCACHE)
- [RFC 2181](#): Clarifications to the DNS Specification
- [RFC 2136](#): Dynamic Updates in the Domain Name System (DNS UPDATE)
- [RFC 1996](#): A Mechanism for Prompt Notification of Zone Changes (DNS NOTIFY)
- [RFC 1995](#): Incremental Zone Transfer in DNS
- [RFC 1982](#): Serial Number Arithmetic
- [RFC 1876](#): A Means for Expressing Location Information in the Domain Name System
- [RFC 1706](#): DNS NSAP Resource Records
- [RFC 1183](#): New DNS RR Definitions
- [RFC 1101](#): DNS Encoding of Network Names and Other Types
- [RFC 1035](#): Domain Names - Implementation and Specification
- [RFC 1034](#): Domain Names - Concepts and Facilities

ICMP

- [RFC 6918](#): Formally Deprecating Some ICMPv4 Message Types
- [RFC 6633](#): Deprecation of ICMP Source Quench Messages
- [RFC 4884](#): Extended ICMP to Support Multi-Part Messages
- [RFC 4443](#): Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification
- [RFC 1191](#): Path MTU Discovery
- [RFC 792](#): Internet Control Message Protocol

IP

- [RFC 5798](#): Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6
- [RFC 4301](#): Security Architecture for the Internet Protocol
- [RFC 3272](#): Overview and Principles of Internet Traffic Engineering
- [RFC 3168](#): The Addition of Explicit Congestion Notification (ECN) to IP
- [RFC 2072](#): Router Renumbering Guide
- [RFC 2071](#): Network Renumbering Overview: Why would I want it and what is it anyway?
- [RFC 1918](#): Address Allocation for Private Internets
- [RFC 1123](#): Requirements for Internet Hosts -- Application and Support
- [RFC 1122](#): Requirements for Internet Hosts -- Communication Layers
- [RFC 791](#): Internet Protocol

IP multicast

- [RFC 5059](#): Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- [RFC 4604](#): Using Internet Group Management Protocol Version 3 (IGMPv3) and Multicast Listener Discovery Protocol Version 2 (MLDv2) for Source-Specific Multicast
- [RFC 3973](#): Protocol Independent Multicast - Dense Mode (PIM-DM): Protocol Specification (Revised)
- [RFC 3956](#): Embedding the Rendezvous Point (RP) Address in an IPv6 Multicast Address

- [RFC 3306](#): Unicast-Prefix-based IPv6 Multicast Addresses
- [RFC 2365](#): Administratively Scoped IP Multicast
- [RFC 1112](#): Host Extensions for IP Multicasting

IPsec

- [RFC 4304](#): Extended Sequence Number (ESN) Addendum to IPsec Domain of Interpretation (DOI) for Internet Security Association and Key Management Protocol (ISAKMP)
- [RFC 4303](#): IP Encapsulating Security Payload (ESP)
- [RFC 3706](#): A Traffic-Based Method of Detecting Dead Internet Key Exchange (IKE) Peers

IPv4

- [RFC 6864](#): Updated Specification of the IPv4 ID Field
- [RFC 5177](#): Network Mobility (NEMO) Extensions for Mobile IPv4
- [RFC 4632](#): Classless Inter-domain Routing (CIDR): The Internet Address Assignment and Aggregation Plan
- [RFC 3927](#): Dynamic Configuration of IPv4 Link-Local Addresses
- [RFC 3021](#): Using 31-Bit Prefixes on IPv4 Point-to-Point Links
- [RFC 1812](#): Requirements for IP Version 4 Routers

IPv6

- [RFC 6343](#): Advisory Guidelines for 6to4 Deployment
- [RFC 5175](#): IPv6 Router Advertisement Flags Option
- [RFC 5095](#): Deprecation of Type 0 Routing Headers in IPv6
- [RFC 4941](#): Privacy Extensions for Stateless Address Autoconfiguration in IPv6
- [RFC 4862](#): IPv6 Stateless Address Autoconfiguration
- [RFC 4861](#): Neighbor Discovery for IP version 6 (IPv6)
- [RFC 4389](#): Neighbor Discovery Proxies (ND Proxy)
- [RFC 4213](#): Basic Transition Mechanisms for IPv6 Hosts and Routers
- [RFC 4193](#): Unique Local IPv6 Unicast Addresses
- [RFC 4007](#): IPv6 Scoped Address Architecture
- [RFC 3971](#): SEcure Neighbor Discovery (SEND)
- [RFC 3596](#): DNS Extensions to Support IP Version 6
- [RFC 3587](#): IPv6 Global Unicast Address Format
- [RFC 3493](#): Basic Socket Interface Extensions for IPv6
- [RFC 3056](#): Connection of IPv6 Domains via IPv4 Clouds
- [RFC 3053](#): IPv6 Tunnel Broker
- [RFC 2894](#): Router Renumbering for IPv6
- [RFC 2675](#): IPv6 Jumbograms
- [RFC 2185](#): Routing Aspects Of IPv6 Transition
- [RFC 1752](#): The Recommendation for the IP Next Generation Protocol

IS-IS

- [RFC 5310](#): IS-IS Generic Cryptographic Authentication
- [RFC 5308](#): Routing IPv6 with IS-IS
- [RFC 3359](#): Reserved Type, Length and Value (TLV) Codepoints in Intermediate System to Intermediate System
- [RFC 1195](#): Use of OSI IS-IS for Routing in TCP/IP and Dual Environments

LDAP

- [RFC 4513](#): Lightweight Directory Access Protocol (LDAP): Authentication Methods and Security Mechanisms
- [RFC 4512](#): Lightweight Directory Access Protocol (LDAP): Directory Information Models
- [RFC 4511](#): Lightweight Directory Access Protocol (LDAP): The Protocol
- [RFC 3494](#): Lightweight Directory Access Protocol version 2 (LDAPv2) to Historic Status

MPLS

- [RFC 7026](#): Retiring TLVs from the Associated Channel Header of the MPLS Generic Associated Channel
- [RFC 6426](#): MPLS On-Demand Connectivity Verification and Route Tracing
- [RFC 6425](#): Detecting Data-Plane Failures in Point-to-Multipoint MPLS - Extensions to LSP Ping
- [RFC 6423](#): Using the Generic Associated Channel Label for Pseudowire in the MPLS Transport Profile (MPLS-TP)
- [RFC 5586](#): MPLS Generic Associated Channel
- [RFC 5462](#): Multiprotocol Label Switching (MPLS) Label Stack Entry: "EXP" Field Renamed to "Traffic Class" Field
- [RFC 5332](#): MPLS Multicast Encapsulations
- [RFC 5129](#): Explicit Congestion Marking in MPLS
- [RFC 4448](#): Encapsulation Methods for Transport of Ethernet over MPLS Networks

- [RFC 5214](#): Intra-Site Automatic Tunnel Addressing Protocol (ISATAP)
- [RFC 4960](#): Stream Control Transmission Protocol
- [RFC 4251](#): The Secure Shell (SSH) Protocol Architecture
- [RFC 3435](#): Media Gateway Control Protocol (MGCP) Version 1.0
- [RFC 3376](#): Internet Group Management Protocol, Version 3
- [RFC 2890](#): Key and Sequence Number Extensions to GRE
- [RFC 2784](#): Generic Routing Encapsulation (GRE)
- [RFC 2661](#): Layer Two Tunneling Protocol "L2TP"
- [RFC 2637](#): Point-to-Point Tunneling Protocol (PPTP)
- [RFC 2412](#): The OAKLEY Key Determination Protocol
- [RFC 2225](#): Classical IP and ARP over ATM
- [RFC 2033](#): Local Mail Transfer Protocol
- [RFC 1413](#): Identification Protocol
- [RFC 1011](#): Official Internet Protocols
- [RFC 862](#): Echo Protocol
- [RFC 768](#): User Datagram Protocol
- [The TACACS+ Protocol](#)

Miscellaneous

- [RFC 7348](#): Virtual eXtensible Local Area Network (VXLAN): A Framework for Overlaying Virtualized Layer 2 Networks over Layer 3 Networks
- [RFC 4784](#): Verizon Wireless Dynamic Mobile IP Key Update for cdma2000(R) Networks for cdma2000(R) Networks
- [RFC 4470](#): Minimally Covering NSEC Records and DNSSEC On-line Signing
- [RFC 3985](#): Pseudo Wire Emulation Edge-to-Edge (PWE3) Architecture
- [RFC 2979](#): Behavior of and Requirements for Internet Firewalls
- [RFC 2827](#): Network Ingress Filtering: Defeating Denial of Service Attacks which employ IP Source Address Spoofing

- [RFC 2780](#): IANA Allocation Guidelines For Values In the Internet Protocol and Related Headers
- [RFC 2647](#): Benchmarking Terminology for Firewall Performance
- [RFC 2644](#): Changing the Default for Directed Broadcasts in Routers
- [RFC 2231](#): MIME Parameter Value and Encoded Word Extensions: Character Sets, Languages, and Continuations
- [RFC 1945](#): Hypertext Transfer Protocol -- HTTP/1.0
- [RFC 950](#): Internet Standard Subnetting Procedure
- [RFC 894](#): A Standard for the Transmission of IP Datagrams over Ethernet Networks
